IDA Log No. HQ 88-33762

DEFINITIONS

IDA publishes the following documents to report the results of its work.

Reports

Reports are the most authoritative and most carefully considered products IDA publishes. They normally embody results of major projects which (a) have a direct bearing on decisions affecting major programs, or (b) address issues of significant concern to the Executive Branch, the Congress and/or the public, or (c) address issues that have significant economic implications. IDA Reports are reviewed by outside panels of experts to ensure their high quality and relevance to the problems studied, and they are released by the President of IDA.

Papers

Papers normally address relatively restricted technical or policy issues. They communicate the results of special analyses, interim reports or phases of a task, ad hoc or quick reaction work. Papers are reviewed to ensure that they meet standards similar to those expected of refereed papers in professional journals.

Memorandum Reports

IDA Memorandum Reports are used for the convenience of the sponsors or the analysts to record substantive work done in quick reaction studies and major interactive technical support activities; to make available preliminary and tentative results of analyses or of working group and panel activities; to forward information that is essentially unanalyzed and unevaluated; or to make a record of conferences, meetings, or briefings, or of data developed in the course of an investigation. Review of Memorandum Reports is suited to their content and intended use.

The results of IDA work are also conveyed by briefings and informal memoranda to sponsors and others designated by the sponsors, when appropriate.

The work reported in this document was conducted under IDA's Independent Research Program. Its publication does not imply endorsement by the Department of Defense or any other government agency, nor should the contents be construed as reflecting the official position of any government agency.

Approved for public release; distribution unlimited.

INSTITUTE FOR DEFENSE ANALYSES

IDA Independent Research Program

PREFACE

This report publishes the results of an investigation of the costs of procuring peculiar ground support equipment (PGSE) and automated test equipment (ATE). It presents data on a number of items of such equipment. It also presents the results of analyses to derive cost estimating relationships for PGSE and ATE.

The work was supported by IDA's fund for central research. The report was reviewed by the Cost Analysis and Research Division.

The authors gratefully acknowledge the aid given by the Facilities Equipment Branch of the Air Force Logistics Command, the Defense Logistics Services Center of the Defense Logistics Agency, and the Automatic Test Systems Division of the San Antonio Air Logistics Center in providing the data on ATE. They also wish to thank Dr. Stephen Balut for his valuable suggestions and comments and Mr. Robert Simmons for his substantial contributions to the form and style of the report.

I. INTRODUCTION AND FINDINGS

A. INTRODUCTION

The purpose of this exploratory analysis was to develop relationships for estimating the procurement costs of certain items of support equipment, namely, peculiar ground support equipment (PGSE) and automated test equipment (ATE). The first task was to find and gather data on the procurement costs and the characteristics of the equipment, data which could be of use in developing cost estimating relationships (CERs). This was a time consuming and disappointing phase of the project. Cost analysis of support equipment has been a neglected area of defense cost analysis, and the armed services are only now beginning to construct data bases with consistent and complete information.

The second task was to use the data to construct CERs. Using the data sets in Appendixes A, B, and C, we constructed three types of relationships—one type for the cost of PGSE and two for the cost of ATE. In the first type, the procurement cost of PGSE was related to the quantity and unit cost of the aircraft subsystem the PGSE supported.¹ In the second type, the cost of ATE was related to the number of test program sets (TPS) used with the ATE and to the number of line replaceable units (LRUs) the ATE was designed to test. In the third type, the cost of ATE was related to the characteristics of the test equipment.

To estimate CERs for PGSE, we used regression analysis and historical budget data on 27 aircraft that were being procured during 1970-85. A separate regression analysis was carried out for each major subsystem of the aircraft—airframe, engine, and avionics.

To estimate CERs for ATE, we used regression analysis, again, and two different sets of data on ATE that were obtained from logistical organizations in the Air Force and from the Defense Logistics Agency. In the analysis of the relationship between the cost

¹ This analysis was an attempt to provide an alternative to the method the Office of the Secretary of Defense (OSD) uses to verify the services' projections of aircraft PGSE costs: calculating the ratio between the cost of PGSE and the cost of the aircraft and using these historical ratios as a yardstick to judge the reasonableness of current PGSE budgets.

and characteristics of ATE, separate regressions were performed on different characteristics of the equipment.

B. FINDINGS

The study's general finding is that the costs of support equipment can, in fact, be related to variables obtained from the kinds of data bases that are being constructed by the services. Our results offer some insight into how such costs are related to their determinants, and the CERs for PGSE are reliable enough to justify their use for forecasting.

The study's specific findings are as follows:

1. The cost of procuring PGSE is closely related to the quantity and the unit cost of the subsystem the PGSE supports. The relationship holds for each major subsystem of an aircraft—airframe, engine, and avionics.
2. The cost of procuring ATE is generally related to the number of line replaceable units the ATE is designed to test, but not to the number of test program sets.
3. The unit cost of depot-level ATE is closely related to the volume of the equipment. On the other hand, the cost of ATE is poorly related to the equipment's year of installation (a proxy for year initially procured and thus level of technology) as well as its weight, surprising findings that might change with more and better data.

