ABSTRACT

Inexpensive, three-dimensional vehicle simulators are important visualization tools that can enhance training and serve as low-cost platforms for testing mobility expert system algorithms. The moving vehicle simulator is an interactive, real-time system that displays a dynamic, three-dimensional, out-the-window view of the terrain from any vehicle. The simulator has two modes of operation: stand-alone or networked. The networked mode facilitates a missile/target war gaming environment. The simulator can be easily adapted for use with a variety of computation resources on the network.

* Contact author.

1. Introduction

Previous work in the Graphics and Video Laboratory of the Department of Computer Science at the Naval Postgraduate School included the production of a real-time simulator for the Fiber Optically Guided Missile (FOG-M) [Ref. 1, pp. 19-27]. The FOG-M simulator displayed a real-time, three dimensional, *missile's eye view* of terrain and vehicles driving over that terrain. The FOG-M simulator used digital terrain elevation data from the Defense Mapping Agency and a Silicon Graphics, Inc. IRIS-3120 graphics workstation.

The moving vehicle simulator (VEH) is a continuation of the FOG-M research [Ref. 2]. The goal of the follow-on study is twofold. The first objective is to provide a stand-alone vehicle motion simulator. The second objective is to provide more realistic targets that, through networking, can be used by the FOG-M simulator. One noteworthy aspect of the

simulator is that the operator can display the out-the-windshield view of any vehicle during program execution. The moving vehicle simulator has been incorporated into a Mobility Expert System (MES) and could easily be adapted for use by other simulators modeling off-road vehicle motion. It is the intent of this study to present the results of the design, development, and implementation of the moving vehicle simulator and the networking capabilities incorporated into the system.

2. Background

The moving vehicle simulator models the motion of remotely piloted vehicles, such as jeeps, tanks, or trucks, one of which is designated the *driven* vehicle. The *driven* vehicle models a vehicle with an on-board video camera capable of transmitting live pictures of the battlefield to a distant operator's console. The moving vehicle simulator displays a real-time, three-dimensional, driver's view perspective of the terrain, and other vehicles. When networking is enabled, the FOG-M missile is also visible. An interactive user interface and a two-dimensional contour map display allow the operator to establish the desired simulator configuration (stand-alone or networked with the FOG-M simulator) and to define each vehicle to be used in the simulation. The vehicle locations, courses, speeds, and the selection of a driven vehicle are determined using a two-dimensional contour map display.

Once the simulation begins, a three-dimensional view of the terrain is displayed. The operator can interactively control the motion of the vehicle designated as the driven vehicle. The operator controls the driven vehicle's course, speed, and line-of-sight "look" direction by the knobs on a dial box. The viewing volume of the driven vehicle can be controlled by the mouse.

3. Terrain Database

Both the moving vehicle simulator and the FOG-M simulator use a digital terrain elevation database provided by the Defense Mapping Agency (DMA) to draw the three-dimensional scene. This data is stored as an array of sixteen bit data points that represent the ter-

rain of Fort Hunter-Liggett, California. The upper three bits represent the height of the vegetation at that data point. The lower thirteen bits represent the terrain elevation, without the vegetation height [Ref. 3, pp. 2]. The terrain elevation data file is formatted to match the two-dimensional array used to store it during program execution. Data points for ten lengths of ten kilometers are stored a row at a time, from west to east along a row's length, and from south to north, going from row to row. This matches the C compiler storage mapping function for two-dimensional arrays.

The ten kilometer by ten kilometer area of missile flight is sectioned into one hundred meter squares, with each square consisting of two triangles (Figure 1). The triangles are used to construct a colored, three-dimensional terrain display. Values for the triangles' coor-

Figure 2 First Quadrant Drawing Order Example

ordinates are determined prior to missile flight. A separate program converts the elevation height values from feet to meters, reads and scales the terrain data from the master data file, and formats the converted data into the file used by the moving vehicle simulator. Raw elevation values are scaled exponentially by a factor of 1.05 to provide a more esthetic display.

