19. ABSTRACT (Continue on reverse if necessary and identify by block number) New tools for the computational simulation of ion and ion-pair dynamics in the gas phase and in solution have been developed. Both classical and quantum mechanical methods were explored. Monte-Carlo techniques for incorporating thermodynamic equilibrium effects of surrounding solvent molecules have been incorporated into the computer codes. New techniques for computing highly accurate weak interaction energies among anions and solvent molecules have been developed and tested.

The general problem on which our efforts were focused during this grant period dealt with the solvation of ions and ion pairs. We explored the fundamental intermolecular interaction energies among the ion (or ions) and the surrounding solvent molecules. Statistical methods for incorporating the effects of thermodynamic fluctuations in the solvent molecules were also built into our computer simulation capabilities. Finally classical and quantum dynamics tools were used to simulate and study the time evolution of solvent clustered ion pairs which have been excited either thermally or by photochemical means.

The primary result of findings of this grant are detailed in the publications listed below. The names of the people who worked on these projects are also given below. The primary achievement of this effort is the development of state-of-the-art computer simulation techniques for the study of structural, energetic, thermodynamic, and dynamic properties of ions and ion pairs in solution. Earlier progress reports, including the final progress report submitted in August of 1988 provide further details on the specific ions and on pairs which we studied.
