This report was submitted by The Aerospace Corporation, El Segundo, CA 90245, under Contract No. F04701-85-C-0086 with the Space Division, P. O. Box 92960, Los Angeles AFB CA 90009. It was reviewed and approved for The Aerospace Corporation by H. R. Rugge, Director, Space Sciences Laboratory. Lt Clarence V. Wilcox, SD/CLTPC, was the project officer for the Mission-Oriented Investigation and Experimentation (MOIE) Program.

This report has been reviewed by the Public Affairs Office (PAS) and is releasable to the National Technical Information Service (NTIS). At NTIS, it will be available to the general public, including foreign nations.

This technical report has been reviewed and is approved for publication. Publication of this report does not constitute Air Force approval of the report's findings or conclusions. It is published only for the exchange and stimulation of ideas.

PREFACE

At JPL, special thanks are due to Jim Coss, SEU group leader; the members of the beam team, Carl Malone, George Soli, and Mark Huebner; the device test engineers, Harvey Schwartz, Kevin Watson, and Peter Wang; and the able logistics and trouble-shooting efforts of Mike Havener. The Aerospace authors would like to thank Jon Osborn for producing fast RAM and microprocessor testers, and John Elder for writing extensive software to exercise the test devices, as well as for providing generous help in the analysis of the test results. Thanks are also due to Mike Marra and Bob Walter of Aerospace for constantly updating the experimental hardware and transporting it in good condition to the test site.

Special thanks are due to Ruthmary Larimer and the rest of the staff at the LBL 88-inch cyclotron and to Peter Thieberger and his staff at Brookhaven National Laboratories.

The research described in this paper was performed in part by the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.

I. INTRODUCTION

cont'd
→ An ongoing single event upset (SEU) program at JPL and the Aerospace Corporation is continuing in order to assess specific parts performance in interplanetary and satellite environments and to establish trends in SEU response of many parts types.

In 1985, Nichols et al (Ref. 1) published a nearly comprehensive listing of SEU test data for 186 parts. This large collection was sufficient to permit generalizations about the parts SEU susceptibility according to their technology, function, and manufacturer.

In this report generalizations are extended to newer classes of parts and the statistical base for some of the previous parts classifications is expanded.

↑

II. ORGANIZATION AND SCOPE OF DATA

This report presents soft error and latchup experimental test data from the Jet Propulsion Laboratory (JPL) and the Aerospace Corporation during the period from May 1985 through December 1986. However, data taken for the CRRES satellite ground test program,* and proprietary data taken by DNA subcontractors and others is excluded from this survey. Much smaller data sets have been generated by other U.S. and foreign researchers; these data have not been sought for inclusion in this compilation. The data presented here, nevertheless, represent a substantial majority of all test data obtained throughout the world during this period.

The data from JPL and the Aerospace Corporation are presented in two different groups, and there are minor differences in the format of each organization. JPL defines the threshold LET as that value of LET where soft errors are first counted at fluences of approximately 10^6 ions/cm². Aerospace defines this threshold as occurring at that LET where the measured upset cross section is 10% of the measured maximum cross section. These two values may be very different. To obtain SEU rates for a prescribed radiation environment, one requires a plot of cross section vs. LET, provided by the parent test organization.

The JPL data are conveniently divided into two tables; Table 1 for MOS devices and Table 2 for bipolar devices. The Aerospace data are given in Table 3 for all technologies. All data listed here represent a substantial abbreviation and ignore statistical features altogether. Hence, a system designer interested in a specific part is urged to contact the appropriate test organization for further information.

*Data for the CRRES spacecraft program are stored at JPL, with most of the data presently available to the public.

A. TRENDS

1. JPL DATA

Several interesting trends emerge from this set of data. We see (as indicated before in Ref. 1) that the CMOS RAMs have a varying susceptibility to soft errors as demonstrated by the wide variation in threshold LET; the single bipolar RAM reported here is very soft, as expected. Of special note is the fact that an epi-CMOS part exhibited latchup, reported in Ref. 2.

The single test of a PMOS technology register shows that it has a significantly higher threshold LET than the NMOS devices (DRAMs). However, more testing of PMOS technology is required to establish whether PMOS technology is harder than NMOS technology in general.

The NMOS DRAMs are very susceptible to heavy ion upset and much more susceptible than the 4k KMOS DRAM (MCM6605A) reported earlier (Ref. 1) for which the threshold LET was 14 MeV/mg/cm^2 . One can assume that the high density (large number of bits) for the recently tested parts is relevant. It is also noted that the cross sections for the 256k DRAM can exceed the geometrical area of the sensitive regions. This observation strongly implies that multiple upsets can occur in these devices for a single ion strike. The DRAMs are so sensitive, in fact, that a test with protons or neutrons is recommended to assess their SEU response for avionics, as well as low earth orbit and space applications.