4. Graphics Hardware

The moving vehicle simulator is implemented using a Silicon Graphics, Inc. IRIS 3120 high performance color graphics workstation. The workstation uses a Motorola 68020 microprocessor and is available for under \$30,000. The workstation also uses custom VLSI chips to provide hardware clipping and matrix transformations. The high speed, pipeline architecture allows the performance of viewing, modeling, projection and display device transforma-

Figure 3 Octant Scan Lines

tions at a much greater rate than would be possible in software. The graphics hardware can be conceptually depicted as three pipelined components: the applications/graphics processor, the geometry pipeline, and the raster subsystem. The geometry pipeline and the raster subsystem are controlled by the applications/graphics processor [Ref. 4, pp. 1-1]. The IRIS provides a double buffer display system with a resolution of 1024 by 768 pixels.

5. Hidden Surface Elimination

Hidden surface elimination is accomplished by a real-time implementation of the painter's algorithm. The painter's algorithm simply draws objects in the scene in depth sorted (furthest to nearest) order [Ref. 5, pp. 266]. For the terrain, the correct polygon drawing order for hidden surface elimination is an easily computable function of the line-of-sight of

the vehicle currently being operated (Figure 2). The number of grid squares drawn is minimized by partitioning the entire viewing circumference into octants. The drawing order of each grid square within an octant, from furthest to nearest, is based on a scan line algorithm (Figure 3a). If the line-of-sight is in the eighth octant, the scan lines are defined by indices *startx* and *startz*. *Startz* is incremented until a *stopz* is reached. *Stopz*'s are determined by the field of view calculated from the viewer's position. Before *startz* is incremented, all vehicles located in the grid square that was just drawn are also drawn. One vertical scan line is shown in (Figure 3b). The next scan line is drawn by moving the *startx* one position closer to the viewer and repeating the process. This process is repeated until all grid squares in the octant are drawn.

After the entire scene is constructed, the vehicles in the viewer's grid square are drawn again. This is done to ensure that the vehicles drawn in adjacent grid squares are "painted over" by vehicles in the viewer's grid square.

Vehicles located in the center of a grid square are drawn immediately after the grid square that they occupy is drawn. Vehicles crossing grid square boundaries are drawn only once. The grid square that they are drawn in is determined by the quadrant they are in and the boundary the vehicle is crossing. A vehicle is drawn in an adjacent grid square only if it is near certain edges. The edges are determined by the painter's algorithm and are shown in Table 1.

<u>Quadrant</u>	<u>Grid Square Edge</u>
0	South, West
1	South, East
2	North, East
3	North, West

Table 1 Vehicle Grid Square Adjustment Table

An illustrative example of the methodology employed in the drawing process is provided. In Figure 4, the line-of-sight from the driven vehicle 'A' is in quadrant one. With this line-of-sight, vehicles near a southern or eastern grid square edge are drawn after the adjacent grid square in that direction rather than in the grid square the vehicles occupy. Vehicle 'B' in Figure 4 is located at the southern edge of grid square three. Since the painter's algorithm draws grid square three before grid square four, the part of the vehicle overlapping grid square four would be "painted over" by grid square four if the vehicle was drawn in grid square three. To correctly draw the vehicle and both grid squares it overlaps, the vehicle must be drawn after grid square four.

6. Vehicles

In the moving vehicle simulator, the vehicles are created as graphical objects. Each polygon of each vehicle is drawn by defining its vertices and colors, and then drawing the polygon using a call to a polygon fill function. All objects are created using backface polygon removal and the painter's algorithm to display an undistorted view of a three-dimensional, light shaded object from any viewing angle above the ground plane.

Target vehicle objects (jeeps, trucks, tanks) are built during program initialization. After the objects are constructed, they are animated and oriented to the terrain. A vehicle's course and speed are used to calculate its new position based on the distance it would have traveled in the time required to refresh the screen. Each vehicle defined is associated with an element of one of three global two-dimensional arrays. There is one array for each of the three types of vehicles. The values stored in the arrays are the integer names of the graphical objects to be drawn in each terrain grid square. All vehicles present in one grid square are associated with the same element of the array. All commands required to draw each type of vehicle are collected into the same graphical object. Vehicles are displayed by drawing the terrain grid square and then accessing the appropriate two-dimensional array to draw the vehicles that are present in that grid square.

