ACKNOWLEDGMENTS

The scientific party from the Arctic Submarine Laboratory provided the primary CTD measurements during the cruise. The authors are grateful to Randall Judd for operating the Neil Brown CTD system and the processing computer. Cooperation of the officers and crew of USCG ice-breaker Polar Sea is greatly appreciated. The satellite images provided by Kristina Ahlnäs of the Geophysical Institute, University of Alaska, were very helpful.

This research was jointly supported by the Office of Naval Technology (ONT) and the Naval Ocean Systems Center (NOSC), with technical management provided by the Naval Ocean Research and Development Activity (NORDA) and the Arctic Submarine Laboratory, NOSC.

ABSTRACT

An oceanographic cruise along the north coast of Alaska and Canada in August and September 1985 reveals evidence of how the Alaskan Coastal Current from the southwest and the Mackenzie River outflow in the eastern portion influence oceanographic conditions in the Beaufort Sea. The coastal current crowds the shore and at depth displaces some of the cold, saline bottom water that drains from the Chukchi Sea through the Barrow Canyon in the spring. The eastward extent of the coastal current is about 148°W longitude, and the westward progression of the Mackenzie River water about 141°W longitude. The ice and weather conditions during the survey appeared to influence water exchange.

I. INTRODUCTION

An icebreaker cruise along the north coast of Alaska in August and September 1985 provided the opportunity to study the influence of the Alaskan Coastal Current, which carries Bering Sea water northward into the Chukchi and Beaufort seas, and of the Mackenzie River, which pours fresh water into the eastern portion of the Beaufort Sea. The area covered by the survey is shown in Figure 1.

Figure 1. Location of the survey off the north coast.

Oceanographic measurements have been made off the north coast of Alaska by the Applied Physics Laboratory since 1971.¹⁻³ The coastal current has been studied extensively.⁴⁻⁷ This northward flow of water is apparently caused by differences⁸ in the levels of the Arctic Ocean and the Bering Sea and is modified by regional atmospheric pressure differences (which sometimes even reverse the direction). As the current moves northward, it draws in the waters of Norton and Kotzebue sounds which have been warmed by the sun. A large part of the resulting mass of warm water moves along the coast from Pt. Hope to Pt. Barrow and enters the Beaufort Sea, where it dissipates into large eddies. Measurements in the Beaufort Sea in the fall of 1980,⁹ 1982,¹⁰ and 1984¹¹ showed thin layers of this warm intrusion as far as 150 miles from the coast. One purpose of the study reported here was to learn what happens to this warm water (up to 10°C). Where does it go? How rapidly does it mix?

Ice cover in the Beaufort Sea often shows a seasonal deterioration which may be due to the warm surface layer caused by runoff from the Mackenzie River. The trajectory and mixing of this plume of warm, fresh water have not been fully documented. Measurements in 1974 and 1975 by Herlinveaux and de Lange Boom¹² showed oceanographic conditions closer to shore and farther east than the present study. Measurements by Huggett et al.¹³ from 1973–1975 gave information on currents near the Mackenzie River outflow and to the east. A second purpose of the 1985 study was to determine the oceanographic influence of the Mackenzie River in the southern Beaufort Sea. Does it become a thin surface layer, or does it mix downward and lose identity?

The cruise started at 134°W longitude, just east of Mackenzie Bay, and progressed westward to Pt. Barrow. The Barrow Canyon area, shown in Figure 2, was then traversed twice, at a 10 day interval, to study not only the warm intrusion but also the distribution of the cold Chukchi water that flows down the Barrow Canyon in the spring and early summer.

Figure 2. Location of the Barrow Canyon.

II. THE CRUISE

The measurements reported here were taken between 17 August and 15 September from USCG icebreaker *Polar Sea* as it cruised along the north coast of Canada and Alaska. The scientific party consisted of cartographer and chief scientist Robert Perry, physicist Edward Floyd, physicist Burton Markham, and oceanographer Randall Judd from the Arctic Submarine Laboratory (ASL) of the Naval Ocean Systems Center (NOSC) and oceanographer Peter Becker from the Applied Physics Laboratory (APL) of the University of Washington. The oceanographic stations consisted mainly of conductivity-temperature-depth (CTD) profiles.

Prior to the cruise, Becker met with Kristina Ahlnäs at the Geophysical Institute of the University of Alaska, Fairbanks, to collect recent satellite images of the area to be traversed and to discuss criteria for satellite coverage during the cruise. Of the potential NOAA satellite coverage available, amounting to some 30 satellite passes, an order was placed for 40% of the imagery during 15–31 August and 60% during 1–15 September, with no coverage east of 148°W after 1 September. LANDSAT coverage was also requested.

The scientific party met at Prudhoe Bay on 14 August, where men and equipment were transferred to the *Polar Sea* by the ship's helicopters.

Hydrographic stations commenced on 17 August enroute to the easternmost station at 134°W longitude. (See Figure 3 for location of stations.) Heavy ice was encountered shortly after leaving Prudhoe Bay. The pack consisted of up to 70% old floes and multiyear ice and extended to within 16–32 km of the coast. Because of the ice, the ship's forward rate of advance was often limited to less than 1 knot the first 6 days of the survey.

Helicopter deployment of ARGOS weather buoys for the Polar Science Center (PSC) of the Applied Physics Laboratory commenced on 23 August and continued at intervals throughout the trip as desired locations were reached or came within helicopter range. Helicopter-supported CTD stations using the APL lightweight CTD profiler were occupied out to 100 km from the ship on parallel tracks to increase coverage and supplement those taken from the slowly moving ship in the heavy ice. Because of the extensive ice cover, attempts to penetrate the ice pack north of 72° were abandoned, and the ship proceeded westward on 24 August.

