19. ABSTRACT (Continued on reverse if necessary and identify by block number)					
Each military service groups its entry-level jobs into clusters based on similarity of aptitude requirements. The configuration of these systems differs by service. The Air Force has four job clusters, labeled Mechanical-M, Administrative-A, General-G, and Electronics-E, which have been used in only slightly modified form since the early 1950s. The purpose of this report is to describe results from an application of a new procedure for homogeneous clustering of regression equations in an Air Force Armed Services Vocational Aptitude Battery (ASVAB) validity study involving 155,000 recruits in 211 technical training programs. Empirical clusters are derived and explained in terms of specialty composition and aptitude profiles. Other potential applications of the procedure are briefly discussed.

SUMMARY

Each military service groups its entry-level jobs into clusters based on similarity of aptitude requirements. The configuration of these clustering systems differs by service and ranges in number from four in the Air Force to 11 in the Navy. Some of the systems have been in existence for some time despite changes in selection tests and job content. The Air Force has used essentially the same four composite groupings (Mechanical-M, Administrative-A, General-G, and Electronics-E) since the early 1950s. The purpose of this report is to apply a new procedure for homogeneous clustering of entry-level jobs, based on similarity of prediction equations, to a recent set of Air Force entrant data. Specific interest was directed at whether or not the four-group M, A, G, and E solution would emerge from the empirical relationships.

Individual training records were assembled for all persons entering Air Force technical training who took the Armed Services Vocational Aptitude Battery (ASVAB) Forms 8, 9, and 10. Subtest scores in standard score form were recorded, together with final school grade. After editing for missing data, there were 154,000 cases, representing each of 211 technical training programs. Regression equations were obtained within each program using the 10 ASVAB subtests as predictors and final school grades as criteria. The individual equations were then hierarchically clustered based on similarity of the regression weights. Once the terminal clusters had been formed, composite regression equations were obtained to examine the profiles of abilities required within each cluster. Baseline equations were also obtained for comparative purposes within each of the four existing M, A, G, and E job clusters.

Results focused on discussion of the last six stages of the hierarchical solution. Four of the six groups were approximately equivalent to the current M, A, G, and E clusters in terms of both job content and profiles of regression weights. The fifth and sixth groups identified were notable in a number of respects. The fifth group was composed of a mixed set of specialties with one characteristic in common; namely, performance in training was not well predicted by any of the ASVAB subtests. Regression weights were uniformly low for all subtests in this equation. Further inspection of this group revealed schools of three basic types: (a) those with little or no cognitive demands, (b) those with significant cognitive demands presumably outside the scope of the present ASVAB, and (c) advanced training schools. The latter two types were seen to offer the most fertile ground for expanding the coverage of the current battery or for developing special purpose selection instruments. The final (sixth) group was noteworthy in that it contained relatively few specialties--primarily those in the areas of tactical and strategic aircraft maintenance. Based on the salient weights for the subtests, these specialties appeared to require ability across the whole spectrum of the battery. Success in training was essentially a joint function of the technical subtests normally associated with these occupations (i.e., Auto and Shop Information, Mechanical Comprehension) and the more academically oriented subtests such as Arithmetic Reasoning, Word Knowledge, and Paragraph Comprehension. This was interpreted to be evidence of an emerging requirement for "generalists" who demonstrate a relatively broad range of talents across the whole domain of abilities as measured in the ASVAB. Implications for changes in the classification structure, test content, and composite configurations are discussed.

PREFACE

The Air Force Human Resources Laboratory is tasked by Air Force Regulation 35-8, Air Force Military Personnel Testing System, with conducting research and development in support of the Armed Services Vocational Aptitude Battery (ASVAB). The current effort was accomplished under Project 7719, Force Acquisition and Management System, Task 771918, Personnel Qualifications Tests, and Work Unit 77191846, Development and Validation of Enlisted Selection Methodologies.

The authors wish to acknowledge the assistance provided by Sgt Thomas Sackett and Ms. Suzanne Farrell of the Information Sciences Division for data analyses support and by Ms. Elizabeth Knippa for typing the draft report.