7. Vehicle Data Structures

The moving vehicle simulator uses two data structures to manage the vehicle display. A linked list of vehicle definition data is created before the display loop begins and is updated with each pass through the loop. Each structure in the linked list contains all the data required to transform and orient a vehicle object to the correct position on the terrain. One object for each type of vehicle is created before the display loop begins. The drawing commands in these objects are used to draw every vehicle of that type used in the display.

The second data structure manages vehicle hidden surface removal. A single two-dimensional array maintains the connection between the grid squares and the order that the

Figure 5 Update Vehicle Grid

vehicles present in the grid square must be drawn. Each element in the array contains a list of pointers to records in the vehicle definition list for the vehicles that should be drawn immediately after drawing the terrain grid squares. The lists are maintained in depth sorted order (furthest to closest) from the *driven* vehicle. The grid square that a vehicle should be drawn in is determined by the vehicle's proximity to a grid square edge and the direction of the line-of-sight. As a result, a vehicle is drawn only once, regardless of its position on the terrain. As a vehicle overlaps a grid square, its position in the two-dimensional array changes. Figure 5 shows how the array changes while maintaining the linked list depth sorted order. All the functions used to draw the vehicles and terrain are performed in the display loop. Each

pass through the loop represents one frame of animation. By optimizing the functions, a frame rate that simulates a real-time display is achieved.

8. Software Implementation

The AT&T Unix System V operating on the IRIS workstation supports Fortran, Pascal, Franz Lisp, an optimized C language compiler and a complete graphics library. The C programming language was selected for implementation of the vehicle simulator to be compatible with the original FOG-M simulator [Ref. 1, pp. 19-27]. Additionally, the communications packages developed at the Naval Postgraduate School are all implemented in C [Ref. 6].

The moving vehicle simulator can be divided into two operational modes: stand-alone mode and networked mode. The stand-alone mode provides an environment where the operator can simulate driving vehicles over the selected terrain. In the networked mode, the moving vehicle simulator provides realistic targets for the FOG-M simulator.

8.1 Stand-Alone Mode

There are two fundamental sections of the stand-alone mode: the initialization phase and the vehicle driving simulation phase. The initialization phase provides an environment for vehicle definition and interactive input of vehicle course, speed, and position on the terrain. Additionally, the operator determines the desired mode (stand-alone or networking) in this phase. The driving phase provides an environment that dynamically updates the terrain displays in real-time based on operator controlled changes to the *driven* vehicle's speed, course, and viewing volume. The operator also designates the driven vehicle.

8.1.1 Initialization Phase

The initialization phase is the interactive input component of the moving vehicle simulator program. The display screen is partitioned into three areas (Figure 6). A large square area (768 by 768 pixels) on the left part of the screen represents the two-dimensional con-

tour map of the ten kilometer area over which the vehicles will operate. The contours are created from the elevation data in the DMA digital terrain elevation database. The map is color coded based on elevation points. The current menu is located in the upper right corner of the display. Instructions corresponding to the current menu are displayed in the lower right corner of the screen.

During this phase, the operator can define vehicles by moving the cursor on the contour map using the mouse. When the desired vehicle location on the map is selected, the coordinates are locked in by pressing the left mouse button. An icon image of the vehicle appears on the map at the specified location. The operator then moves the cursor in the direction of the desired vehicle course. A rubberband line, originating at the icon image, shows the potential vehicle course. Pressing the left mouse button locks in the course represented by the direction of the rubberband line from the vehicle's defined location. A slider speedometer appears in the menu area to allow the operator to set the vehicle's speed by moving the cursor and pressing the left mouse button. Once all desired vehicles have been defined, the actual simulation can begin.

8.1.2 Vehicle Driving Simulation

The driving simulation phase provides successive real-time terrain displays to the operator as the vehicle moves over the terrain. The simulation begins with the designation of a driven vehicle selected from the previously defined vehicles. The driven vehicle is selected by moving the cursor over the vehicle's icon image on the map and then depressing the left mouse button. Selection of a vehicle starts the display loop of the simulation. In networked mode, the vehicle simulator waits until the missile launch occurs before entering the display loop.