Hydrographic sections were more successful in the lighter ice west of longitude 145°. Deployment of ARGOS buoys and helicopter CTD stations continued as weather permitted.

One task of the cruise was the location and recovery of a damaged meteorological research buoy from the drifting remains of the ice camp used for the spring 1985 Arctic

Figure 3. Location of all stations during the Polar Sea cruise in August–September 1985.

Internal Wave Experiment (AIWEX) located near 73°N 151°W . The site was reached at 1600 GMT on 29 August, but fog prevented recovery until 1400 on 30 August. While we were in the area, a 20-min time series of temperature and conductivity was taken at six selected depths to help calibrate a nearby SALARGOS oceanographic buoy.

The Barrow Canyon area was reached on 2 September 1985, and hydrographic sections commenced at 0523. Fifty-one stations were established on five lines, with four lines perpendicular to the coast and one paralleling it. These lines were at the same locations as sections obtained during previous APL studies over the past 15 years, but the stations were more closely spaced. Upon completion of the first Barrow Canyon series, the ship departed for Hanna Shoal near 71°N , 161°W to deploy the last ARGOS buoy.

The next exercise was a series of hydrographic sections perpendicular to the coast east of Pt. Barrow near 149°W to fill in between the earlier lines and to record changes due to the movement of water through the Barrow Canyon during the prior week. Helicopter stations were taken when possible; however, fog interfered.

The Barrow Canyon stations were repeated starting on 12 September at 1232 and finishing on 15 September at 0049. Four of the previous 51 stations were eliminated because of a shortage of time.

Because of deteriorating weather conditions (40-knot winds, snow, and rain), departure of the scientific party from the ship was delayed until 17 September. The scientific party departed from Barrow on the night of 17 September and from Anchorage on 18 September. The scientific equipment was returned to Seattle on the *Polar Sea*, which arrived on 1 October.

Altogether, 150 vertical profiles were made with the Neil Brown CTD unit and 111 with the APL CTD unit. Four APL/PSC ARGOS meteorological buoys were deployed to fill out an existing grid, and the 1985 AIWEX-ARGOS buoy was recovered for analysis of its failure.

III. WEATHER AND POSITION DATA

Weather and position data were provided by the *Polar Sea*. Table I is a copy of the ship's weather records. The position data were obtained from her navigation system, which was updated with NAVSAT fixes every few hours. During the 30 min to 1 h that the ship stopped for each hydrographic station, an average position was obtained and assigned to that station. When both CTD instruments were used, a separate station number was given to each drop even though they were at the same position. The times and positions of all stations are given in Table II.

SHIP'S WEATHER OBSERVATIONS

(PRINT ALL ENTRIES)

TIME ZONE
IS +8 UNIFORMU.S. DEPARTMENT OF COMMERCE
NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION
NATIONAL WEATHER SERVICE

GENERAL INSTRUCTIONS

1. Print all entries using a black ballpoint pen.
2. Complete appropriate blocks on the upper left side.
3. Entries in shaded columns are not to be transmitted by radio.
4. Start new sheet at the beginning of each month.
5. Complete all columns; substitute "/" for elements within a group that are not observed. Groups preceded by a number may be omitted if none of the elements in the group are observed.
6. See NWS Observing Handbook No. 1 for complete observing and coding instructions.

SHIP'S NAME AND SPEED		SEA SURFACE TEMPERATURE		WAVES										ICE ACCRETION		ICE		REMARKS Please enter times of beginning and ending of precipitation of any kind, fog (visibility 1/2 nautical mi. or less), and thun- der; also times of windshifts. Enter details of special or unusual phenomena such as frontal passages, water- spouts, change of water color, slicks, oil, etc.	TRANSMISSION DETAILS Please give call sign of radio station to which message was sent, and time sent GMT	OBSERVER'S INITIALS (PRINT)

SHIP'S WEATHER OBSERVATIONS

(PRINT ALL ENTRIES)

U.S. DEPARTMENT OF COMMERCE
NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION
NATIONAL WEATHER SERVICE

GENERAL INSTRUCTIONS

1. Print all entries using a black ballpoint pen.
2. Complete appropriate blocks on the upper left side.
3. Entries in shaded columns are not to be transmitted by radio.
4. Start new sheet at the beginning of each month.
5. Complete all columns; substitute "/" for elements within a group that are not observed. Groups preceded by a number may be omitted if none of the elements in the group are observed.
6. See NWS Observing Handbook No. 1 for complete observing and coding instructions.

SHIP'S WEATHER OBSERVATIONS

(PRINT ALL ENTRIES)

U.S. DEPARTMENT OF COMMERCE
NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION
NATIONAL WEATHER SERVICE

GENERAL INSTRUCTIONS

1. Print all entries using a black ballpoint pen.
2. Complete appropriate blocks on the upper left side.
3. Entries in shaded columns are not to be transmitted by radio.
4. Start new sheet at the beginning of each month.
5. Complete all columns; substitute "I" for elements within a group that are not observed. Groups preceded by a number may be omitted if none of the elements in the group are observed.
6. See NWS Observing Handbook No. 1 for complete observing and coding instructions.

SHIP'S NAME AND PORT		SEA SURFACE TEMPERATURE	WAVES										ICE ACCRETION		ICE				REMARKS Please enter times of beginning and ending of precipitation of any kind, fog (visibility 1/2 nautical mi. or less), and thunder; also times of windshifts. Enter details of special or unusual phenomena such as frontal passages, water-spouts, change of water color, slicks, oil, etc.	TRANSMISSION DETAILS Please give call sign of radio station to which message was sent, and time sent GMT	OBSERVER'S INITIALS (PRINT)

IV. SATELLITE IMAGERY

A. Ice Coverage

The satellite images obtained from the Geophysical Institute, University of Alaska, before the cruise were extremely helpful, resulting in several modifications to the ship's track to avoid heavy ice.

