An error analysis of a hypothetical target tracking system developed around an ongoing real-time attitude (RTA) project at the Space Programs Laboratory was performed at the U.S. Army Engineer Topographic Laboratories. An extensive set of tables of target errors was developed as a function of a variety of collection geometries and system component random errors. The target tracking system includes RTA, a real-time positioning capability, an automatic target sensor, and a slant range measuring device. The system components were characterized in the study by their expected random errors. For example, the real-time positioning capability in this study reflects the expected range of GPS errors. <i>Robert [unclear] (101)</i>

PREFACE

This study was conducted under DA Project 4A762707A855, "Topographic Mapping Technology."

The study was conducted during the summer of 1987 under the supervision of Donald R. Barnes, Chief, Space Concepts Division, and Dr. Joseph J. Del Vecchio, Space Programs Laboratory, U.S. Army Engineer Topographic Laboratories.

The author extends special thanks to Ms. Leslie Butera, a summer employee from James Madison University, who assisted with the computer programming.

COL David F. Maune, EN, was Commander and Director, and Mr. Walter E. Boge was Technical Director of the U.S. Army Engineer Topographic Laboratories during the report preparation.

TARGET LOCATION ERRORS DERIVED FROM A HYPOTHETICAL TARGET TRACKING SYSTEM

INTRODUCTION

This study was performed in support of two ongoing efforts at the Space Programs Laboratory (SPL), U.S. Army Engineer Topographic Laboratories (ETL) -- namely an ETL initiated, U.S. Army Corps of Engineers (USACE) approved, NASA shuttle experiment intended to validate the concept of precision real-time attitude (RTA) keyed to a digital imaging stellar camera -- and a continuing SPL effort entitled "Target Location and Analysis." An expanded concept involving an RTA capability is to combine it with a real-time positioning system, such as the NAVSTAR/Global Positioning System (GPS), to develop a capability for both real-time attitude and positioning (RTAP) or exterior orientation of a space platform. If the initial RTA shuttle experiment is successful, an RTAP concept validation experiment would be pursued as a follow on. If such a capability exists, then the possibility of real-time target location exists. The purpose of this study is to evaluate the performance of a hypothetical target tracker system developed around a real-time exterior orientation system comprised of RTA and GPS.

Two additional components are conceived and combined with RTAP to develop the hypothetical target tracker system. The first component is a device that measures slant range to an object imaged at the principal point of the second component, namely a solid state detector located in the focal plane of an optical system. The hypothetical target tracker system is described in figure 1.

The four components of the target tracker system are specified in this study by their individual random errors rather than by their physical description. For example, two star cameras are depicted in figure 1 to represent the RTA capability. This is not necessarily a complete representation of RTA, since an operational RTA might require argumentation with an inertial component. Nor has it been determined that two star cameras, specifically, will be required. The RTA capability will be realized in this study by expressing resultant random errors from RTA as attitude errors of the optical reference system of the target sensor/camera (TC). The detector type (visual or IR for example) has not been specified, nor has the optical system. Errors in TC are expressed as angular errors in target direction measured in the target camera system. The slant range measuring component (R) is defined only with respect to slant range random errors to the object imaged at the principal point of TC. Four GPS satellites are shown in figure 1, but the GPS performance is defined with respect to an expected range of position errors of the target tracker (P). The origin of P is the instantaneous location of the lens position of TC in the ground coordinate frame (G).

The error results for target location determination presented in appendices H and I pertain to random input errors from the four components of P. Biases caused by inaccurate determination of locking angles between component coordinate frames, inaccurate interior orientation of the several cameras, lack of simultaneity of time determination, and other factors are not analyzed in this study.

Mathematical Description of the Error Analysis

The error propagation function provided by the theory of least squares adjustment is used in this study to express expected errors in target determination as functions of input component random errors. The mathematics associated with least squares are described in the appendices to this report. Appendix A develops the basic condition equations for three separate observation modes of Cases I-III. Appendixes B and C address the model simulation and model coordinates generation, respectively. The description of the (3x3) covariance matrix of the adjusted target coordinates is given in appendix D. Note that the position coordinates derived from GPS are also treated as parameters to be adjusted. The associated weight matrix for the several (up to 5) tracker positions is described in appendix E. One reason for doing this is so that the Case I observation mode will be weighted only with respect to errors in the observed measurement, namely the slant range error variance. The slant range observation is described in equation 1 of appendix A.