The driving display is partitioned into four areas (Figure 7). The large square area to the left (768 by 768 pixels) represents the out-the-window view as seen from the driven vehicle. An operating menu is displayed in the upper right side of the screen that allows the

Figure 6 Contour Map for Vehicle Placement

Figure 7 Tanks in Line Formation

operator to change vehicles or terminate the program. A contour map with the position of the driven vehicle and its viewing volume is displayed on the right, center section of the screen. The driven vehicle's speed, view direction and available operator controls are shown in the lower right section of the screen.

8.2 Networked Mode

The moving vehicle simulator is the first attempt at the Naval Postgraduate School to produce a network of real-time, interactive moving platform simulators. The network communication protocol selected is normal (blocking) socket I/O [Ref. 6]. Blocking I/O allows synchronous operation of the FOG-M and moving vehicle simulators. A pair of sockets is used to transfer and guarantee delivery of the socket stream data between the two simulators. The moving vehicle simulator acts as the server to the client FOG-M simulator.

Operating the moving vehicle simulator in conjunction with the FOG-M simulator requires establishing network data paths. This is accomplished through the creation of dedicated sockets for read and write paths for both control and data. Failure to establish the communications paths causes the simulators to default to the stand-alone mode of operation.

Prior to missile launch, the missile operator's console is provided with relevant vehicle information; i.e., the number and types of vehicles defined. Handshaking takes place after initial data transfer and before entering the display loop to allow either console to abort the simulation. If either simulation is aborted, the other can continue in stand-alone mode. After completion of the initial set-up, the FOG-M simulation console waits for the vehicle definition data from the moving vehicle simulator before allowing missile launch. The moving vehicle simulation waits for the launch event before entering the display loop to insure simulator synchronization. Regardless of the number of vehicles in the missile flight area, only the driven vehicle's information is sent to the missile console. The position of the other vehicles is predicted based on their initial position, course and speed.

The missile simulator transfers a status flag to the moving vehicle simulator indicating if the missile is still in flight. If the missile is still flying, it sends missile position and course data. If it is no longer flying, it sends the identity of the vehicle destroyed.

9. System Features and Limitations

Currently, the system allows only one console of each simulator type in a dedicated link arrangement to be networked together. To insure synchronization, a console can not proceed past a socket read until the information is obtained. This *lock-step* execution prevents the vehicle console operator from changing the driven vehicle while the missile is in flight.

As in the FOG-M simulator, the inability to display the terrain using the 12.5 meter samples available in the terrain data file is another limitation of this simulator. To utilize the 12.5 meter samples would require some 64 times more triangles in the terrain display. The simulator uses 100 meter samples and that reduces the degree of variation in the terrain surface. The use of 100 meter samples is all the IRIS-3120 can currently support for real-time display.

System performance for the networked mode, stand-alone mode, and the mobility expert system (MES) are shown in Table 2.

<u>Simulator Mode</u>	<u>Number of Vehicles</u>	<u>Frames Per Second</u>
Networked	1 (static)	2.6
	10 (static)	1.9
	1 (dynamic)	1.4
	10 (dynamic)	1.2
Stand-Alone	1 (static)	5.7
	10 (static)	4.0
	1 (dynamic)	5.3
	10 (dynamic)	4.3
MES	1 (dynamic)	3.7
	10 (dynamic)	3.3

Table 2 Display Update Rates

Figure 8 Program Hierarchy

Static refers to the type of vehicle objects drawn in the original FOG-M simulator. *Dynamic* refers to vehicle objects that more closely reflect normal vehicle dynamics over natural terrain. The vehicle dynamics modeled in the MES are more complicated than the dynamics modeled in the other simulators, resulting in a slower frame update rate.