The NOAA and LANDSAT images in the visible band gave some information on the location of the ice, but unfortunately clouds often obscured the view. The LANDSAT image reproduced in Figure 4 shows a view off Pt. Barrow on 4 August when the ice was close to shore. A NOAA image taken on 20 August (Figure 5) shows the ice has moved northwestward. Notice the ridge of older ice, which appears white in both images. During the 16-day interval between the two photographs, the ridge has moved westward, and the ice floe has broken up near the edge.

In Figure 5, there appears to be a movement of ice toward the coast near Wainwright. As this ice nears the coast, it is swept along in the Alaskan Coastal Current. This recirculation was observed in 1971 and 1972, when occupied ice camps were swept into the coastal current. A view of the ice on 10 September off Harrison Bay is shown in Figure 6. The edge of the pack is made up of large, separated floes intermingled with small fragments.

Figure 7 shows conditions off the coast from Pt. Barrow to Barter Island on 18 September. Even though much of the area is obscured by haze, it can be seen that the ice floes near the edge of the pack are more widely separated.

B. Infrared Temperatures

Some NOAA images in the infrared frequencies were enhanced to obtain details at temperatures of interest. Figure 8 shows a NOAA image for 5 August in which the temperatures from -2 to $+8^{\circ}\text{C}$ have been enhanced so that each degree corresponds to a small shift in the dot density of the gray scale. It is difficult to identify individual temperatures, but the scale varies from white for the ice, which is below -2°C , to black for the open water near shore, which is at about 8°C . The land is warmer than the enhancement region and thus shows as white. The path of the coastal current past Pt. Barrow is clearly shown as a plume that ends in eddies and mixing, with a branch at right angles that follows the edge of the land.

Figure 9 shows a second enhancement for the same data as Figure 8. In this enhancement, each 1° change in temperature is shown by a contrasting shade on the gray scale, but the shades do not necessarily become progressively darker. The figure shows a temperature change from 0°C for open water (white) to 4° (black) and on to warmer temperatures (using white again and gradually darkening shades) up to the coastal current maximum of 6 or 7°C .

Figure 4. Ice conditions off Pt. Barrow on 4 August as seen in a LANDSAT image.

Figure 5. Ice conditions off the coast on 20 August as seen in a NOAA satellite image.

Figure 6. Ice conditions off Harrison Bay on 10 September as seen in a LANDSAT image.

Figure 7. Ice conditions off the coast from Pt. Barrow to Barter Island on 18 September as seen in a NOAA satellite image.

Figure 8. An enhanced NOAA IR image on 5 August that shows by gray scale the transition from white for the ice below -2°C to black at 8°C for the warm open water along the shore.

Figure 9. A NOAA satellite image on 5 August that shows an enhanced IR for $0-4^{\circ}\text{C}$. Beyond the black at 4°C there is another white and some successively darker grays that indicate higher temperatures.

The most valuable enhancement was for 0 to 4°C on 25 August (Figure 10). Both the open water at 0°C and the core of 4°C water off Pt. Barrow show up as black. Between these black areas is a series of 1° increments — shown as medium gray, dark gray, and light gray — representing temperatures of 1, 2, and 3°C. The core of 4°C water off Pt. Barrow is followed by white and light grays, indicating temperatures above 4°C.

The image gives the impression that the warm coastal current continues past Pt. Barrow for about 100 miles before it mixes or disappears beneath the ice (see Figure 16 in next section). Only a small amount turns the corner and follows the coast eastward. This branch may extend to Cape Halkett; the warm areas shown farther east are probably due to warming from sunlight in the shallows. This warm surface water shown in the satellite image is closer to the coast than the ship's CTD stations, and thus the image gives added information on the extent of the intrusion.

The warm plume with a core of about 6°C from the Mackenzie River outflow is plainly visible in the satellite IR images. Judging from the extent of water $>-2^{\circ}\text{C}$ in Figure 8 for 5 August, it affected an area 185 km wide that extended about 130 km seaward. Another enhancement of the Mackenzie River outflow is shown in Figure 11. The temperatures represented are not accurately known, but the pattern is helpful when compared with Figure 8.

Some details of the temperature pattern can be seen in Figure 12, an enhancement for 5 August of the area off the coast from Pt. Hope to Pt. Barrow. Going from coldest to warmest, the temperature gradations begin with black in the open sea, representing $<0^{\circ}\text{C}$, then white, at about 1°C , then to several contrasting grays, and back to black again, representing about 5°C . A second white near Pt. Franklin and along the coast south of Wainwright, representing temperatures $>5^{\circ}\text{C}$, is followed by darker shades representing even higher temperatures off Pt. Hope. There are two bands of clouds, which can be identified over the land and which have to be ignored. The image shows that a large portion of the flow is northward off Pt. Hope in addition to the flow close along the coast toward Pt. Barrow.

Figure 13 shows the same area, with a different enhancement, for 17 August, a day with no cloud interference. The elongated stream past Pt. Barrow indicates how far the warm water is carried before it mixes or encounters the ice. The streamer ends at 149°W , which is inside the reported ice boundary (see Figure 15 in next section). As will be shown in Section XI, this agrees with the extent of the warm coastal current indicated by the oceanographic measurements.

The status of the coastal current on 5 September is shown by the two enhancements in Figure 14. As the northward flow passes Pt. Hope, it appears to divide into two branches, one to the north and the other along the coast. The band along the coast is at 6°C , whereas the large extension to the north is at 5°C .

