19. ABSTRACT (Continue on reverse if necessary and identify by block number) 1988 Survey of Computer Integrated Manufacturing (CIM) equipment updates AMC CIM equipment data in all funding categories for FY80-88 and planning years FY89-92. Report data synopsized to reflect AMC accomplishments during the FY80-88 period and is broken down to show equipment/investment data for nine AMC Major Subordinate Commands. Report coverage lists 745 separate systems with more than 800 applications eg., Computer Aided Design/Engineering/Manufacture (CAD/CAE/CAM) and total acquisition value of 428.8 million dollars. Report assumes investment baseline of 39 million dollars as of FY79 with growth to current FY88 amount of 428.8 and planned growth during FY89-92 of another 20 million for a FY92 total of approximately 450 million dollars. Reported systems include all CIM equipment categories and "stand-alone" Computer Numeric Control (CNC) machines, the preponderance of which are planned for conversion/upgrade to Distributed Numeric Control.(DNC). EXECUTIVE SUMMARY

This 1988 survey of U.S. Army Materiel Command (AMC) owned computer integrated manufacturing (CIM) equipment was initiated to update AMC CIM equipment data in all funding categories for the Fiscal Years 1980 through 1988 and to report on planned acquisitions for Fiscal Years 1989 through 1992. An analysis of available historical data for AMC Manufacturing Methods Technology (MMT) programs up through Fiscal Year 1979 indicated investments of just under 39 million dollars. The 39 million dollar amount was established as the baseline for this survey.

The data and supporting narrative information used to compile this report were solicited from more than 85 AMC activities which were selected to participate as either possible or probable owners of CIM equipment. Most of these activities are part of the nine Major Subordinate Commands (MSCs) which have as one of their primary missions, the responsibility for the acquisition of Army materiel and selected types of materiel for joint service use. Of these nine MSCs, the Armament, Munitions, and Chemical Command (AMCCOM), headquartered at Rock Island, Illinois, reported the largest investment in CIM equipment, approximately 268.5 million dollars. The second largest report of CIM equipment investment (78.8 million dollars) was provided by the Depot Systems Command (DESCOM), headquartered in Chambersburg, Pennsylvania. These two major dollar investments primarily reflect the AMCCOM mission to operate Army arsenals and ammunition plants and the DESCOM mission for all AMC depot facilities.

The total reported investment during the period of FY80 to FY88 has grown from the FY79 39 million dollar investment baseline to approximately 428.8 million dollars today, an eleven fold increase for the nine years. Planned investments for the FY89-92 timeframe are projected just under 20 million dollars, which will bring the AMC owned CIM equipment investment up to nearly 450 million dollars.

Currently, AMC activities report the 450 million dollar figure spread across 745 different CIM equipment systems, used for more than 800 different CIM related functions. Approximately 165 of these 745 systems are Computer Numeric Control (CNC) machines, normally considered as "stand alone" systems, not part of CIM architecture. These CNC machines are, however, included in this survey because an overwhelming number of respondents indicated that high priority has been given to procurement and installation of Distributed Numeric Control (DNC) systems for these CNC machines, which, when implemented, will provide interactive CIM network control.

ACKNOWLEDGMENT

The authors wish to express their thanks to all the engineering, equipment and program management members of the AMC community who contributed their time and talents to acquire the data needed for this survey. Particular appreciation is due for the extraordinary effort at Watervliet Arsenal to provide comprehensive CIM equipment data, the effort at the Production Base Modernization Agency for augmenting data from Army arsenals and ammunition plants, and the effort at DESCOM for coordinating the data collection efforts at Army depot activities.

DEFINITIONS

Automated Materials Handling (AMH) Controls

AMH controls can be defined as the use of computer systems to store and automatically adjust inventory levels and material location data and; to control the movements of materials handling equipment from receiving areas to storage locations; and from storage locations to delivery points or shipping areas. The link between computer integrated manufacturing and AMH controls for warehousing is in the receipt and processing of demand data for material in storage to be pulled from stock and moved on computer command to one or more delivery points in the manufacturing area; and the extraction of completed or partially completed components and finished products to storage until required for product assembly or additional manufacturing steps or; to a shipping area for movement to another geographical location for additional manufacturing or for integration into a larger assemblage which becomes the final report.