II. COSTS OF PECULIAR GROUND SUPPORT EQUIPMENT

A. DATA

To estimate the CERs for PGSE costs, we used yearly figures on procurement of aircraft and PGSE from FY 1970 through FY 1985 in 24 Navy and 3 Air Force programs. The data (Appendix A) are given by major subsystem:²

- Quantity of aircraft procured
- Airframe costs
- Airframe PGSE costs
- Engine costs
- Engine PGSE costs
- Avionics (electronics) costs
- Avionics PGSE costs.

We calculated "total" variables by summing the yearly figures over the total period for each subsystem of each aircraft. The costs were escalated to constant FY 1988 dollars before summation.

B. COST ESTIMATING RELATIONSHIPS

The CERs for aircraft PGSE are presented below. Only 20 data points were used because seven of the aircraft programs had only fragmentary data and so we eliminated them from the analysis. Costs are in millions of FY 1988 dollars. The independent variable "AC" stands for the number of aircraft procured. The figures in parentheses under the explanatory variables are the levels of statistical significance (calculated from t-statistics)

² Although these figures were obtained from budget documents, we used entries in the "prior year" column, which are close to actual expenditures. For example, the figures listed for FY 1973 in Appendix A were taken from the budget submitted to the Congress in 1975.

for the regression coefficients (the exponents). We used an exponential specification because we found that it fit the data better.³

$$\text{Airframe PGSE cost} = .013 (\text{AC})^{1.32} (\text{unit airframe cost})^{1.19} \quad R^2 = .81$$

(.1%) (.1%)

$$\text{Engine PGSE cost} = .097 (\text{AC})^{.95} (\text{unit engine cost})^{.65} \quad R^2 = .84$$

(.1%) (1%)

$$\text{Avionics PGSE cost} = .67 (\text{AC})^{.85} (\text{unit avionics cost})^{.78} \quad R^2 = .88$$

(.1%) (.1%).

The airframe equation, for example, relates what the services spent during 1970-85 to procure PGSE for the airframe of an aircraft to the number of aircraft procured during the period and the unit cost of procuring the airframe, obtained by dividing the total cost of airframes by the number of aircraft procured. The equation estimates that, given recent budget trends, the services have been spending roughly \$220 million dollars on PGSE to support a buy of 200 airframes costing \$10 million each ($.013 \times 200^{1.32} \times 10^{1.19} = \220).

We are interested in how well these equations explain the data used to estimate them and thus how well the equations might predict the future in the absence of large changes in unmeasured variables. (Inflation is not one of these unmeasured variables, since all costs are in FY 1988 dollars.) The R^2 of .81 for the airframe equation, for example, shows that the number of aircraft and the unit cost of the airframe together explain 81 percent of the variability in the program cost of the airframe PGSE. The predictive powers of the engine and avionics equations are even higher.

Moreover, the t-statistics of the three equations show that the numbers of aircraft and the unit costs of the airframe, engine, and avionics are highly related to the PGSE costs. For convenience, we have shown the levels of statistical significance rather than the t-statistics themselves. These figures show that, although there were only 20 data points, the exponents of the explanatory variables in these equations pass statistical significance at the 0.1-percent level (except for the 1-percent level for unit engine cost in the second equation). In empirical studies, a 10-percent level is customarily regarded as "good," a 1-percent level is "excellent", and a 0.1-percent level is beyond reproach. In other words, it

³ The CERs in this paper were obtained by linear regression on the variables transformed to natural logarithms. To obtain the equation for airframe PGSE cost, for example, we estimated $\ln(\text{airframe PGSE cost}) = a + b \ln(\text{AC}) + c \ln(\text{unit airframe cost})$ and then took the antilog of the result.

is highly unlikely that the explanatory variables in the equations presented above are *not* predictors of the cost of PGSE.

Given that we are using exponential relationships, the values of the exponents have a simple interpretation for forecasting. In the airframe equation, for example, a 10-percent increase in the number of aircraft procured would lead to a 13-percent increase (10×1.32) in the total cost of airframe PGSE. Similarly, a 10-percent increase in the unit cost of the airframe would lead to a 12-percent increase (10×1.19) in the total cost of airframe PGSE. The fact that these exponents have high statistical significance gives us some confidence in using these relationships to forecast the percentage change in PGSE cost associated with changes in number of aircraft procured and the unit airframe cost.

On the other hand, it is surprising that, in contrast with engine and avionics PGSE costs, an increase in the unit airframe cost and, especially, in the number of aircraft procured should lead to a greater than proportional increase in airframe PGSE cost. Because of economies of scale, we should expect that an increase in the number of aircraft procured would lead to a less than proportional increase in PGSE cost. Further research is needed to examine why this was not the result for airframes.