Figure 10. A NOAA satellite image for 25 August with a 0-4° IR enhancement. Contrasting gray scales were used to show 1° temperature gradations from open water at 0°C to a black core at 4°C and some white and gray for higher temperatures.

Figure 13. Another enhancement for 17 August showing the pattern of the northerly current past Pt. Hope.

Figure 14. Two enhancements for 5 September showing the spread of the coastal current north of Pt. Hope.

V. ICE CONDITIONS

Ice reports were received from Environment Canada, Ice Control, Ottawa, once a day by radio facsimile on the *Polar Sea*. These consisted of a plot of the 2/10 and the 9/10 coverage lines. Although reports were obtained each day, some were faulty and some showed no change. We have selected as representative the coverage charts for 18 and 27 August and 3, 9, and 13 September and plotted the 2/10 and 9/10 lines in Figures 15–19 for the five days. The ice cover near the time of each of the two surveys of the Barrow Canyon area is shown in Figures 20 and 21. The changes during the 27 day period are shown in Figures 22 and 23, in which we have plotted each line for all 5 days on one graph. The ice is receding in both areas where a warm intrusion occurs. Some westerly movement of the ice is evident, which helps to open up large areas west of Pt. Barrow and west of the Mackenzie River. The winds reported by the ship (Section III) do not seem sufficiently easterly to produce this effect. The movement may be more a result of the Beaufort Gyre.

VI. RIVER RUNOFF

Gauging measurements for the Mackenzie River have been obtained from Environment Canada. The 1985 data, however, are available only in preliminary form. A summary of the monthly runoff at a station on the main channel that is reported to represent at least 84% of the Mackenzie River flow is given for the 12 years prior to 1985 in Figure 24. Preliminary data for 1985 indicate that the monthly distribution was typical of the previous 12 years. The annual runoff, with a 12-year average of $282 \text{ km}^3/\text{year}$, is plotted in Figure 25, along with the preliminary value of $293 \text{ km}^3/\text{year}$ reported for 1985. This is a transport of 0.01 Sv compared with 0.6 Sv for the Alaskan Coastal Current northward through Bering Strait. Assuming this runoff was distributed over the area seen on the IR image (or on the surface temperature plot in Figure 60), we calculated the thickness of water added by the river during June–August and during the year. The results are shown in Table III.

A study¹⁴ of the Mackenzie River delta shows average temperatures as follows: May, 0°C ; June, 7°C ; July, 15°C ; August, 14°C ; September, 3°C ; October, 0°C . Since the river water is still cold in May, only the June–August flow would be effective in warming the surface layer. Table III shows that this warm water could be 4–5 m thick, indicating that the Mackenzie River may have an appreciable effect on ice melt some 200 km (108 n.mi.) from the mouth, perhaps farther at times when the discharge pattern is thinner or more elongated.

Figure 24. Monthly totals for Mackenzie River flow, 1973-1984.

Figure 25. Annual Mackenzie River flow for years 1973-1984 as reported by Environment Canada. A preliminary value for 1985 has been added.

Table III. Thickness of layer produced (volume/area).

	3 Mo. Flow	Yearly Flow
Warm area from IR image 185 × 130 km	5.7 m	11.8 m
Warm area from CTD near-surface temperature 220 × 150 km	4.1 m	8.6 m

In making these calculations, other rivers that enter the Beaufort Sea between Pt. Barrow and the Mackenzie have been ignored, since the flow from even the largest of these, the Kuparik River (which has an annual flow of about 1.2 km^3) and the Sagavanirktok River (which has an annual flow of about 1.0 km^3), is small compared with that of the Mackenzie River ($282 \text{ km}^3/\text{year}$).

From the records of river flow and temperature provided by Environment Canada, we compute that the heat added (with respect to the ambient water temperature of -2°C) by the Mackenzie River for the year was 2.4×10^{15} kilocalories. Using the temperature profiles shown in Appendix A, we estimate the heat added to the water column was 3×10^{15} kilocalories — in close agreement. The effect of Mackenzie River runoff on salinity should be several times as great as on temperature, because of the drastic difference in the salinity of fresh and seawater and the greater effective volumes involved (an entire year's flow of fresh water vs 3 mo. of warm water).

A similar calculation for the heat change caused by the Alaskan Coastal Current in and east of the Barrow Canyon gives 6×10^{15} kilocalories. This means that the Mackenzie River, with 1/60 the volume input by the Alaskan Coastal Current through Bering Strait, has nearly as much influence in the Beaufort Sea. This is mainly because only a small portion of the flow through Bering Strait enters the Beaufort Sea via the Barrow Canyon. A secondary reason is that more heat is lost during the longer travel of the coastal current. These comparisons stress the importance of the Mackenzie River to Beaufort Sea oceanography.

VII. TEMPERATURE AND SALINITY MEASUREMENTS

Two CTD systems were operated during the cruise, one by ASL and the other by APL. Each system had its advantages, and the duplication provided added confidence in the results. In this section, we will first describe the instrumentation and its calibration, and then present the data in the form of vertical profiles and temperature-salinity (TS) diagrams.

A. Instrumentation

The CTD unit used by ASL was a Neil Brown system (Model III, Serial No. D1-01-2904-1). The sensors were attached to the end of the cable on the ship's oceanographic winch, and the upper end of the cable was connected to a recording system.

During the cruise, all data were recorded on magnetic media as raw sensor signals in real time. Processing was performed at varying time scales and to varying extents, from immediate plotting of all calculable and directly observable parameters (ASL) to spot checking and limited plotting of some parameters (APL). This was facilitated through use of the ASL Hewlett-Packard 110 portable "lap-top" computer system. This system not only logged data at 5 Hz in real time, but stored the raw data on disk and then calculated and plotted all parameters, using routines stored in RAM, by means of simple commands from the keyboard. This enabled the watch-standers to examine enhanced or modified profiles immediately as well as TS plots and tabular listings. The availability of the system and its flexibility were of unquestionable value both at the time and during subsequent processing.