Automated Materials Handling (AMH) Equipment

AMH equipment replaces or reduces human labor normally required to transport, store, retrieve, record and manipulate material throughout manufacturing and warehouse areas. Most common AMH equipment includes automated guided vehicles (AGVs) and conveyor systems, which transfer materials between workstations and feed the assembly and packaging processes. Automated storage and retrieval systems (ASRS) are high-density rack storage systems with rail running vehicles that serve the rack structure for automated loading and unloading. The ASRS can be computer-controlled to interface with robots, AGVs and conveyor systems.

Computer Aided Design (CAD)

CAD can be defined as the use of computer systems to assist in the creation, modification, analysis, or optimization of a design. The computer systems consist of hardware and software to perform the specialized design functions required by the particular user firm. The CAD hardware typically includes the computer, one or more graphics display terminals, keyboards, and other peripheral equipment. The CAD software consists of the computer programs to implement computer graphics on the system plus application programs to facilitate the engineering functions.

Computer Aided Design/Computer Aided Manufacture (CAD/CAM)

See Computer Aided Design (CAD) and Computer Aided Manufacture (CAM). CAD/CAM can be defined as the integration of of digital computer systems to achieve automation from a product's design through it's manufacture.

Computer Aided Engineering (CAE)

CAE is the analysis of a design drawn from a CAD system. It is used to check for errors and optimize manufacturability, performance and economy of the design. CAE analyzes the functional characteristics of a part, product or system under design, and simulates performance under various conditions. CAE can be used to determine section properties, moments of inertia, shear and bending movements, dimensions and center of gravity, as well as precisely determined loads, vibration, noise and service life cycle early in the design cycle so that components can be optimized to meet those criteria.

Computer Aided Inspection (CAI)

Computer-Aided Inspection (CAI) and Computer-Aided Testing (CAT) are subsets of Computer Assisted Quality control (CAQC). Whereas these activities have traditionally been performed manually (with the help of gages, measuring devices, and testing apparatus), CAI and CAT are performed automatically using the latest computer and sensor technology. Computer-assisted inspection and testing methods form only part, certainly a major part, of computer-aided quality control.

Computer Aided Manufacture (CAM)

CAM can be defined as the use of computer systems to plan, manage, and control the operations of a manufacturing plant through either direct or indirect computer interface with the plant's production resources. As indicated by the definition, the applications of computer-aided manufacturing fall into two broad categories:

- o Computer monitoring and control. These are the direct applications in which the computer is connected directly to the manufacturing process for the purpose of monitoring or controlling the process.
 - o Manufacturing and support applications. These are the indirect applications in which the computer is used in support of the production operations in the plant, but there is no direct interface between the computer and the manufacturing process.
-

Computer Assisted Quality Control (CAQC)

CAQC is the computer programming and automated database with the primary functions of maintaining and reporting on all aspects of quality control in the manufacturing environment. The database normally contains all performance parameters an item must meet before, during and at the end of manufacture. The CAQC functions include the collection of data from all automated sources of manufacturing such as computer aided inspection and test devices. These data are processed to provide statistical reports of quality control measurements,

to identify actual and potential degradations of quality and to transmit corrective action instructions. CAQC also is a component of and interacts with CIM.

Computer Aided Robot (CAR)

A robot is a programmable, multi-function manipulator designed to move material, parts, tools, or special devices through variable programmed motions for the performance of a variety of tasks. A CAR for industrial applications is a general-purpose, programmable machine which can possess certain anthropomorphic characteristics, typically, its arm. This arm, together with the robot's capacity to be programmed, makes it suitable for repetitive production tasks, e.g., machine loading, spot welding, spray painting and assembly.

Computer Aided Testing (CAT)

See CAI-computer Aided Inspection

Computer Integrated Manufacture (CIM)

CIM is usually referred to as the total integration of design and manufacturing processes into one fully computer controlled and supervised process. CIM can be described as an interactive database management system serving four major functional areas; 1) Business Management Operations, 2) Design and Manufacturing Engineering, 3) Manufacturing, and 4) Plant-Wide Auxiliary Functions.