Another reason for treating the several target tracker positions as weighted parameters is so that the Case II observation mode weight will be independent of GPS errors. The Case II mode, namely direction to the target from P, is described in equation 2 of appendix A. An argument could be made for treating the Case II observation in the same manner as the Case I observation by regarding the RTA input (3 angles of exterior orientation) to the attitude of TC in G as parameters to be adjusted. In this way, the Case II observation weight would depend only on the target coordinate measuring errors and would be independent of the RTA attitude errors. Note that the target coordinate measuring errors are errors in X_t/f and Y_t/f , where (X_t, Y_t) are the target coordinates and f is the focal length of the optical system. Thus, the target coordinate errors noted as target errors in the tables of appendix H are regarded as angular errors in the X and Y directions, respectively. The main reason for not treating RTA input as weighted parameters was to reduce the size of the required matrix inversion. For example, if the target was observed by five target trackers, then a (33x33) matrix must be developed and inverted instead of an (18x18) matrix.

Least squares adjustment requires an overdetermined linear system of equations as input. Since the observation equations labeled Case I and Case II are nonlinear in the unknown parameters, a "linearized" approximation to the observation equations is employed. The approximation and the associated contribution to the inverse of the required covariance matrix is given in appendix F for Case I, and in appendix G for Case II.

Target location errors are heavily dependent on collection geometry as well as on random input measuring errors. For example, errors in target location increase as distance to the target increases in Case II and Case III. Case III is the mode where slant range and direction to the target are both measured. Case III pertains when the four components of the hypothetical target tracker are employed. On the other hand, if slant range to the target only is used (3 of more Case I observations), then target error is not dependent on distance to the target. If two or more observations are made on a target, then the relative position of the two or more target trackers with respect to one another and with respect to the target greatly influences target precision. Generally, as the angle between target trackers as measured from the target increases, then target precision increases. Symmetric geometric models described in appendix C were used for this error analysis. The models are such that each target tracker is the same distance from the target and adjacent target trackers make the same angle with respect to the target. The user of the error analysis results given in appendix H and I should be aware of the associated collection geometry and should not extend error predictions beyond the input error set, nor beyond the collection system configurations.

The error results given in appendixes H and I are 99 percent confidence sphere radii derived from the (3x3) target covariance matrices. The average value of the trace of the covariance matrix was used to generate the 99 percent confidence radius. Two assumptions lay behind this calculation. The first is that the input random errors are normally distributed variables. The second assumption is that, in general, the collection geometry is such that neither of the three coordinate errors can be expected to be smaller or larger than the other two. Then if σ^2 is the average value of the trace, then $(\Delta x^2 + \Delta y^2 + \Delta z^2)/\sigma^2 = R^2/\sigma^2$ is a chi square variate with 3 degrees of freedom. The confidence sphere radius is derived from the following probability statement

$$\text{Prob}(R^2/\sigma^2 < \chi^2_{3,\gamma}) = \gamma$$

where γ is the required confidence value. Tabular entries in appendix H and I are 99 percent confidence sphere radii in meters. Means to convert the tabulated values to other values of γ are given in the appendix.

Numerical Runs

A series of computer runs was performed to generate the target location errors shown in the 17 tables in appendix H, and the 3 tables in appendix I. The tables in appendix I pertain to range only observations (Case I), whereas those in appendix H pertain to Case II and Case III modes. In each of the tables, whenever pertinent, the error and geometric variables vary according to the following:

Target Errors (Arc Seconds)	1.0, 2.0, 3.0, 4.0, 5.0
Attitude Errors (Arc Seconds)	0.5, 1.0, 2.0, 3.0
Slant Range Errors (Meters)	10.0, 15.0, 20.0
Position Errors (Meters)	1.0, 5.0, 10.0, 15.0
Distance (Meters/ 10^6)	0.5, 1.0, 2.5, 5.0, 7.5, 10.0, 12.5, 15.0
Separation Angle (Degrees)	15.0, 30.0, 45.0, 75.0

There are several exceptions to the above. Target errors in table H-1 were extended to include: 10.0, 15.0, 20.0, 25.0, and 30.0 seconds of arc. A 60.0 degree separation angle was added to the list of tables I-1, I-2, and I-3. A separation angle is the angular distance between adjacent target trackers.