Post-processing of ASL data was a simple matter of assigning station numbers to all casts and selecting the most appropriate format parameters for compatibility with the APL data.

The CTD system used by APL has been described in a previous report.¹⁵ The system was manufactured at APL and used as a lightweight portable profiler for numerous arctic expeditions. A small hand-powered winch, with a tape recorder mounted in the hub to avoid the need for slip rings, was fastened in place on the deck. The sensor cable was supported on a light boom 2 m forward of the ASL system. The APL cast was usually made immediately after the ASL cast was completed. Occasionally, the APL CTD system was operated from a helicopter which landed on the ice. At the completion of the APL cast, the cassette tape was removed and taken to a dry laboratory, where preliminary plots of the temperature and salinity profiles were produced in half an hour.

Post-processing of APL data consisted of rerecording the data on the cassettes onto nine-track tape, selecting calibration constants, eliminating obvious errors, and plotting vertical profiles and TS diagrams.

B. Calibration

Calibration of the two instrument systems was checked routinely. This was done by taking Nansen bottle samples at depths where properties were stable and determining their salinities with a laboratory salinometer calibrated with standard seawater.

The ASL Neil Brown CTD system was post-calibrated at the Northwest Regional Calibration Center (NRRC) in a continuing program of regular calibrations at that facility. The APL CTD system employed sensors with long calibration histories and known stability; the sensors were calibrated 6 mo. before the cruise and recalibrated 2 mo. afterward at NRRC.

Comparison of both systems with bottle samples, combined with post-calibration, indicated 95% confidence levels of $\pm 0.01^\circ\text{C}$ for temperature, $\pm 0.02\text{‰}$ for salinity, and ± 0.25 m for depth.

C. Vertical Profiles

Vertical profiles of temperature, salinity, sound speed, and density (σ_T) were obtained with both the ASL and APL CTD units. Usually ASL's was employed first and APL's immediately afterward. The ASL system could be operated to a depth of 550 m, whereas the APL unit was limited to 300 m by the cable length. The ASL probe was considered too valuable to risk contacting the bottom. The APL probe was lowered to the bottom routinely and thus obtained additional information on bottom layers.

CTD stations were occupied at intervals along lines perpendicular to the coast as will be discussed in the next section. An example of the plotted profiles is shown in Figure 26. When both units were operated at the same station, the two profiles are plotted on the same page. At the bottom of the page are tabulated values of the parameters at 5 m depth intervals, increased to 10 m intervals at middle depths and 15 m at lower depths. At the top of the plot are indicated the station number, time, and location and the system and platform in use.

Each laboratory had its own method of presenting the profiles. The two sets of profiles should agree except for slight changes with location or time during the half hour between the two casts, when some ship drift may have occurred. At times, only the ASL system was used on board. When a helicopter was used as a platform, only the APL system was employed.

All profiles are presented in Appendix A in the order taken. A separate station number was given to each CTD system when both were used at the same location.

Often when there is a sharp change in temperature there is also one in the other properties. If the temperature and conductivity are not measured for the same water, or

Figure 26. Sample presentation of CTD profile (above) and tabulated data at 5-15 m intervals (below).

equivalent water, the computed salinity, which depends on both temperature and conductivity, will show an erroneous reading followed by a gradual change back to the correct one. Such errors have to be considered before ascribing a decrease in salinity with depth as an indication of instability, which is unlikely but possible if there are differential water movements. Because of this possible equipment error when sudden temperature changes occur, we hesitate to state that any of the observed salinity excursions represent unstable conditions. One exception is station 99, where a 6 m thick layer of water at 6°C was found in water at 2°C. The layer appears to be more dense than water just below it. Readings within and below the layer were numerous and steady; therefore, we think that the change is real, and that this was an unstable condition.

D. TS Diagrams

Temperature-salinity diagrams have been plotted for many of the profiles, for both units. An example is shown in Figure 27. Near-surface variations usually make up about half the diagram and often result in loops and excursions when steep gradients are present. Composite diagrams will be presented in Section X.E, and the region of each water type will be outlined.

TS diagrams for most of the stations are shown in Appendix B. The APL diagrams have two sigma-T lines and are all at the same scale. The ASL diagrams have been expanded to show more detail. Some missing diagrams and missing salinity plots cannot be recovered without considerable delay in publication.

VIII. SECTION PLOTS

Stations along lines either parallel or perpendicular to the coast were combined to form vertical sections of temperature or salinity. The selected lines, as well as the ice cover in each area at the time the stations were occupied, are shown in Figures 28–30.

The first longitudinal section through the Barrow Canyon (section G) did not follow the path of the cold Chukchi Sea bottom water. An alternate for section G (labeled G') has been constructed by using stations with the maximum amount of this cold layer (see Figure 31). In constructing the sections, isotherms and isohalines were drawn to make a smooth and logical variation between stations. The sections are presented in Figures 32–51.

In the temperature sections, two types of water are delineated by shading. The first is water warmer than $+1^{\circ}\text{C}$, which we arbitrarily considered an intrusion, either from the coastal current or from river runoff. The second is water colder than -1.5°C , which includes the bottom water that appears to form in the Chukchi Sea along the coast in the winter and move downward along the bottom of the Barrow Canyon in the spring.^{16,17}

Figure 50. Line R cross sections showing temperature and salinity.

Figure 51. Line S cross sections showing temperature and salinity.

The maximum temperature at each station is shown in Figures 52 and 53. The minimum temperature at each station is shown in Figures 54 and 55.