CLASSIFICATION OF AIR FORCE JOBS INTO APTITUDE CLUSTERS

I. INTRODUCTION

The four Air Force selection composites--Mechanical (M), Administrative (A), General (G), and Electronics (E)--have been in use in one form or another since the mid-1950s (Weeks, Mullins, & Vitola, 1975). Each refers to a particular Armed Services Vocational Aptitude Battery (ASVAB) subtest configuration for use in selecting and classifying recruits into one of four job clusters also categorized into M, A, G, and E groups. The evolution of the system as it presently exists was guided by a mix of expert judgment and analysis of empirical relationships between the subtests and performance in Air Force training. It represents an attempt to group similar career fields based on their aptitude requirements such that a minimal amount of information is lost in the classification process. The four-group solution was a compromise between having only one broadly defined general ability composite applicable to all career fields and having a separate composite for each career field. The former was thought to be too inaccurate for differentiating among the wide diversity of occupations, each with its own unique requirements; and the latter was too cumbersome for operational purposes.

Since the mid-1950s, there have been several changes in both the composition of the tests and Air Force career fields. In 1973, the Air Force selection test in use since 1950 was replaced by the ASVAB, a joint-service test. Several content areas were dropped--most notably, Pattern Comprehension and Hidden Figures; several were added; and others were changed in character. There have also been changes in Air Force specialties (AFSs) as the content of Air Force jobs changed subtly, and in some cases dramatically, over the past 20 years. Training programs underwent corresponding changes as they were updated to reflect current procedures and innovations in technology. Some AFSs were deleted, some were added, and some changed in ways that were not as noticeable. In the intervening years, there have also been advances in analytic capabilities which allow for more sophisticated techniques for job clustering. Given these circumstances, it seemed appropriate to revisit the composites to see how well they reflect today's personnel and training environment. The purpose of this document is to report on a homogeneous clustering of technical school prediction equations, with a view toward comparing a recent empirical solution to the traditional MAGE composite structure. In the process of conducting these analyses, it was expected that some implications could also be drawn about an enduring theoretical controversy over the relative importance of a single generalized measure of cognitive ability ("g" factor) versus the use of multiple ability measures in personnel selection. This issue has been raised anew by recent findings which suggest that (a) job requirements can be characterized mainly in terms of overall demand for cognitive ability (Hunter, 1980; Hunter, 1986; Jensen, 1986; Schmidt, Hunter, and Pearlman, 1981; Thorndike, 1985) and (b) this factor is so dominant that unique patterns of specific abilities play a relatively minor role in determining a person's occupational success. If true, then multiple aptitude batteries and multiple composites would seem to have little utility in the context of personnel selection decisions.

II. METHOD

Predictor Variables

Individual records were assembled for all persons who had been administered ASVAB Forms 8, 9, and 10 and who had completed an Air Force technical training program. Scores for the ASVAB subtests, as shown in Table 1, were recorded in both raw score and standard score form (Ree, Mathews, Mullins, & Massey, 1982). Standard scores range from 20 to 80 and have an overall mean of 50 and a standard deviation of 10 in the 1980 standardization group. After removal of records without a numeric final school grade, there were 154,844 cases in the sample. Descriptive data for the sample are shown in Table 2.

Table 1. ASVAB Forms 8, 9, and 10 Subtests and Composites

Subtest	Testing time (minutes)	Number of items	Type
General Science (GS)	11	25	Power
Arithmetic Reasoning (AR)	36	30	Power
Word Knowledge (WK)	11	35	Power
Paragraph Comprehension(PC)	13	15	Power
Numerical Operations(NO)	3	50	Speed
Coding Speed (CS)	7	84	Speed
Auto and Shop Information (AS)	11	25	Power
Mathematics Knowledge (MK)	24	25	Power
Mechanical Comprehension (MC)	19	25	Power
Electronics Information (EI)	9	20	Power

Composite	Subtest composition
Mechanical (MECH)	MC + GS + 2AS
Administrative (ADMIN)	NO + CS + (WK + PC)
General (GEN)	(WK + PC) + AR
Electronics (ELECT)	AR + MK + EI + GS

Table 2. Sample Score Ranges, Means, and Standard Deviations

Subtest	Range		Mean	SD
	Min	Max		
General Science	22	68	54.10	7.26
Arithmetic Reasoning	29	66	54.71	6.88

Mechanical Comprehension	25	70	55.05	7.85
Electronics Information	25	69	54.50	7.60

Note. N = 154,844.