10. VEH as a Visualization Tool for a Mobility Expert System

Above, we describe the moving vehicle simulator as either stand-alone or as a networked player to the FOG-M simulator. It is actually an important visualization tool. Research is ongoing to develop new applications around the moving vehicle simulator. An enhanced version of the moving vehicle simulator is being used in conjunction with a Mobility Expert System (MES) currently under development at the Naval Postgraduate School.

10.1 MES Goals and Objectives

The development of expert system based coordination algorithms for groups of autonomous vehicles is the major objective of the MES project. The second objective is to develop the software necessary to create motion simulation of the system using realistic vehicle dynamics over a computer generated terrain model. For purposes of this study, the prototype system developed closely follows the model of the FMC autopilot [Ref. 7]. The program hierarchy is shown in Figure 8.

The MES is a system using four different computer architectures, three programming languages, four networking packages, three operating systems and an expert system shell. The four computer architectures used are: the Symbolics 3600 line of LISP Machines, the Texas Instrument Explorer LISP Machine, the Silicon Graphics, Inc. IRIS Graphics Workstation, and the Digital Equipment Corporation VAX 11/785. The operating systems utilized in the project are the Unix operating system (4.3BSD and ATT System V.3), the Symbolics Genera system and the Texas Instruments Explorer system. The languages implementing the system are Prolog, C, and Lisp with flavor extensions. The expert system shell used is the KEE expert system.

A high level Command and Control Subsystem (CCS) is simulated on a LISP Machine and a VAX. The CCS provides centralized autonomous command and control functions to the individual tanks and acts as a single interface to the autonomous vehicles in the unit. This allows an isolation of observable phenomena for the tactical assessment function as well as centralizing the focus of one problem in the research area.

Simulated tanks with the characteristics of the existing FMC Autonomous Land Vehicle are modeled as in [Ref. 7]. The model is conceptually organized into two distinct parts: (1) the graphics instantiation, with vehicle controller functions on the IRIS, and (2) the rule-based, expert system behavior, implemented on the Lisp Machines. The tanks operate autonomously in much the same way as the FMC vehicle [Ref. 7]. Specifically, each tank

possesses a simulated vision capability, an autopilot, and the ability to send vehicle steering and reference velocity commands to a vehicle controller.

10.2 Autonomous Tank Rules

Individual tanks perform according to the algorithm presented in Figure 9. The autopilot possesses capabilities in addition to those being developed at FMC [Ref. 8]. These extra capabilities allow the vehicle to act as an integral part of a tactical autonomous unit. A tank's designated place in a tactical formation is based on the commands sent to it from the lead tank. The tank maintains its station in the formation until it receives new commands. Currently the tanks use three sets of simple rules that allow the vehicles to assume a line, column, or file formation [Ref. 9]. For each formation, each tank possesses knowledge about who it is, the type of formation, its guide vehicle, and the vehicles that should be to its flanks, front and rear. Rules for each formation are divided into four functional categories: collision avoidance, speed determination, direction determination, and stationing. These rules are presented in Figures 10 through 13.

An autonomous tank is comprised of a set of functions that reside on a LISP machine. The autonomous tank's controller and graphics object reside on the IRIS. Each LISP machine controls a graphically rendered tank on the IRIS battlefield during a simulation run. The Lisp functions perform the algorithms presented in Figures 9 through 13. Each LISP machine generates task commands that are sent to the individual tank that it controls. The LISP machines also determine the approximate time interval required for the tank to respond to the task command.

The tanks perform a simulated visual scan of the environment in the IRIS and produce high-level observations about the battlefield. These observations are used to perform tactical assessments and create tasks to accomplish goals using rule-based inference engines. A rule-based inference engine is a program that processes *if<circumstances>then<do-task>* type expressions. These expressions are constructed through the interrogation of an expert.

Loop

Check for commands from the Command and Control Subsystem.

If change in formation, acquire rules and facts
necessary from disk storage and implement.

Perform a visual scan of the environment.

For each object identified:

Establish its position in reference to the
tank's body coordinate system.

Approximate its future location at beginning
of next iteration of the algorithm.

Produce low level observations about the
object as input to the task generator.

EndFor

Generate tasks in the task generator using the low level
observations and knowledge and rules necessary to
complete currently assigned goals.