Stations with a maximum temperature exceeding 1°C are shown in Figure 56. Expanded views of stations with water $>1^{\circ}\text{C}$ in the two Barrow Canyon surveys are shown in Figure 57. Also plotted on each figure is the ice cover near the time of the CTD measurements. The warm water plot can be extended shoreward by using the satellite image for 25 August (Figure 10); of course, this is surface temperature only, as indicated by IR emission. Based on the satellite data, the warm intrusion appears to progress around Pt. Barrow and follow the coast to Cape Halkett.

The extent of the cold bottom layer ($<-1.5^{\circ}\text{C}$) is shown in Figures 58 and 59. Nearly all stations have such cold water. In Section X, we will repeat these figures for lower thresholds.

IX. SURFACE CONDITIONS

The changes in water properties at the surface are a good indicator of water movements if the depth of the surface layer is known. Surface layer conditions can indicate river runoff even if there has been considerable mixing with the existing water.

A. Surface Properties, 1985

The surface temperature readings recorded by the profilers may be inaccurate because of the disturbance created when the ship comes to a stop, although careful ship handling that allows some forward motion at the last minute can result in an undisturbed surface layer. Ignoring fluctuations, we have plotted the first steady surface temperatures for all stations in Figures 60 and 61. The warm coastal current and the Mackenzie River runoff are indicated by temperatures $>1^{\circ}\text{C}$.

Figure 60. Surface layer temperatures ($^{\circ}\text{C}$) from the CTD profiles. For the Barrow Canyon area, see Figure 61.

Figure 61. Surface layer temperatures ($^{\circ}\text{C}$) from the CTD profiles for the two Barrow Canyon surveys.

The surface salinity readings may show a thin layer of low salinity due to melting ice. We consider here only surface layers at least 3 m thick, since this amount of low-salinity water should indicate river runoff. Figure 62 indicates the surface salinity at each station. The low salinities in the eastern portion show the effect of the Mackenzie River. The low values near section M may indicate that other rivers have contributed along the coastline. Figure 63 shows surface salinities for the Barrow Canyon area. The coastal current, which crowds along the coast, has a higher salinity, and this salinity increases for the second survey.

Figure 62. Surface layer salinities (‰) from the CTD profiles. For the Barrow Canyon area, see Figure 63.

Figure 63. Surface layer salinities (‰) from the CTD profiles for the two Barrow Canyon surveys.

B. Other Cruises in Past Years

Data from other cruises were examined, and the surface temperatures and salinities extracted and plotted for comparison with the 1985 data. Plots for the following cruises, by ship name, appear in Appendix C. There are large differences from year to year. Some of this variation may be due to the method of measuring surface temperature and salinity.

Figure	Cruise	Year
C-1	<i>Burton Island</i>	1950
C-2	<i>Burton Island</i>	1951
C-3	<i>Atka</i>	1957
C-4	<i>Staten Island</i>	1959
C-5	<i>Glacier, Natchik</i>	1972 (S only)

C. Satellite IR Patterns

A comparison of the surface temperatures obtained from the CTD profiles (Figures 60 and 61) with those interpreted from satellite IR measurements shows fair agreement. The IR results could represent a much thinner layer, but the agreement shown here indicates that there were no thin temperature layers.

The IR images in Figures 8–10 demonstrate the temperature pattern along the coast. The considerable amounts of warm water between Pt. Barrow and Cape Halkett appear to be related to the coastal current's deposit of warm water in a long plume past Pt. Barrow. The warm coastal water east of Barter Island appears to be related to the Mackenzie River outflow. The warm areas shown along the coast in the satellite images do not extend as far seaward as the closest CTD stations; therefore this warm water was not seen in the CTD profiles.

X. ANALYSIS OF WATER EXCHANGE

Several means are at our disposal for studying and understanding the water movements prior to and during the survey. Previous oceanographic studies^{5,17} of the Barrow Canyon area are helpful in identifying and tracing water types. Some of the changes taking place in the Barrow Canyon area can be analyzed by comparing the two cross sections taken 10 days apart. Interpretation of the surface layers observed by the CTD stations can be augmented by the IR satellite images. The Mackenzie River outflow is observed as a surface layer in the temperature and salinity profiles as well as in the IR images.

A. Atlantic Water

The Atlantic Water is a permanent feature of the western Arctic Ocean; it usually occurs at 200–900 m depth and is marked by $T > -1^{\circ}\text{C}$ and $S > 34\text{‰}$. Measurements in 1976 off the lower end of the Barrow Canyon showed some displacement of the upper traces of this water (which are at -1.5 to -1.0°C as a result of mixing) from 150 m to 190 m due to the movement of low-temperature, high-salinity water down the canyon (discussed in the next paragraph). The other water types discussed here are lighter and tend to remain above the Atlantic Water.

B. Chukchi Bottom Layer

A cold, high-salinity bottom layer was traced from the Chukchi Sea down the Barrow Canyon in previous studies.^{16,17} This water moves slowly down the canyon during the spring; thus we found considerable amounts of it in August, as shown in the temperature sections. This water is being forced seaward by the incoming coastal flow from the south. This year, the Chukchi bottom water was at $T = -1.7^{\circ}\text{C}$ and $S = 32.7\text{‰}$. An outline of this uniform water mass is shown in Figure 64 for the two Barrow Canyon surveys. These figures were obtained from the G' and O longitudinal sections. Transverse section S shows that this is about the extent of the bottom water's travel except possibly more to seaward. Comparisons of transverse sections R and S with sections I and H show this water diminished during the 10-day interval.