The tables in appendix I are organized by an additional parameter, namely k , the correlation factor described in appendix E. As k increases to 1.0 and as the slant range error approaches 0.0, the target coordinate error approaches the GPS error. This can be visualized by considering the rigid figure comprised of the target at a vertex and the several target trackers equal distance from the target, where adjacent target trackers are equal distance from one another. If the individual target tracker covariance matrices are equal and if they are 100 percent positively correlated with one another, then since the position error is the

only error in the system, the rigid figure will be shifted in G by exactly the GPS error. This means the target error is equal to the GPS error.

Generally, as k increases to 1.0 the target errors either remain the same or decrease. This generality is true for table I-1 where there are no degrees of freedom in the least squares adjustment. However, the results in table I-2 show that when there is one degree of freedom, the target errors increase or remain the same when the separation angle is 60 degrees and 75 degrees. In table I-3 where there are two degrees of freedom, the target errors increase or remain the same when the separation angle is 45 degrees and 60 degrees. There are no results for a separation angle of 75 degrees since it is impossible to have a separation angle larger than 72 degrees in a pentagon model.

The tables can be used in any number of ways to display expected errors. For example, suppose the SEP (50% confidence-radius) is required for the following set of input errors and geometric parameters as the Case III observation mode varies over 2, 3, and 4 trackers.

Separation Angle:	30 degrees
Distance:	2500 kilometers
Target Error:	2 seconds
Attitude Error:	1 second
Slant Range Error:	15 meters
GPS Error:	5 meters

The 99 percent confidence radii are found in tables H-3, H-7, and H-11. A distance of 2500 kilometers translates to a value of 2.5 under the heading DIST. The 99 percent confidence radii are taken directly from the tables and are 58, 47, 40, meters respectively. Each of these values must be multiplied by 0.4566 (See appendix H) to obtain the 50 percent confidence radii, with the results of 26.5, 21.5 and 18.3 meters respectively.

Discussion

The primary reason for this work was to develop an extensive set of target location error tables so that the impact of an RTAP system on target determination could be assessed. A hypothetical target tracker system was conceived with which a variety of geometric configurations, a large error set, and several observational modes were processed to produce target errors. The various target tracker possibilities will not be evaluated in this study.

As was noted in the introduction, biases among the various components were not considered, nor were environmental distortions such as optical and microwave refraction considered. The tables must be used in the same spirit with which they were developed, namely in an ideal geometric world where random errors are independent and normally distributed. The operational modes were developed requiring simultaneity of observation with no concern for the complex communication and coordination problems such observation modes would create. Again, the purpose for the work was to present tables of target errors for subsequent analyses. The prudent user of the tables can interpolate among

parameters within the tables with some confidence, but he must extrapolate beyond the error bounds and beyond the geometric models at his own risk.

Targets in this study were generally regarded as moving targets, hence the stated requirement of simultaneity of observation. There is no reason why the tables cannot be used to evaluate observations taken at different times on fixed targets as long as the parameters that define the tables are not exceeded.

Conclusion

Expected three dimensional target errors can be estimated from the error tables by relating proposed targeting systems to the appropriate geometric model used in the analysis.

Appendix A. Basic Condition Equations

Target coordinates at time t are defined by the following expression:

$$\begin{pmatrix} X_T \\ Y_T \\ Z_T \end{pmatrix}_t = \begin{pmatrix} X_{PI} \\ Y_{PI} \\ Z_{PI} \end{pmatrix}_t + D_{It} \begin{pmatrix} U_{PI} \\ V_{PI} \\ W_{PI} \end{pmatrix}_t$$

$(X_T, Y_T, Z_T)_t$: Target coordinates at time t .

$(X_{PI}, Y_{PI}, Z_{PI})_t$: I^{th} target tracker coordinates at time t .

D_{It} : Slant range distance to target from the I^{th} target tracker at time t .

$(U_{PI}, V_{PI}, W_{PI})_t$: Direction cosines of the ray between the target and the I^{th} target tracker at time t .

$$\begin{pmatrix} U_{PI} \\ V_{PI} \\ W_{PI} \end{pmatrix}_t = M_{PIG_t} \begin{pmatrix} x_t \\ y_t \\ -f \end{pmatrix}_t / l_t ; l_t = (x_t^2 + y_t^2 + f^2)^{1/2}$$

M_{PIG_t} : Rotation matrix relating the I^{th} target tracker reference frame to the ground (G) at time t .

f : Target tracker camera focal distance.