*Display diagnostic information and explanations for each
task generated.*

Execute communications tasks to Command and Control
subsystem.

Execute tasks generated by communicating sequences
of vehicle steer and reference velocity commands
to the vehicle controller residing on the IRIS.

EndLoop.

Figure 9 Autonomous Tank Control Algorithm

Avoid Collision To The Right:

If
the vehicle is or will be too close to an object, and
the object is to the right of the vehicle,
Then
move to the left.

Avoid Collision To The Left:

If
the vehicle is or will be too close to an object, and
the object is to the left of the vehicle,
Then
move to the right.

Avoid Collision Ahead:

If
the vehicle is or will be too close to an object, and
the object is ahead of the vehicle,
Then
If
not enough time to maneuver,
Then
Stop.
ElseIf
able to maneuver,
Then
maneuver around object in flank
with greatest maneuvering room.

Avoid Collision From Behind:

If
the vehicle is or will be too close to an object, and
the object is behind the vehicle and closing,
Then
match the object's speed.

Figure 10 Collision Avoidance Rules

Change Speed:

If
vehicle is on course with its guide vehicle, and
vehicle is behind or ahead of its station,
Then
change speed to move vehicle to position by
next iteration of tank algorithm.

Match Speed:

If
vehicle is on course with its guide vehicle, and
vehicle is on station with its guide vehicle,
Then
match speed of the guide vehicle.

Stop:

If
guide vehicle is stopped, and
vehicle on station with guide vehicle,
Then
stop vehicle on station.

Figure 11 Speed Determination Rules

Turn Left:

If
vehicle is off course from its guide vehicle and
relative right to the direction of guide vehicle's
course,
Then
turn left the angular difference to come about.

Turn Right:

If
vehicle is off course from its guide vehicle and
relative left to the direction of guide vehicle's
course,
Then
turn right the angular difference to come about.

Figure 12 Direction Determination Rules

Close Right With Guide:

If
vehicle is too far from guide, and
vehicle is left of guide, and
guide vehicle is normally vehicle's right vehicle,
Then
move to the right.

Close Left With Guide

If
vehicle is too far from guide, and
vehicle is right of guide, and
guide vehicle is normally vehicle's left vehicle,
Then
move to the left.

Assume Correct Position in Relation to Guide:

If
vehicle is on course with guide, and
vehicle is left/right of guide,
but vehicle should be right/left of guide,
Then
drop behind guide,
turn 90 degrees right/left,
proceed until past guide,
turn 90 degrees left/right.

(1 WILL BE TOO CLOSE TO 3)
(VEHICLE IS 1)
(FORMATION IS LINE)

Figure 15 Reasoning about Future Events

Typical tasks, such as those generated for formation keeping, are vehicle referent velocities and directions. These tasks are transmitted to the vehicle controller residing on the IRIS. The vehicle controller then executes the tasks and communicates feedback information to the requesting Lisp Machine.

10.3 A Single Iteration of Start-the-Battle

Figure 14 presents a single iteration of the tank algorithm for tank 1 operating in conjunction with two other vehicles, tank 2 and tank 3. The information in Figure 14 is taken from the display of the Lisp Machine designated as tank 1. Figure 14a shows both tank 1 and tank 2's grid coordinates, course, speed, and information about tank 2's position, course, and speed relative to tank 1. Figure 14b shows the same information for tank 3. Figure 14c shows the rules needed to move a tank to the right. Figure 14d shows the rules used for a line formation for maintaining a separation interval between two tanks. Figure 14e shows the rule used when tank 2 is the guide tank and tank 1 is too far ahead of the guide tank. As a result, tank 1 is ordered to stop. Once the guide tank catches up, another set of rules (not shown) is used to order tank 1 to increase speed.

The tanks reason about the IRIS battlefield world relative to their own individual body coordinate systems. The tanks reason about time by approximating positions, dispositions, and possible intentions of objects in view during possible future event time frames. Tanks also continuously re-evaluate their individual circumstances as well as their vehicle controller's response time to a direction or velocity command. This allows a tank to predict and address future events. Figure 15 provides an example.