A plan view of the extent of the cold bottom layer is shown in Figures 65 and 66 for two thresholds, $T < -1.6^{\circ}\text{C}$ and $T < -1.7^{\circ}\text{C}$. It appears as far east as 149°W longitude. Station 33 at 145°W longitude may also contain a trace of this water at -1.69°C . The appearance of this water at station 33 would extend the eastern boundary, but water this cold is not necessarily Chukchi bottom water. Instead, it may be caused by winter freezing in the adjacent shallows and subsequent drainage of the resulting cold, saline water to lower depths — the same process responsible for the formation of the Chukchi bottom layer.

Figure 64. Chukchi Sea bottom water with constant properties ($T = -1.7^{\circ}\text{C}$, $S = 32.7\text{‰}$) for the two Barrow Canyon surveys.

Figure 65. Extent of the Chukchi bottom water when defined as $T < -1.6^{\circ}\text{C}$. Dashed lines show the ice cover at the times of the CTD profiles, and are a composite of Figures 15–21 which show the change in coverage over the course of the measurements.

Figure 66. Extent of coldest Chukchi bottom water ($T < -1.7^{\circ}\text{C}$).

Similar plots are shown for both surveys of the Barrow Canyon area in Figures 67 and 68. In the plots for $T < -1.7^{\circ}\text{C}$, the core of the drainage lies along the trough of the canyon. A comparison of the two surveys shows this water has moved down the canyon during the 10-day interval. Such flow may be intermittent.

Figure 67. Extent of Chukchi bottom water ($T < -1.6^{\circ}\text{C}$) for the two Barrow Canyon surveys.

Figure 68. Extent of the coldest Chukchi bottom water ($T < -1.7^{\circ}\text{C}$) for the two Barrow Canyon surveys.

C. Coastal Flow from the South

The Alaskan Coastal Current has been studied extensively.^{4,6,7} Aagaard¹⁸ and Mountain et al.⁵ refer to two main components: Bering Sea water and Alaskan coastal water. Whereas Bering Sea water comes from well below the surface in the Bering Sea, the coastal water is near-surface water that has been warmed in shallow areas both north and south of Bering Strait, especially in Norton Sound and Kotzebue Sound, and has subsequently been carried northward and along the coast past Pt. Hope. Two distinct examples of coastal water are apparent at stations 48 and 190, the southernmost stations that were occupied. Each appears as a uniform water mass, with a sharp gradient between (see Figure 69). As these waters move northward, they crowd the coast because of the Coriolis force and displace the existing water seaward, as shown in Figures 40–43 and 48–51. Figures 41 and 51 show that some of the incoming Bering Sea water has sufficient salinity (and therefore density) to intrude as deep as 140 m, thus merging into Atlantic Water of the same temperature and salinity.

Figure 69.
Distinct layers of water entering the survey area along the coast from the southwest.

The horizontal extent of this warm coastal water is shown in Figure 56. Close examination of the profiles shows that the layer of coastal water is observable as far east as 148°W longitude. Additional information on the presence of Alaskan coastal water along the coast east of Pt. Barrow can be obtained from satellite imagery (Figures 8–10). Considerable surface warmth from the coastal current appears as far east as Cape Halkett. The warm water farther east is probably caused by solar warming in the shallows.

Observations of the warm layers farther to the north in prior years indicate that the warm water deposited in the Beaufort Sea spreads out over many miles before it is cooled or mixed thoroughly. Distinct layers of 0°C water were observed¹¹ in October 1984 at depths of 30–40 m at 73°20'N latitude. A short time later these layers disappeared, giving the impression that the observations were made near their northerly limit. In 1980, 40-m-thick layers of 2°C water were found at 72°04'N, 155°W. The maximum temperature of the layer remained above 0°C as the survey progressed northward to 72°50' latitude.

The remnant of this warm water has become a permanent feature of the western Arctic and has been discussed by Coachman and Barnes⁷ who called it a "shallow temperature maximum" layer. It is described as being at 75–100 m depth, which could be the remnant of the layers observed by APL after the shallower portion has been cooled from above.

The presence of the coastal current at 148°W longitude is not surprising in light of the calculation by Mountain et al.⁵ that the momentum of the current passing Pt. Barrow would carry it to 140°W longitude.

There have been observations of ice apparently being drawn into the coastal current north of Wainwright. This might be a partial recirculation of the coastal current after it passes Pt. Barrow, first northward, then westward in the fringe of the Beaufort Gyre, and finally returning to the coastal current near Wainwright. This agrees with a barotropic model formulated by Budgell.¹⁹

D. Mackenzie River Water

Mackenzie River water can be detected by its higher temperature and its low salinity. Figure 52 shows a large area with CTD maximum temperatures greater than 0°C. This area extends from 136°W to 141°W. Figure 60 shows surface temperatures to a greater accuracy with the same result.

Additional information on the distribution of the warm river water can be seen in the satellite IR images, Figures 8, 10, and 11. In Figures 8 and 11 for 5 August, the outflow occupies a blunt, broad area off the wide river delta. There is no indication in section B (Figure 33) of the warm area shown farther out, possibly because section B was taken 2 weeks later or because the warm water was beneath the ice cover as shown in Figure 60. Later, on 25 August, as shown in Figure 10, a warm plume appears to extend almost as far west as Barter Island. The core temperature appears as high as it is off Pt. Barrow, 4–5°C.

Figure 63 shows low surface salinities over a slightly broader area, 135–141°W longitude.

The existence of warm temperatures about 150 km off the coast north of the Mackenzie River, and low salinities at about 220 km, indicates the presence of river water. This warm water would be expected to cause deterioration in the ice. At times, easterly winds move the ice eastward from Banks Island, and the resulting open area allows the spread of river water northward. Penetration into the pack then causes "rotting" of the ice. Such deterioration was observed in the fall of 1984,¹¹ when the large floe that was initially selected as a camp site broke into several pieces before we reached it. The search was then redirected to the northwest, where more solid floes were found.