(x_t, y_t) : Image coordinates of target at time t .

Three observation modes are considered in this exercise: Case I, where slant range distance to the target is measured; Case II, where direction to the target is measured; and Case III, where slant range and direction are measured.

Case I

Rewrite the basic equation in the following way:

$$\begin{pmatrix} X_T - X_{PI} \\ Y_T - Y_{PI} \\ Z_T - Z_{PI} \end{pmatrix}_t = D_{It} \begin{pmatrix} U_{PI} \\ V_{PI} \\ W_{PI} \end{pmatrix}_t$$

Perform the vector dot product on both sides of the equation and get

$$(X_T - X_{PI})_t^2 + (Y_T - Y_{PI})_t^2 + (Z_T - Z_{PI})_t^2 = D_{It}^2 \quad (1)$$

Case II

Rewrite the basic equation in the following way:

$$M^T_{PIG_t} \begin{pmatrix} X_T - X_{PI} \\ Y_T - Y_{PI} \\ Z_T - Z_{PI} \end{pmatrix} 1/D_{It} = \begin{pmatrix} x_t \\ y_t \\ -f \end{pmatrix} 1/l_t$$

Perform the matrix multiplication and divide the first and second equations by the third equation to remove D_{It} and l_t .

Let $M_{PIG_t} = \{m_{ij} : i = 1,3; j = 1,3\}$

Note that for convenience, subscript I has been dropped from the matrix elements.

$$\begin{aligned} \frac{m_{11}(X_T - X_{PI}) + m_{21}(Y_T - Y_{PI}) + m_{31}(Z_T - Z_{PI})}{m_{13}(X_T - X_{PI}) + m_{23}(Y_T - Y_{PI}) + m_{33}(Z_T - Z_{PI})} &= -x_{t/f} \\ \frac{m_{12}(X_T - X_{PI}) + m_{22}(Y_T - Y_{PI}) + m_{32}(Z_T - Z_{PI})}{m_{13}(X_T - X_{PI}) + m_{23}(Y_T - Y_{PI}) + m_{33}(Z_T - Z_{PI})} &= -y_{t/f} \end{aligned} \quad (2)$$

Case III

Equations 1 and 2 pertain here.

In Case I, where only slant range is measured, $I \geq 3$. In Case II, where only direction is measured, $I \geq 2$. In Case III, where slant range and direction are measured, $I \geq 1$.

Appendix B. Model Simulation

The orthogonal rotation matrix relating the I^{th} target to the ground frame (G) is derived next. The matrix construction is performed in the following steps:

Step 1: Choose target and target tracker coordinates.

$$T = (X_T, Y_T, Z_T)$$

$$P = (X_P, Y_P, Z_P)$$

Step 2: Compute $D = |T - P|$

Step 3: Set $X_t = Y_t = 0$, i.e. the target tracker optical axis is directed toward the target.

Step 4: Let M_{PIG} be defined by the fundamental angles roll (ω), pitch (ρ) and yaw (K).

$$\text{Let } (\epsilon_1, \epsilon_2, \epsilon_3) = [(X_T - X_P), (Y_T - Y_P), (Z_T - Z_P)]^1 / D$$

then

$$M_{PIG}^T \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix}$$

The relation is true since the target camera optical axis is directed toward the target, then

$$\begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \end{pmatrix} = M_{PIG} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$$

$$\text{and } (\epsilon_1, \epsilon_2, \epsilon_3) = -(m_{13}, m_{23}, m_{33}).$$

The orientation matrix is now fixed except for a yaw angle rotation about the optical axis. Let $K = 180^\circ$, then

$$M_{PIG} = \begin{bmatrix} \epsilon_3/Q & \epsilon_2\epsilon_1/Q & \epsilon_1 \\ 0 & -Q & \epsilon_2/Q \\ \epsilon_1/Q & -\epsilon_2\epsilon_3/Q & -\epsilon_3/Q \end{bmatrix}$$

$$Q = (1 - \epsilon_2^2)^{1/2}$$

Appendix C. Generation of Model Coordinates

Five geometric models are developed to simulate the five situations of 1, 2, 3, 4, or 5 target trackers symmetrically placed with respect to the target. The geometry is such that each target tracker is D from the target and such that adjacent target trackers are S from one another.