Performance Criteria/Specialties

Success in technical school was measured by the final school grade recorded at the end of training. These values are expressed as percentages, usually between 60 and 100. Overall, there were 211 different technical schools represented. Each had more than 100 attendees; some had considerably more. Attendance ranged from 100 to 15,584. The average course size was 734 people.

Analyses

For records within each of the 211 schools, regression analyses were performed with final school grade as the criterion and the ASVAB subtests as predictors. In the analysis, all of the predictors were permitted to draw a least squares regression weight as appropriate in the solution (exhaust option).

A modified hierarchical grouping (HIER-GRP) analysis was performed on the resulting equations (Ward, Treat, & Albert, 1985). In this procedure, predicted scores were generated for all recruits in the sample across all courses by applying the course-specific regression weights to each recruit's ASVAB subtest score. Technical school equations were then grouped on the basis of similarity of their predicted score vectors, beginning with 211 separate equations and ending with a single consolidated equation.

A traditional four-group MAGE solution was also derived for comparative purposes. For these analyses, specialties as described in AFR 39-1 were grouped into one of the M, A, G, or E areas according to the designated selector aptitude index (AI). Specialties with multiple AIs listed (e.g., M or E) were included in both clusters. This operation resulted in four (minimally overlapping) sets of specialties from which subtest equations were derived. The resulting equations were then compared with those obtained in the empirical solution to determine similarities and differences in subtest weighting patterns.

III. RESULTS

The grouping diagram shown in Figure 1 depicts the last six stages of the modified hierarchical clustering. Inspection of the group composition (also shown in Appendix A) indicated that Clusters A, B, and C corresponded approximately to the traditionally defined Administrative, General, and Electronics groups respectively. Of the total of 25 specialties in Cluster A, 48% had an Administrative requirement in AFR 39-1. Principal Administrative specialties contained in the cluster included Personnel Specialist and Financial Management Specialist (see Table 3). In Cluster B, there were 30 specialties, of which 70% had a General requirement. This cluster contained Security Specialist, Medical Services Specialist, and Command and Control Specialist. Cluster C contained 83 specialties, of which 70% were listed as having an Electronics requirement. Included in this cluster were Ground Radio Communications Specialist, Avionics Instrument Systems Specialist, and Airborne Early Warning Radar Specialist. Cluster D, which contained 30 specialties, was difficult to characterize on the basis of the jobs included. There was good reason for this as will be noted later. Cluster E was a mix of mechanical maintenance and craftsman jobs. Of the 37 specialties included, 81% had a Mechanical requirement. Jet Engine Mechanic, General Purpose Vehicle Mechanic and Construction Equipment Operator were included in this cluster. Cluster F was the smallest in terms of the number of specialties included (6), although a relative large number of people were assigned to the specialties. These were almost exclusively AFSs associated with Tactical and Strategic Aircraft Engine Maintenance.

Table 4 shows the regression weights corresponding to each of the groups. The weights indicate which of the ASVAB subtests contribute to the prediction of training success within each of the clusters. There were distinct patterns observed, some of which did not correspond to the present composites. The equation for Cluster A included relatively large weights for the AR, WK, PC, CS, and MK subtests while the equation for Cluster B included GS but not CS. The main distinguishing features of this equation were the higher weights on GS and WK relative to the Cluster A equation. The salient weights in the Cluster C equation were AR, PC, MK, and EL. The equation for Cluster D was notable in that none of the subtests had a consequential weight, indicating that these career fields were not well predicted by subtests in the current ASVAB. This is why Cluster D was difficult to characterize earlier on the basis of specialty content. The equation for Cluster E was distinguished by large weights on AR, AS, MK, and EL. Finally, Cluster F appeared to draw salient weights on all subtests except NO and CS.

Figure 1. Hierarchical Grouping Diagram.