CIM- Architecture (CIM-A)

CIM-A can be defined as the computer integrated manufacturing architectural framework or structure that determines how the CIM system is constructed. CIM-A is normally developed through the processes of 1) identification of existing facilities, manufacturing capabilities and supporting resources; 2) the determination of the interrelationships between these capabilities; 3) the design of modules and interfaces among modules to support manufacturing processes and; 4) the implementation of architectural design plans for computer integrated manufacturing operation.

Computer Numeric Control (CNC)

CNC is a numerical control system utilizing a dedicated small microcomputer with a reprogrammable memory to store program data and perform some or all of the basic numerical control functions.

Direct Numerical Control (Direct NC)

Direct NC is the direct interactive connection and real time control of a number of machines by a single computer. The traditional tape reader is bypassed - normally removed - with part programming information transmitted directly to the machines from the computer memory. The computer and software programming are designed to transmit instructions to one or more machines on demand and; receive and process data from the machines.

Distributed Numerical Control (DNC)

The term DNC is now commonly used to refer to Distributed vs Direct numerical control systems. DNC can be defined in part as combined Direct NC/CNC systems. DNC systems provide direct interactive real time programming and data collection to and from microprocessors which provide direct control to machines. The microprocessors replace the traditional tape readers and offer much greater reliability. DNC systems offer much greater flexibility permitting totally different programming instructions to be generated and loaded in individual machine microprocess or control units. DNC systems provide an additional advantage of redundancy in the event of host computer failure or in the event of microprocessor failure at one or more machine locations operating on the same series of programming instructions.

Manufacturing Resource Planning (MRP)

MRP is a method for the effective planning of all the resources of a manufacturing company. It connects the complete set of functional subsystems found in most large business enterprises, including Business Planning, Production Planning, Master Production Scheduling, Material Requirements Planning, Capacity Requirements Planning and associated modules. Hence, it is often referred to as a "closed-loop" manufacturing system. The output from MRP is integrated with various financial reports, business plans, inventory and budget projections to enhance the effectiveness and analytical scope of the manufacturing management process.

SECTION 1.0

SECTION 1.0

INTRODUCTION

1.1 GENERAL:

The 1988 survey of the Army Materiel Command's (AMC) computer integrated manufacturing (CIM) equipment provides a summary of computer systems and computer controlled machining and chemical compound processing equipment which support the production of AMC managed weapons systems and other military materiel.

This survey includes all AMC CIM equipment acquired during the first eight years of the 1980s. The survey reflects the accomplishments of AMC through nine Major Subordinate Commands (MSCs) during these years. In the case of the Armament, Munitions and Chemical Command (AMCCOM), separate presentations show accomplishments at arsenals and ammunition plants.

1.2 BACKGROUND:

During the late 1950s and early 1960s, AMC began to acquire numerically controlled production equipment. The earliest recipients were the Arsenals. Army research and development (R&D) laboratories also obtained numerically controlled devices to study and perfect producibility design planning and manufacture demonstration models of future weapons systems. The introduction of robotics followed quickly, primarily in Army ammunition plants and depots. These robots were employed for materials handling, and performing repetitive and potentially hazardous operations such as the handling of explosive materiel, paint spraying, and welding of heavy vehicular equipment. In 1975, computerization of numerically controlled machinery started at Army arsenals engaged in the limited production of small caliber ammunition.

During the late 1970s and early 1980s computer aided manufacture (CAM), computer aided inspection (CAI) and computer aided testing (CAT) were introduced with the advent of the large scale ammunition production base modernization program. AMC's R&D laboratories began to acquire and employ the advanced technology and superiority offered by computer aided design (CAD) and computer aided engineering (CAE) devices. The overall cost of these ventures through 1979 is speculative; however, approximately \$38,566,000 of the total cost was financed by the Manufacturing Methods and Technology (MM&T) Program.