One Target Tracker

In this case $X_T = Y_T = Z_T = 0$ and also $Y_P = Z_P = 0$. $X_P = D$

Two Target Trackers

The configuration is described in the following diagram:

The angle α is chosen and the value of S is

$$S = D (2 - 2 \cos \alpha)^{1/2}$$

$$T : (0, 0, 0)$$

$$P_1 : (D \cos \alpha/2, -D \sin \alpha/2, 0)$$

$$P_2 : (D \cos \alpha/2, D \sin \alpha/2, 0)$$

Three Target Trackers

The configuration is described in the following diagram:

$$T: \left[-\frac{\sqrt{3}S}{6}, S/2, (D^2 - S^2/3)^{1/2} \right]$$

$$P_1: (0, 0, 0)$$

$$P_2: \left(-\frac{\sqrt{3}S}{2}, S/2, 0 \right)$$

$$P_3: (0, S, 0)$$

Four Target Trackers.

The configuration is described in the following diagram:

$$T: \quad [S/2, S/2, (D^2 - S^2/2)^{1/2}]$$

$$P_1: \quad (0, 0, 0)$$

$$P_2: \quad (S, 0, 0)$$

$$P_3: \quad (S, S, 0)$$

$$P_4: \quad (0, S, 0)$$

Five Target Trackers.

The five target trackers form a pentagon around the origin.

$$T: \quad [0, 0, (D^2 - Q^2)^{1/2}]$$

$$P_1: \quad (0, Q, 0)$$

$$P_2: \quad (-Q \sin \delta, Q \cos \delta, 0)$$

$$P_3: \quad (-Q \sin \delta/2, -Q \cos \delta/2, 0)$$

$$P_4: \quad (Q \sin \delta/2, -Q \cos \delta/2, 0)$$

$$P_5: \quad (Q \sin \delta, Q \cos \delta, 0)$$

$$\delta = 72^\circ$$

$$Q = S/[2(1 - \cos \delta)]^{1/2}$$

Appendix D. Error Propagation.

The objective of the work is to propagate errors in target tracker position and attitude measurements, target tracker coordinate errors, and target tracker slant range errors into adjusted target coordinate errors. This will be done by regarding the target tracker positions as weighted parameters and by assuming that the other measurements contain random errors only, that is, distortions caused by constant biases are not considered. The (3x3) covariance matrix of the adjusted target coordinates will be the upper (3x3) matrix of the $[3(K+1) \times 3(K+1)]$ covariance matrix of the adjusted parameters derived by least squares methodology. There are $1 \leq K \leq 5$ target trackers for any one situation. The general form of the covariance matrix is given next.

$$\sum_{T,P}^{-1} = \begin{bmatrix} \sum_{I=1}^K R_I & -R_1 & -R_2 & \dots & -R_K \\ -R_1 & R_1 & \phi & \dots & \phi \\ -R_2 & \phi & R_2 & \dots & \phi \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -R_K & \phi & \phi & \dots & R_K \end{bmatrix} + W_P^{-1} \quad (1)$$

$\sum_{T,P}$ is the desired $[3(K+1) \times 3(K+1)]$ covariance matrix.

$$W_P^{-1} = \begin{pmatrix} \phi & \Theta \\ \Theta^T & W_P \end{pmatrix}$$

ϕ : (3x3) matrix of zeros

Θ : (3x3K) matrix of zeros

W_P : (3Kx3K) weight matrix. W_P is defined in Appendix E.

R_I : (3x3) contribution to the covariance matrix from the I^{th} target tracker.

The contents of R_I depend on the kind of observation, i.e. Case I, Case II, or Case III. R_I for Case I is defined in appendix F and R_I for Case II is defined in appendix G. R_I for Case III is the sum of the Case I and Case II contributions.