Table 3. Six-Cluster Specialty Composition

Cluster	N	No of AFSs	Description	Representative specialties
A	25,357	25	Predominately Administrative	Personnel Specialist; Personnel Affairs Specialist; Financial Management Specialist; Civil Engineering Resources Management Specialist; Inventory Management Specialist; Freight Traffic Specialist.
B	41,070	30	Predominately General	Security Specialist; Medical Services Specialist; Medical Lab Specialist; Intelligence Specialist; Command and Control Specialist; Nuclear Weapons Specialist; Plumbing Specialist.
C	38,509	83	Predominately Electronics	Ground Radio Communications Specialist; Electronic Computer and Switching System Specialist; Avionics Instrument Systems Specialist; Avionic Communications System Specialist; Airborne Early Warning Radar Specialist.
D	11,552	30	Mixed	Cryptologic Linguist Specialist; Precision Measuring Equipment Laboratory Technician; Fabrication and Parachute Specialist; Fire Protection Specialist; Fuel Specialist; Chapel Management Specialist; Education and Training Manager.
E	26,906	37	Predominately Mechanical	Aircraft Environmental Systems Mechanic; Jet Engine Mechanic; Aircraft Pncudraulic Systems Mechanic; Aircraft Armament Systems Specialist; General Purpose Vehicle Mechanic; Construction Equipment Operator.
F	11,450	6	Tactical/Strategic Aircraft Maintenance	Helicopter Mechanic; Tactical Aircraft Maintenance Specialist; Strategic Aircraft Maintenance Specialist; Metal Fabricating Specialist.

MAGE Solutions

Table 5 shows the regression weights derived from the current MAGE job clusters. Similarities can be noted between these equations and those presented in Table 4. To make comparisons easier, bar charts were constructed (Figure 2) to show the subtest weights side by side. The equation for Cluster A aligns fairly closely with the Administration equation; Cluster B, with the General equation; and Cluster C, with the Electronics equation--although this similarity is less than the previous two. Finally, the Cluster E equation bears moderate resemblance to the Mechanical equation. Clusters D and F have no analogous equations in the present composite structure.

IV. DISCUSSION

The homogeneous clustering of technical school regression equations revealed a pattern of job clusters and corresponding composites that, at the six-stage solution, yielded four groups/composites that closely resembled the current MAGE system. This finding was rather remarkable considering the extent of changes that have presumably taken place over the past 35 years in both test content and the composition of the specialty training programs.

The enduring nature of the MAGE distinctions, however, should not obscure the fact that individual specialties may indeed have changed sufficiently to warrant dissolution or perhaps reclassification from one to another of the MAGE categories. In fact, there is strong likelihood that some of the categories have grown or diminished in absolute size over time. One could speculate that the absolute size of the Electronics cluster--which would have been rather small initially--now represents the second largest group in terms of numbers of people and is by far the largest group in terms of number of specialties.

Two additional groups/composites (Clusters D and F) were newly defined in this analysis. The first group was characterized by low weights across all the ASVAB subtests. Career fields included represent those for which the present subtests have little predictive power and would thus be fertile ground for additional research. Examples of at least three types were apparent. Some career fields seemed to have few cognitive demands. Success in training was principally a function of factors other than ability as defined in the ASVAB. For these kinds of assignments, there are likely no new cognitive tests that would assist in discriminating between those who will or will not succeed. This does not rule out the potential value of some non-cognitive assessment. Other career fields included in this group are of a quite different character. They require abilities that appear to be outside the domain of the ASVAB but which potentially are measurable with new advances in cognitive assessment. It has long been known, for example, that spatial factors are not well represented in ASVAB nor are psychomotor abilities. The third class of the technical schools which were not well predicted fell into the category of "Advanced" courses given at the 5- and 7-skill levels. Here, the effects of prior experience begin to attenuate the relationship between entry level aptitudes and success in training.

The other newly defined group (Cluster F) seems to represent jobs which are very complex and highly demanding with respect to the ASVAB subtests. They require abilities across the whole spectrum of presently available measures. The prevailing ASVAB requirements of this group suggest a need for "generalists" as opposed to "specialists" for entry into these specialties; i.e., persons who demonstrate proficiencies in academic as well as technical domains. It is not clear whether this group existed in earlier analyses or whether it represents an emerging requirement. In any case, it is sizable and if it increases over time, may put additional pressures on recruiting resources to obtain people with this ability pattern. Some consideration may also have to be given to forming a new composite for these specialties--one that draws from all subtest areas.