In Figure 15, $x3rel$ and $z3rel$ are the x and z coordinates of tank 3 relative to tank 1 at time t . The variable $x3nxt$ and $z3nxt$ are the predicted x and z coordinates of tank 3 relative to tank 1's predicted future location at time t' . Tank 1 will be too close to tank 3 because the horizontal interval distance will exceed the value of a constant measure called *proper-interval* as tank 1 approaches tank 3 from behind. The *proper interval* is the required distance

Figure 16 Moving to the Line of Departure

Figure 17 Crossing the Line of Departure

Figure 18 Deploying at the Final Coordination Line

Figure 19 Assaulting the Objective

between two tanks in the formation. This distance varies depending on the type of formation being executed. When the distance between the two tanks is less than the *proper interval*, a task is generated by tank 1 to increase the distance between the two tanks.

10.4 A Typical Test Mission

Figures 16 through 19 illustrate a typical test mission. Figure 15 depicts the movement from an assembly area. The initialization phase for the IRIS has been conducted, the tactical assessment carried out, and four LISP machines have been initialized to drive four of the tanks in the unit. The guide vehicle for the unit, driven by a human operator on the IRIS, has been given an initial direction and speed. The jeep was then selected to view the formation as it turned to its left to assume a column formation. The picture was taken from the jeep.

Figure 17 depicts the column after crossing the line of departure and conducting movement to contact (going out and engaging the enemy). The guide vehicle is the lead tank in the column. To obtain the picture, the jeep was driven to a known destination of the lead tank. The jeep then was positioned to get a view as the column approached.

Figure 18 depicts the actions at the final coordination line. The unit deployed into a line formation and is about to move through the objective. This deployment was effected with the help of manual intervention. The guide tank was stopped at the final coordination line by a human operator. This forced the column to halt by initiating certain station keeping rules. The function application of *Start-the-battle* was allowed to expire upon each LISP machine. A new formation was then acquired by each LISP machine. The function *Start-the-battle* was then re-applied upon each LISP machine. The human operator assumed control of the guide vehicle while the autonomous, LISP machine driven tanks then assumed their positions in the line formation after about 30 seconds of maneuvering.

Figure 19 depicts a flanking view of the line of tanks as they assault an objective. The line is sweeping past the stationary jeep from which the picture was taken. The fifth tank in the line decided to maneuver around the other side of the jeep and is not depicted.

10.5 MES Implementation

The MES system is distributed across the various specialized architectures in accordance with hardware capabilities. Thus, it was possible to create an entirely satisfactory real-time system at low cost. The current suite of equipment allows up to five individual tanks to operate on the battlefield represented on the IRIS.

Performance bottlenecks occur during communication processing on the IRIS. This is because each tank spawns a send and receive process to communicate to a Lisp machine. The performance bottlenecks on the Lisp machine side are in relation to the sequential nature of the command and control system's execution. The problem is that the vision and inference operations are not concurrent or continuous. The LISP machine must ask the IRIS for vision information and then wait until the IRIS collects and returns the vision information. Once it has the information, it uses the information to make inferences about the tank it is controlling relative to the other tanks on the battlefield.

11. Conclusion

We have described how one extends the capabilities of inexpensive three-dimensional visual simulators on individual workstations to the networked workstation environment. Individual graphics workstations are easily grown out of as our applications become more sophisticated. We grow out onto a network of workstations to allow for other players or to partition our system into processes computed by separate machines. For the system described above, the partitioning across machine boundaries has been expensive due to the lack of readily available networked graphics and computing software facilities. We expect this to change as high-performance graphics workstation manufacturers recognize the impor-

tance of distributed graphics and computational functionality. Ideas such as location independent computing and location independent graphical objects are a step in the right direction.

We have also shown how the notion of inexpensive three-dimensional visual simulators as visualization tools can lead to better understanding for typically graphics-less areas such as expert systems. Three-dimensional simulators that can be readily "plugged-into" diverse computational environments present a viable alternative for the future. To accomplish this goal, we need to make our three-dimensional visual simulators inexpensive and adaptable.