Appendix E. Target Tracker Coordinate Weight Matrix

The covariance matrix of the 3K target tracker coordinates is assumed to take the following form:

$$\Sigma_p = \begin{bmatrix} \sigma_p & k\sigma_p & \dots & k\sigma_p \\ k\sigma_p & \sigma_p & \dots & k\sigma_p \\ \vdots & \vdots & \ddots & \vdots \\ k\sigma_p & k\sigma_p & \dots & \sigma_p \end{bmatrix}$$

where

σ_p is a (3x3) covariance matrix of position derived directly from GPS error predictions.

$$-1 < k < 1$$

$$\Sigma_p \text{ is } (3K \times 3K)$$

The target tracker coordinate weight matrix is

$$W_p = \Sigma_p^{-1}$$

$$W_p = \begin{bmatrix} \gamma\sigma_p^{-1} & \xi\sigma_p^{-1} & \xi\sigma_p^{-1} & \dots & \xi\sigma_p^{-1} \\ \xi\sigma_p^{-1} & \gamma\sigma_p^{-1} & \xi\sigma_p^{-1} & \dots & \xi\sigma_p^{-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \xi\sigma_p^{-1} & \xi\sigma_p^{-1} & \xi\sigma_p^{-1} & \dots & \gamma\sigma_p^{-1} \end{bmatrix}$$

where

$$\gamma = \frac{1 + (K - 2)k}{(1 - k)[1 + (K - 1)k]}$$

$$\xi = \frac{-k}{(1 - k)[1 + (K - 1)k]}$$

The matrix inversion result can be verified by multiplying W_p by Σ_p and getting I_{3K} .

Appendix F. Contribution to the Normal System Coefficient Matrix for Case I

From equation 1 of appendix A, the condition equation for Case I is

$$(X_T - X_p)^2 + (Y_T - Y_p)^2 + (Z_T - Z_p)^2 = D_{TP}^2$$

Note that the subscripts "I" and "t" have been dropped for convenience. Regard the three target coordinates T as free parameters to be adjusted and regard the three target tracker coordinates p as weighted parameters. The weight matrix is specified in appendix E, and its relation to the normal system coefficient matrix is specific in appendix D.

The linear approximation of the condition equation is

$$\beta \begin{bmatrix} \Delta X_T \\ \Delta Y_T \\ \Delta Z_T \end{bmatrix} - \beta \begin{bmatrix} \Delta X_p \\ \Delta Y_p \\ \Delta Z_p \end{bmatrix} - \Delta D_{TP} = 0$$

where

$$\beta = \left[\frac{X_T - X_p}{D_{TP}}, \quad \frac{Y_T - Y_p}{D_{TP}}, \quad \frac{Z_T - Z_p}{D_{TP}} \right]$$

ΔD_{TP} : unknown random slant range error.

Suppose K target trackers made slant range measurements to the target. If the target is fixed in G, e.g. a non-moving ground target, then the observations can be made at different times. If the target is moving G, then the K observations must be simultaneous. In any case, the K observations are represented by

$$\begin{bmatrix} \beta_1 & -\beta_1 & & \\ \beta_2 & & -\beta_2 & \\ \cdot & & & \cdot \\ \cdot & & & \\ \cdot & & & \\ \beta_K & & & -\beta_K \end{bmatrix} \begin{bmatrix} \Delta T \\ \Delta P_1 \\ \Delta P_2 \\ \cdot \\ \cdot \\ \Delta P_K \end{bmatrix} = \begin{bmatrix} \Delta R_1 \\ \Delta R_2 \\ \cdot \\ \cdot \\ \cdot \\ \Delta R_K \end{bmatrix}$$

[K x 3 (K+1)] [3(K+1)x1] [Kx1]

The slant range observations are assumed to be independent with a common variance σ_R^2 . The weight matrix for the set of K slant range measurements is $1/\sigma_R^2 I_K$. If B represents the $[K \times 3 (K+1)]$ matrix defined above, then the contribution to the normal system coefficient matrix is $B^T (\frac{1}{\sigma_R^2} I_K) B$ or

$$\begin{bmatrix} \frac{1}{\sigma_R^2} \sum_{i=1}^K \beta_i^T \beta_i & -\frac{1}{\sigma_R^2} \beta_1^T \beta_1 & \dots & -\frac{1}{\sigma_R^2} \beta_K^T \beta_K \\ -\frac{1}{\sigma_R^2} \beta_1^T \beta_1 & \frac{1}{\sigma_R^2} \beta_1^T \beta_1 & \dots & \phi \\ \vdots & \vdots & \ddots & \vdots \\ -\frac{1}{\sigma_R^2} \beta_K^T \beta_K & \phi & \dots & \frac{1}{\sigma_R^2} \beta_K^T \beta_K \end{bmatrix}$$

ϕ : (3×3) matrix of zeros.