E. Water Types Seen in the TS Diagrams

Individual TS diagrams for many of the profiles are shown in Appendix B. Composite diagrams for several stations in the Barrow Canyon area, the central region, and the eastern portion are shown in Figures 70–73. Heavy concentrations of dots in the plots indicate the presence of some of the water masses discussed above. For ease of comparison, Figure 74 shows where the various water types would be positioned on the TS

Figure 70. Composite TS diagram for the first Barrow Canyon survey, stations 47–147 (APL stations only).

Figure 73. Composite TS diagram for the eastern portion of the survey area, stations 1, 11, 12, 24-32, 34, and 35.

Figure 74. The outline of various water types on the TS diagram.

diagram before they mix with other types. Atlantic Water, for example, would occupy a narrow band at the right. The Chukchi bottom layer is the dark area in Figures 70 and 71 near $T = -1.7^{\circ}\text{C}$ and $S = 32.7\text{‰}$. This is not the same water as in Figures 72 and 73, as evidenced by the fact that the plot extends below (to a lower temperature than) the data in those figures.

The warm ($>1^{\circ}\text{C}$) water brought northward by the Alaskan Coastal Current from the shallows of Norton and Kotzebue sounds is not easily separable from the denser Bering Sea water described by Mountain et al.,⁵ but their choice of $31.5\text{--}32.5\text{‰}$ for Bering Sea water seems appropriate. Figure 72 shows the trace of warm water at station 159 which appears to be the eastern extreme of the $+1.0^{\circ}\text{C}$ water of the warm intrusion. Its position outside the water types designated in Figure 74 is due to cooling as the result of mixing with the existing winter water.

XI. CONCLUSIONS

We have observed the influence of three major inputs of water into the southern Beaufort Sea: a drainage of bottom water from the Chukchi Sea down the Barrow Canyon; the Alaskan Coastal Current, primarily from the Bering Sea; and the runoff from the Mackenzie River.

A. Chukchi Bottom Water

Prior measurements in the spring have shown a bottom layer of water with a slightly higher salinity than typical Chukchi Sea winter water. This water has been observed to flow down the Barrow Canyon during the spring and summer. The September 1985 measurements show a uniform mass of what appears to be this bottom water (-1.7°C , 32.7‰) at about 100 m depth which has slowly migrated down the Barrow Canyon and come to rest above the layer of Atlantic Water present in the Arctic Ocean. This Chukchi bottom water is observed as far east as 149°W longitude. Along the shoreward side of the canyon, it is being displaced by the densest portion of the coastal current.

B. Alaskan Coastal Current

The Alaskan Coastal Current originates in the Bering Sea and passes northward through Bering Strait. In the summer, it entrains the warmed waters of Norton Sound and Kotzebue Sound. Passing Pt. Hope, the warm water spreads generally northward, but there is a persistent branch to the right along the coast to Pt. Barrow. The August–September 1985 measurements show the warm intrusion closely following the coast and penetrating to a depth of 140 m in the Barrow Canyon. Satellite images show that, when the surface waters of the intrusion pass Pt. Barrow, they continue in an easterly direction for 100 km before mixing with the existing waters. Our CTD profiles in the area in late August 1985 show evidence of the intrusion as far east as 148°W longitude. Eventually the warm mass collapses into thin layers which have been observed (in 1984) as far north as $73^{\circ}20'\text{N}$ latitude. Satellite images show that when the waters pass Pt. Barrow a warm surface layer also spreads along the coast as far east as Cape Halkett.

C. Mackenzie River Outflow

The influence of the Mackenzie River was observed in the surface temperatures 150 km off the coast and in surface salinities 220 km off the coast. Its extent depends somewhat on the location of the ice pack, which tends to block the runoff's northward movement. In August–September 1985, the river water extended from 136 to 141°W longitude.

Based on measurements of the river's flow and temperature at gauging stations, we calculate that the annual heat input by the Mackenzie River into the Beaufort Sea, above the usual sea temperature, is 2.4×10^{15} kilogram calories. With its effect on salinity being greater than its effect on temperature, the Mackenzie River outflow influences Beaufort Sea oceanography nearly as much as the Alaskan Coastal Current.

APPENDIX B

TS Diagrams

This appendix contains temperature-salinity diagrams constructed from CTD profiles taken by the Applied Physics Laboratory (APL) and the Arctic Submarine Laboratory (ASL) from 17 August to 20 September 1985. See Table II for list of stations.

APPENDIX C

Surface Conditions in Prior Years

This appendix contains surface temperature and salinity plots for several earlier cruises.

Figure C-1A. Burton Island cruise, July - September 1950, surface temperatures ($^{\circ}\text{C}$).

Figure C-1B. Burton Island cruise, July - September 1950, surface salinities (‰).

Figure C-2A. Burton Island cruise, August - September 1951, surface temperatures ($^{\circ}\text{C}$).

Figure C-2B. Burton Island cruise, August - September 1951, surface salinities (‰).

Figure C-3A. Atka cruise August 1957, surface temperatures ($^{\circ}\text{C}$).

Figure C-4A. Staten Island cruise, August - September 1959, surface temperatures (°C).

Figure C-5. Glacier and Natchik cruises, August - September 1972, surface salinities (‰).

20. ABSTRACT (Continue on reverse side if necessary and identify by block number) An oceanographic cruise along the north coast of Alaska and Canada in August and September 1985 reveals evidence of how the Alaskan Coastal Current from the southwest and the Mackenzie River outflow in the eastern portion influence oceanographic conditions in the Beaufort Sea. The coastal current crowds the shore and at depth displaces some of the cold, saline bottom water that drains from the Chukchi Sea through the Barrow Canyon in the spring. The eastward extent of the coastal current (cont.)