The preponderance of these computer aided devices were employed as stand-alone systems with little or no capability of interacting with one another. They did, however, serve to demonstrate that the potential advantages of improved productivity, safety and the elimination of repetitive labor intensive operations (to name a few), were clearly achievable. Yet to be solved were problems of computer hardware, firmware and software incompatibility. There was, and still is, a proliferation of systems in use operated by software, ideal for specialized purposes, but much less so for interactive communication with other special purpose systems. Part of the solution was to design systems and software according to evolving standards which in the 1960s and 70s were virtually nonexistent. Fortunately, among the proliferation of offerings, improved hardware and new software emerged which provided a capability for stand-alone operations to interact with one another. The next and logical step was to design manufacturing cells, groupings of

machines with similar functions, which could be controlled from a central computer source. Improvements to these operations led to the successful implementation of the second generation of centrally controlled manufacturing cells consisting of a series of different machines to manufacture a product or component of a larger product assemblage. Manufacturing cells have matured to the point that a physical grouping of machine tools and robots can be organized to produce a family of parts. This is now viewed as conventional automation. Computer control systems developed for these cells are now capable of receiving orders from an operator terminal, determine resources needed, schedule, coordinate and monitor individual workstations.

Manufacturing technology has now advanced sufficiently to permit the control and operation of a group of machines as flexible manufacturing systems (FMS). This FMS concept permits relatively rapid changes in shapes and sizes of generally similar type parts. The next (and perhaps most important) step for manufacturing is to design a fully automated manufacturing environment in which one or more computer systems can control all of the managerial, manufacturing and other supporting operations in both a centralized and flexible manner. This next step is computer integrated manufacturing. The CIM concept is the integration of design, engineering and manufacturing systems with traditional data processing systems serving managerial functions. This degree of integration produces the totally automated factory in which all processes are tied together by one or more common databases.

1.3 OBJECTIVE:

The principal objective of this survey was to report on all funding categories of AMC owned CIM systems and components comprising key elements of interactive CIM operations which are part of manufacturing or production facilities. The period covered by this survey is from the beginning of Fiscal Year (FY) 1980 through FY 1988. Figure 1-1 is an example of a manufacturing operation in which all elements of computer integrated equipment addressed in this report are shown. These elements are all between Point "A" and Point "B" on the diagram. The legend in the lower right corner of the chart defines each element.

The secondary objectives were to update available production equipment project data, (actual or planned) prior to FY80; identify projects which were rescheduled, cancelled or phased out; and, to report on approved plans for the future acquisition of CIM systems through FY92. Other objectives included the summarization of AMC accomplishments; compilation of the overall dollar value of investments in computer aided production technology and, break-outs of these data for AMC major subordinate commands, arsenals, ammunition plants and separate activities reporting directly to AMC.

CIM elements consist of computer assisted devices and equipment in the areas of design, engineering, manufacturing resource planning, control of quality standards, and incoming and outgoing materials handling equipment directly supporting production operations. CIM elements also include computer controlled robotic systems, in-process and post manufacture inspection and test equipment, and end of assembly area or production line packaging and shipping operations. Included as part of the principal objective were all items of computer assisted equipment normally found on the manufacturing floor or in direct support of production, regardless of actual location.

COMPUTER INTEGRATED MANUFACTURING

Figure 1-1

This survey also includes computer numerically controlled machinery, normally considered as "stand alone" equipment and not part of a true CIM network operation. Planning, however, (most notably at AMC arsenals and depots) is complete or underway, and in some instances actual conversions of equipment controls have started to convert computer numeric control (CNC) machines utilizing tape drive units to micro processors for machine controlling. The newer generation microprocessor controls permit machinery to be networked as part of distributed numeric control (DNC) systems and from there, inclusion in a CIM network. In every instance when queried, respondents to this survey indicated their installations are committed to DNC technology citing greatly improved reliability of machine control operation, elimination of human intervention to load machine control units (specifically the now outdated paper and mylar tape drive units), and the real time interactive exchange of control and performance data between machines, DNC stations and CIM mainframe computer terminals. With these CNC conversions planned or underway, this type of equipment is included in this survey. The inventory at Appendix 3 lists all components by equipment classification to show which of these equipment items are still operated as CNC machines.

1.4 METHODOLOGY:

The methodology employed to acquire suitable data for analysis was to identify documentation prepared over the past several years which described computer aided production related accomplishments at AMC installations.

Computer aided assets to be included in the 1988 survey were identified as all AMC owned CIM devices "normally found on the manufacturing floor." All categories of funding were to be included. This category of CIM was further defined as any computer aided device which directly supported manufacturing, regardless of location. Not included were the purely managerial functions supported by computer systems which do not directly control manufacturing operations.