Several PROMS were tested during this period and the data support the expectation that transient upset pulses can occur in PROMs for the heavier ions. Unfortunately, the upset threshold LET was not determined in any of these tests. Note also that latchup was observed in one of the bulk CMOS PROMs at an LET of 14 MeV/mg/cm^2 .

All of the CMOS microprocessors are very soft except for the Harris 80C85 which is an equivalent to a specially hardened microprocessor of the Sandia 3000 series.

Four low power TTL bipolar logic devices were tested, which exhibited good resistance to single event upsets. Noteworthy is the fact that two older

(1974) versions of the 54L93 counter and the 54K73 flip-flop were softer than their newer (1982) equivalents, fabricated by the same manufacturer. This result contrasts with the normal trend where newer equivalent devices are usually more SEU susceptible.

For the first time, data is available on some analog-to-digital (A/D) and digital-to-analog (D/A) converter parts. This limited data subset suggests that A/D converters are more SEU susceptible than the D/A converters.

2. AEROSPACE DATA

The Aerospace data show that two NMOS RAMs, a TTL RAM, and an advanced CMOS technology RAM are all very susceptible to soft errors. The data show that CMOS/SOS and CMOS/epi devices are much harder, as expected.

Preliminary results for a large collection of logic devices show 54AHCTXXX devices are hard whereas 54ASXXX technology is fairly soft. The latter technology resembles the response for 54ALSXXX devices reported earlier (Ref. 1).

III. CONCLUSIONS

The new data presented here, when combined with earlier published data, (Ref. 1) list key SEU device response parameters for some 240 device types. That data base permits many useful generalizations and trends to be established. The data can be used to eliminate unacceptable device technologies and to identify for systems those key parts that are expected to be most SEU susceptible.

LABORATORY OPERATIONS

The Aerospace Corporation functions as an "architect-engineer" for national security projects, specializing in advanced military space systems. Providing research support, the corporation's Laboratory Operations conducts experimental and theoretical investigations that focus on the application of scientific and technical advances to such systems. Vital to the success of these investigations is the technical staff's wide-ranging expertise and its ability to stay current with new developments. This expertise is enhanced by a research program aimed at dealing with the many problems associated with rapidly evolving space systems. Contributing their capabilities to the research effort are these individual laboratories:

Aerophysics Laboratory: Launch vehicle and reentry fluid mechanics, heat transfer and flight dynamics; chemical and electric propulsion, propellant chemistry, chemical dynamics, environmental chemistry, trace detection; spacecraft structural mechanics, contamination, thermal and structural control; high temperature thermomechanics, gas kinetics and radiation; cw and pulsed chemical and excimer laser development including chemical kinetics, spectroscopy, optical resonators, beam control, atmospheric propagation, laser effects and countermeasures.

Chemistry and Physics Laboratory: Atmospheric chemical reactions, atmospheric optics, light scattering, state-specific chemical reactions and radiative signatures of missile plumes, sensor out-of-field-of-view rejection, applied laser spectroscopy, laser chemistry, laser optoelectronics, solar cell physics, battery electrochemistry, space vacuum and radiation effects on materials, lubrication and surface phenomena, thermionic emission, photo-sensitive materials and detectors, atomic frequency standards, and environmental chemistry.

Computer Science Laboratory: Program verification, program translation, performance-sensitive system design, distributed architectures for spaceborne computers, fault-tolerant computer systems, artificial intelligence, micro-electronics applications, communication protocols, and computer security.

Electronics Research Laboratory: Microelectronics, solid-state device physics, compound semiconductors, radiation hardening; electro-optics, quantum electronics, solid-state lasers, optical propagation and communications; microwave semiconductor devices, microwave/millimeter wave measurements, diagnostics and radiometry, microwave/millimeter wave thermionic devices; atomic time and frequency standards; antennas, rf systems, electromagnetic propagation phenomena, space communication systems.

Materials Sciences Laboratory: Development of new materials: metals, alloys, ceramics, polymers and their composites, and new forms of carbon; non-destructive evaluation, component failure analysis and reliability; fracture mechanics and stress corrosion; analysis and evaluation of materials at cryogenic and elevated temperatures as well as in space and enemy-induced environments.

Space Sciences Laboratory: Magnetospheric, auroral and cosmic ray physics, wave-particle interactions, magnetospheric plasma waves; atmospheric and ionospheric physics, density and composition of the upper atmosphere, remote sensing using atmospheric radiation; solar physics, infrared astronomy, infrared signature analysis; effects of solar activity, magnetic storms and nuclear explosions on the earth's atmosphere, ionosphere and magnetosphere; effects of electromagnetic and particulate radiations on space systems; space instrumentation.