From equation 1 of appendix D the matrix R_1 is

$$R_1 = \frac{1}{\sigma_R^2} \beta_1^T \beta_1$$

Appendix G. Contribution to the Normal System Coefficient Matrix for Case II

From equation 2 of appendix A the condition equations for Case II are

$$F = \frac{m_{11}(X_T - X_P) + m_{21}(Y_T - Y_P) + m_{31}(Z_T - Z_P)}{m_{13}(X_T - X_P) + m_{23}(Y_T - Y_P) + m_{33}(Z_T - Z_P)} + x/f = 0$$

$$H = \frac{m_{12}(X_T - X_P) + m_{22}(Y_T - Y_P) + m_{32}(Z_T - Z_P)}{m_{13}(X_T - X_P) + m_{23}(Y_T - Y_P) + m_{33}(Z_T - Z_P)} + y/f = 0$$

Note that the subscripts "T" and "t" have been dropped for convenience. Regard the three target coordinates T as free parameters to be adjusted and regard the three target trackers coordinates P as weighted parameters. The weight matrix associated with P is specified in appendix E and its relation to the normal system coefficient matrix is specified in appendix D.

The linear approximation of the condition equations for Case II is

$$\begin{aligned} \frac{\delta(F,H)}{\delta(x,y)} \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix} + \frac{\delta(F,H)}{\delta(\omega, \rho, K)} \begin{pmatrix} \Delta \omega \\ \Delta \rho \\ \Delta K \end{pmatrix} + \frac{\delta(F,H)}{\delta(X_T, Y_T, Z_T)} \begin{pmatrix} \Delta X_T \\ \Delta Y_T \\ \Delta Z_T \end{pmatrix} \\ + \frac{\delta(F,H)}{\delta(X_P, Y_P, Z_P)} \begin{pmatrix} \Delta X_P \\ \Delta Y_P \\ \Delta Z_P \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \end{aligned}$$

From appendix A

$$\frac{\delta(F,H)}{\delta(x,y)} = \frac{1}{f} I_2$$

$$\frac{\delta(F,H)}{\delta(\omega, \rho, K)} = f \begin{pmatrix} 0 & Q & -\epsilon_1 \epsilon_2 / Q \\ -1 & 0 & -1/Q \end{pmatrix} = B$$

$$Q = (1 - \epsilon_2^2)^{\frac{1}{2}}$$

$$\frac{\delta(F,H)}{\delta(X_T, Y_T, Z_T)} = \frac{f}{D_{Tp}} \begin{pmatrix} \epsilon_3/Q & 0 & -\epsilon_1/Q \\ \epsilon_1 \epsilon_2 / Q & -Q & \epsilon_2 \epsilon_3 / Q \end{pmatrix} = C$$

$$\frac{\delta(F,H)}{\delta(X_P, Y_P, Z_P)} = - \frac{\delta(F,H)}{\delta(X_T, Y_T, Z_T)}$$

$(\Delta x, \Delta y)$: Unknown random target image point measuring errors

$(\Delta \omega, \Delta \rho, \Delta K)$: Unknown random attitude errors

The weight matrix for the pair of observation is ω , where

$$\omega^{-1} = \begin{pmatrix} \frac{1}{f^2} I_2 & B \\ \phi^T & \sigma_a \end{pmatrix} \begin{pmatrix} \frac{1}{f^2} I_2 \\ B^T \end{pmatrix}$$

σ_o : (2x2) covariance matrix of (x, y)

σ_a : (3x3) covariance matrix of (ω, ρ, K)

ϕ : (2x3) matrix of zeros

$$\omega = \left[\frac{1}{f^2} \sigma_o + B \sigma_a B^T \right]^{-1}$$

Suppose K target trackers made direction to target measurements. If the target is fixed in G , e.g. a non-moving target, then the observations can be made at different times. If the target is moving in G , then the K observations must be simultaneous. In any case, the K observations are represented by

$$\begin{bmatrix} C_1 & -C_1 & & & \\ C_2 & & -C_2 & & \\ \vdots & & & \ddots & \\ C_K & & & & -C_K \end{bmatrix} \begin{bmatrix} \Delta T \\ \Delta P_1 \\ \vdots \\ \Delta P_K \end{bmatrix} = \begin{bmatrix} \Delta L_1 \\ \Delta L_2 \\ \vdots \\ \Delta L_K \end{bmatrix}$$