A series of system definitions were developed or extracted from engineering publications to define the specific categories of CIM to be included in the survey. A simplified schematic depicting the application of all CIM categories in a manufacturing environment was developed. The definitions, schematic, extracts of available data and a detailed questionnaire were provided to the AMC installation points of contact for their use during the data collection process.

Responses to these requests for CIM data were analyzed to determine applicability to the 1988 survey. These responses constituted the initial data base of inventory, funding and CIM application information. The data, grouped by AMC Major Subordinate Command (MSC) with further sub-grouping for Army Arsenals, Army Ammunition Plants and other selected installations were transposed to an inventory matrix for further analysis. This inventory matrix constituted the basis for the primary database of CIM information. From this data base listing, AMC and MSC summary charts and graphics were developed to list and illustrate CIM investments during the past eight years and planned investments up to FY92. In addition, these lists and graphics were designed to consolidate the information provided in the responses from the AMC installations into quantitative displays of CIM categories.

The inventory data, supporting lists and graphics constitute the enhanced baseline from which the narrative portions of this 1988 survey were developed.

SECTION 2.0

SECTION 2.0

AMC COMPUTER INTEGRATED MANUFACTURING (CIM) EQUIPMENT DISCUSSIONS

2.1 TOTAL AMC CIM EQUIPMENT INVENTORY SUMMARY FY80-FY88:

AMC (with installations and offices in 195 locations) is organized into the headquarters located in Alexandria, Virginia, 12 MSCs and 90 Separate Reporting Activities (SRAs), and liaison and logistic assistance offices throughout the United States, Europe and the Far East. Virtually all AMC owned computer assisted manufacturing and production equipment reported in this survey is at AMC installations assigned to nine of the twelve MSCs as shown in Figure 2-1 which are responsible for a total of 105 installations. Responsibility for these installations is not evenly distributed between the MSCs with AMCCOM controlling 38 installations primarily arsenals and ammunition plants, and Depot Support Command (DESCOM) controlling 22 depots.

Figure 2-1

The data accumulated through the process described in the methodology was formatted as shown at the Appendices, pages A3-1 through A3-59. These

inventory formats contain a brief description of each CIM component, its acquisition date and cost, as well as a summarization of these data for each reporting installation. Some inventory data was not provided; therefore some systems lack vendor source identification, application or precise function data, such as computer aided design, manufacture, inspection or test. These systems, pertain to AMCCOM acquisitions, primarily those supporting Army Ammunition Plant (AAP) activities.

Figures 2-2 through 2-4 depict CIM component growth, investment and distribution for Fiscal Years 1980 - 1992. CIM component investment and quantity information (shown in the figures and tables summarizing the data received from AMC installations that participated in this survey) was extracted from the data and information listed in the inventory at Appendix 3, which shows all reported categories of utilization. Many of these reported items serve a dual or triple purpose. Examples of this which appear in the inventory are CAD/CAM for dual purpose use and CAD/CAE/CAM for triple applications. In those instances of dual and triple purpose use, the reported acquisition value of these multi-purpose systems was equally divided by 2 or 3 (as applicable) to indicate shared application. As an example, equipment with an acquisition value of \$312,600.00 reported as CAD/CAE/CAM system appears in the summary figures and charts as a CAD, a CAE and a CAM to reflect the shared application. Dollar amounts for a system such as this are divided to more closely reflect the purpose of investment. The \$312,600.00 example of a total acquisition value for a triple purpose system would be considered as an investment of \$104,200.00 for inclusion in each of the three categories of CAD, CAE and CAM. The total value of investments shown in the summary figures and tables for each of the nine AMC major subordinate commands is the same as shown in the inventory. In one instance, in Figure 2-4, the actual number of reported systems (745) is shown. The total number of system applications is, however, approximately 801, which was the number used to develop the figure. In this manner, a more accurate percentage of application and capability can be displayed.

Figure 2-2 shows the overall CIM investment growth for AMC. The dollar threshold is approximately \$486,000,000 which includes approximately \$39,000,000.00 as of the end of FY79. The growth curve extends through the end of FY92 with planned acquisitions of an additional \$19,988,400.00

Figure 2-2

Figures 2-3 and 2-4 show CAM systems as the largest dollar investment component category (47 percent) with 38 percent of the reported inventory for these systems. This can be attributed to the fact that many installations reported the combined cost of the computer equipment along with the associated machine tool equipment, particularly in those instances where advanced technology includes imbedded computer aided devices. Conversely, the cost of the balance of the CIM components in many cases reflects only the stand alone computer and peripheral equipment investment.