The different patterns of ability detected for the six empirical groups also suggests something about the ASVAB and its ability to distinguish among specialties (i.e., its differential prediction capabilities). There has been a vast amount of speculation about whether a single composite would work about as well as separate composites (Hunter, 1980; Hunter, 1986; Jensen, 1986; Schmidt et al., 1981; Thorndike, 1985). The evidence found here suggests that there are different equations underlying success in these specialty clusters. The amount of difference depends on how the common versus unique contributions are measured. It seems clear though that the battery has differential prediction value and that its potential may not be fully capitalized upon at present. As a rough approximation, the predictive accuracy associated with six equations ($R^2 = .30$) was compared with that associated with a single common equation ($R^2 = .21$). The difference was statistically significant ($p < .001$), with the multiple equations representing a 42% increase in predictive accuracy as measured by R^2 change over use of a single equation. The magnitude of these differences might be mitigated somewhat by overfitting; but with the sample sizes involved, this effect was likely to be minimal. Overall, the results are not consistent with the position that a single composite (presumably measuring "g") suffices to predict achievement across occupationally diverse training areas.

They are consistent with the view that tasks in different training areas can and do reflect unique requirements that can be assessed only with a multiple test battery using separate prediction composites.

From a test perspective, not all the subtests seemed to perform as well as might be expected. NO, CS, and, to a certain extent, MC made weaker contributions than did the other subtests. Both NO and CS are "speeded tests," whereas MC is a power test. NO had little to contribute to any of the specialty groups. CS made modest contributions to the Administrative and General clusters whereas MC affected primarily the General group--but to a lesser extent than the other subtests. These results could mean that speeded requirements are slight in these clusters or that the NO subtest is not as well suited to measuring "speeded" abilities as it could be. Further research on these issues seems warranted.

The modified hierarchical grouping procedure used in the analysis represents a significant step forward in comparison to procedures traditionally used for these purposes. It yielded results that were easily obtained and readily interpretable, and that could have direct implications for making the job clusters more homogeneous with respect to aptitude requirements. On the testing side, the procedure could also be useful in generating composites that are optimally formed to measure the relevant aptitude dimensions. A unique feature of this analysis technique allows for grouping based only on the coefficients associated with the test variables--and ignoring the coefficients on the unit vectors (course constants). This means that the clustering is not driven by overall differences in the level of grades assigned within each of the courses. Although these may not differ by much in the present context, this source of equation heterogeneity could be much more influential with other types of dependent measures (e.g., job tenure, supervisory ratings).

There are several research contexts in which the modified procedure could be applied: (a) development of test composites and job assignment clusters for classification of officers/aircrew; (b) clustering equations that predict personnel tenure; (c) various policy modeling and policy capturing exercises that support the Weighted Airman Promotion System (WAPS); and (d) training R&D settings where one might want to distinguish aptitude by treatment combinations that maximize overall training achievement.

V. CONCLUSIONS

1. The present system of grouping technical schools and forming composites into four sets (MAGE) was found to be remarkably robust considering the myriad of changes that have taken place since the system was first established. Four of the six groups defined by an empirical clustering of subtest regression equations strongly resembled the currently defined MAGE subgroups.

2. Evidence was found that the ASVAB subtests could differentiate among Air Force enlisted job clusters. To be sure, the clusters share much in common; however, the equations seem to have different characteristics which were in line with expectations about what ought to be required in the broadly defined training programs. This would seem to argue for a continued reliance on multiple composites rather than reverting to a single generalized measure of cognitive ability.

3. As opportunities arise, modifications should be made to both the career field clusters and the prediction composites defined in AFR 39-1, to improve the alignment between composites and specialty groups.

4. A number of specialties are not well predicted (Cluster D)--some because they have few cognitive demands and some because the demands they make are not sufficiently represented in the current ASVAB. Each type should be studied further--especially those career fields that require test measures beyond those currently found in the ASVAB.

5. Consideration should be given to forming a new cluster/composite based on the sixth group identified in this study (Cluster F). The tactical/strategic aircraft maintenance specialties included in the group seemed to reflect a "generalist" requirement--one that required abilities across the full domain of subtest measures.

6. Some consideration should be given to replacing or upgrading some of the present ASVAB subtests--particularly NO, CS, and MC, since they had salient weights on few, if any, of the job clusters.

7. From a methodological standpoint, the modified HIER-GRP procedure provides a meaningful analysis technique that would also be useful in other contexts (officer selection and classification, forming composites based on other criteria, etc.).