[2K x 3(K+1)] [3(K+1) x 1] [2K x 1]

$$L_k = \frac{\delta(F, H)_k}{\delta(x_k, y_k)} \begin{pmatrix} \Delta x_k \\ \Delta y_k \end{pmatrix} + \frac{\delta(F, H)_k}{\delta(\omega_k, \rho_k, K_k)} \begin{pmatrix} \Delta \omega_k \\ \Delta \rho_k \\ \Delta K_k \end{pmatrix}$$

The set of target measurements are assumed to be independent from the attitude measurements; also the target measurements over target trackers as well as the attitude measurements over target trackers are assumed to be independent. These assumptions lead to a $(K \times K)$ diagonal weight matrix where the I^{th} diagonal element is

$$\omega_I = \left[\frac{1}{f^2} \sigma_o + B_I \sigma_{a_I} B_I^T \right]^{-1}$$

If C represents the $[2K \times 3(K+1)]$ matrix defined above, then the contribution to the normal system coefficient matrix is $C^T [\text{Diag}(\omega_i)] C$, or

$$\begin{bmatrix} \sum_{i=1}^K C_i^T \omega_i C_i & C_1^T \omega_1 C_1 & . & . & . & -C_K^T \omega_K C_K \\ -C_1^T \omega_1 C_1 & C_1^T \omega_1 C_1 & . & . & . & \phi \\ . & . & . & . & . & . \\ . & . & . & . & . & . \\ . & . & . & . & . & . \\ -C_K^T \omega_K C_K & \phi & . & . & . & -C_K^T \omega_K C_K \end{bmatrix}$$

ϕ : (3×3) matrix of zeros

From equation 1 of appendix D the matrix R_i is

$$R_i = C_i^T \omega_i C_i$$

Appendix H. Target Location Errors

Case II and Case III results are presented in this appendix. Tabular entries are 99 percent confidence sphere radii in meters specified by observational mode and by input error description. The integer values enclosed in parentheses in each of the titles pertain to observational mode. For example, (1, 1, 1) implies 3 Case III target trackers, while (2, 2) implies 2 Case II target trackers. Case II and Case III observational modes are defined below:

1. Case III

- a. Target coordinates measured in the focal plane of the target sensor.
- b. Target tracker position coordinates measured, for example, by GPS. In fact, the position errors are labeled GPS errors.
- c. Target tracker attitude coordinates measured, for example, by a Real-Time Attitude Sensor System. Attitude errors are labeled SIGA.
- d. Slant range distance to the target from the target tracker measured by a ranging device. Slant range errors are labeled SIGR.

2. Case II

All of the above except d.

The second set of numbers in the title defines the angular distance between adjacent target trackers with respect to the target. Note that when there is only one target tracker, then it must be a Case III observation and there is no angle description.

Values listed under the heading "DIST" pertain to slant range distances to the target from the target trackers. Multiply those values by 10^6 to express the slant range in meters.

Tabular entries are 99 percent confidence sphere radii. If other confidence sphere radii are required, then perform the appropriate calculation.

$$50\% \text{ Confidence Sphere Radii} = 0.4566 * S$$

$$90\% \text{ Confidence Sphere Radii} = 0.7423 * S$$

$$95\% \text{ Confidence Sphere Radii} = 0.8300 * S$$

where S is the 99% confidence value in meters.

Appendix I. Target Location Errors Derived from Range Observations Only

Tabular entries are 99 percent confidence sphere radii in meters derived from 3, 4, or 5 simultaneous range measurements. It is assumed here that a target tracker makes only slant range measurements (Case I) to the target. Errors are functions of target tracker position errors (in meters) listed under GPS. Errors are also functions of slant range errors (in meters) listed under SIGR. The angle ALPHA defines the angular distance between adjacent target trackers. Note that there are no results for ALPHA = 75 degrees in Table I-3. This is because adjacent angles in a pentagon-shaped model must be 72 degrees or less. Finally, the k-values pertain to the degree of correlation among target tracker positions as described in appendix E. Errors are not organized by distance to the target since target errors are independent of slant range in the range only mode of observation.

Tabular entries are 99 percent confidence sphere radii. If other confidence sphere radii are required, then perform the appropriate calculation.

$$50\% \text{ Confidence Sphere Radii} = 0.4566 * S$$

$$90\% \text{ Confidence Sphere Radii} = 0.7423 * S$$

$$95\% \text{ Confidence Sphere Radii} = 0.8300 * S$$

where S is the 99% confidence value in meters.