Figure 2-3

Figure 2-4

2.2 INVENTORY BY MAJOR SUBORDINATE COMMANDS:

AMCCOM has the largest CIM investment (\$268,473,700.00), followed by DESCOM with \$78,774,000.00; Communications-Electronics Command (CECOM) with \$28,496,000.00; the Aviation Systems Command (AVSCOM) with \$24,813,800.00 and; Tank Automotive Command (TACOM) with \$15,793,500.00. The balance of the MSCs trailed with smaller investments. With one exception, all reported CIM equipment is located at AMC installations. AVSCOM submitted CIM investment data for the Lycoming Army Engine Plant, Stratford, CT.

AMCCOM, having the largest number of reporting installations (26 Army Ammunition Plants, four production oriented Arsenals and other activities such as the Armament Research, Development and Engineering Center (ARDEC) and the Chemical Research, Development and Engineering Center (CRDEC)) reported the preponderance of AMC owned CIM equipment. Troop Support Command (TROSCOM), with approximately 90 percent of its annual program directed at the small business industry for general purpose Army materiel, reported the smallest investment. Laboratory Command (LABCOM), while primarily engaged in research and development activities, does maintain a small number of production oriented CAD/CAE systems and CNC machines for small batch production quantities, as well as small job shop functions.

2.3 CIM COMPONENT INVESTMENT APPLICATION AND BREAK OUT:

The data in Figure 2-5 represents a breakout by MSC of the CIM component dollar investment growth. The remaining Tables in Section 2 display CIM investments by various subordinate commands which replied to the information requested by the IEA call letters of 6 July 1987 and 20 August 1987.

The accumulated inventory data was transcribed into a summary chart (Figure 2-5) and Tables 2-1 through 2-15. Figure 2-5 on page 2-6 shows the FY80-88 CIM equipment growth at nine AMC subordinate commands. As can be seen, AMCCOM has the preponderance of CIM investment. Tables 2-1 through 2-15 on pages 2-7 through 2-16 depict the total AMC owned CIM inventory for the FY80-FY88 time frame. These 15 tables also reflect planned acquisitions for the FY80-FY92 time frame, with the exception of Tables 2-2 and 2-3 which reflect actual CIM component and application data for FY80 through FY88. The addition of planning year information in these two tables would be speculative at best.

The total reported accumulated investment over the eight year period was \$428,816,300.00. This is shown on Table 2-1 along with an AMC Major Subordinate Command (MSC) breakout of this total investment. The summarized data listed in Table 2-2 reflects the investment for 745 CIM component systems and is also listed by AMC MSC. Table 2-3 shows a total of 801 equipment applications as many systems have two or three applications. Equipment classifications including multiple classifications are listed for each reported equipment item or system in the inventory list at Appendix 3.

2.4 DESCOM, ASRS, MAJOR DISTRIBUTION CENTERS:

This inventory survey placed primary emphasis on gathering data for all AMC owned CIM equipment associated with production of military products, including the automated control of incoming raw material, components and subassemblies through the manufacturing and packaging functions prior to release of finished

items to supply operations. It did not focus on the AMC owned computer aided equipment in the automatic storage and retrieval systems (ASRS) functions at the distribution centers (major supply depots).

Along with the AMC multi-million dollar investment program to acquire CIM systems, a multi-year program is underway to construct and fully automate the supply operations at the Sharpe, Red River and New Cumberland Army Area Oriented Distribution (AOD) Centers with modern materials handling technology. At Sharpe, building construction is well underway for a new AOD center serving the Western United States and the Pacific region. Construction has started at New Cumberland for the new 40 acre Eastern AOD center serving the Eastern United States, Europe and the Near East. Construction of the new AOD center at Red River is currently planned for the second half of FY89 serving the Central United States the Caribbean region, Central and South America. The ultimate objective is to provide fully automated storage and retrieval systems in the three major supply distribution center depots by the year 2000.