III. COSTS OF AUTOMATED TEST EQUIPMENT

A. DATA

We constructed two data sets to relate the costs of ATE to potential explanatory variables. Data on each item that is being managed under the Air Force's Modular Automated Test Equipment (MATE) concept were supplied by the Automatic Test Systems Division at the San Antonio Air Logistics Center. From these data we constructed the variables in Appendix B:

- Number procured
- Unit cost
- Number of test program sets (TPSs)
- Number of line replaceable units (LRUs).

The other set (in Appendix C) includes the following data on every item of ATE stocked at depots (Air Logistics Centers) that has a unit cost over \$100,000:

- National Stock Number (NSN)
- Unit cost in then-year dollars
- Year installed
- Volume (cubic feet)
- Weight, for only a few items (pounds).

The stock numbers, costs, and years were provided by the Facilities Equipment Branch of the Air Force Logistics Command. We grouped items by NSN and used their costs and installation years to derive a single, representative cost and installation date for each NSN. Where there were several units of an item with the same cost but different installation dates, we assumed that they were from the same procurement lot and chose the single cost for the NSN. This cost was escalated to FY 1988 dollars by use of the deflator for "Other Procurement, Air Force." The earliest installation date observed for the lot was used to select the value of the deflator.

Because the level of technology is a major determinant of the cost of equipment in general, we sought a variable to capture the level of technology of the ATE and used the

earliest installation date as a proxy measure for this purpose. The procurement date would have been a better proxy for the level of technology when the item was designed and built, but it was not available.

Where several units with the same NSN had *different* costs on different installation dates, we assumed that they were from different lots and thus represented independent measures of cost. We escalated each cost to FY 1988 and took a simple average to obtain the representative cost for that NSN. The first installation year was chosen to depict technology, as before.⁴

The Defense Logistics Services Center provided the data on volume and weight, the latter for only a few items.

As a final step, on the assumption that the relation between the cost and characteristics of ATE varies with the type of equipment, we assigned each item to one of the following classes and used dummy variables to control for this variable: component (tube, power supply, etc.), T1; engine tester, T2; electronic subsystem tester, T3; maintenance fixture, T4; and inertial navigation set tester, excluded case.

B. REGRESSION RESULTS

The equations listed below show the results of the regression analyses designed to relate the cost of ATE to explanatory variables: in Equation 1, the number of LRUs; in Equation 2a, the volume and type of equipment; and in Equation 2b, the weight of the equipment. The statistical results of these equations are poorer than those of the CERs for PGSE costs; the values of R^2 are lower and the measures of statistical significance are not as strong. Moreover, the equations do not include several variables that were tried and found to be poorly related to the cost of ATE.

1. ATE Cost Versus TPSs and LRUs

The results of this analysis were as follows. Eight data points were used.

$$\begin{aligned} \text{ATE cost} &= .23 \text{ LRU}^{.61} & R^2 &= .35 \\ & (10\%) \end{aligned}$$

⁴ There were several "mixed" cases in which some items came from the same lot (had the same costs) but there were several lots. Here, we simply took an average of the various lot costs in constant dollars. For the measure of initial installation year we selected the earliest year among all items in all lots.

The equation shows that ATE cost was somewhat related to the number of LRUs the equipment is designed to test. The number of test program sets is not included because its coefficient had low statistical significance.

2. ATE Cost Versus ATE Characteristics

The results of the analyses of ATE costs and characteristics are shown below. Eighty-one data points were used in the first analysis; seven, in the second.

$$\text{a. ATE cost} = .302 (\text{volume})^{.12} (.59)^{T1} (.22)^{T2} (.56)^{T4} \quad R^2 = .23$$

(1%) (5%) (5%) (1%)

$$\text{b. ATE cost} = .0169 (\text{weight})^{.51} \quad R^2 = .31$$

(20%)

We can be confident that volume is a predictor of ATE cost, since its exponent is statistically significant at the 1-percent level (Equation 2a). The value of the exponent, 0.12, implies that a 10-percent increase in volume leads to a 1.2-percent ($10 \times .12$) increase in ATE cost.

The levels of significance of the dummy variables are also high, which demonstrates the importance of controlling for the type of equipment in future work.⁵ The third dummy variable (T3) is not included because of low statistical significance, which indicates that electronic subsystem testers have a similar relationship between ATE cost and volume to that of inertial navigation set testers, the excluded case.

The year of installation is also excluded from Equation 2a, again because its coefficient was found to have low statistical significance. This suggests that the level of technology has little effect on ATE cost, a somewhat surprising result.

The fact that weight has low statistical significance in Equation 2b is surprising, in that the costs of many defense systems, including entire ships, are estimated by applying cost-per-pound factors to various items of equipment, or weight groups. The sample size is small, however. Note also that the volume of the equipment, which proved quite reliable in Equation 2a, is not included in the regression expressed in Equation 2b because its coefficient had a very low level of statistical significance when weight was included. This

⁵ The dummy variables for the types of equipment were entered linearly in the regression equation: $\ln(\text{ATE cost}) = a + b \ln(\text{volume}) + c(T1) + d(T2) + e(T4)$.

suggests that further research, conducted with more and better data, should re-examine the question whether volume, weight, or both, provide better predictions of ATE cost.
