19 ABSTRACT (Continue on reverse if necessary and identify by block number)					
The fluctuation analysis has been extended to study of liquid/liquid interface and of phospholipid bilayer membranes. These studies were done with a discrete amplifier as opposed to FETs used before. This technique allows to carry out impedance measurements approximately one decade below that normally used in AC impedance analysis. The representation of power spectra on logarithmic scale of frequencies without distortion has been developed. This is a new approach to digital filtering. Preliminary investigation of chemical modulation of work function of synthetic metals has been initiated. It has been shown that a rigorous control of electropolymerization conditions can produce materials of widely different work function.

- d. BRIEF

The main goal of this period was to develop the technique of equilibrium fluctuation analysis and to apply it to electrochemical problems. In the last year we have extended the fluctuation analysis to study of the liquid/liquid interface and of phospholipid bilayer membranes. These studies were done with a discrete amplifiers as opposed to FETs used before.

Approximately 15% of funds in this period were used to initiate research into chemical modulation of work function of synthetic metals results of which form the basis of our new proposal. The equilibrium fluctuation analysis will be heavily used in the next phase of our work.

e. SIGNIFICANT RESULTS

We have shown that equilibrium fluctuation analysis offers a fundamentally different approach to characterization of dynamic properties of various electrochemical systems ranging from fast redox couples, to liquid/liquid interface, bilayer membranes and even insulator/solution interface. This technique allows the study to be done under the conditions of true equilibrium. It is possible to carry out impedance measurements approximately one decade below that normally used in AC impedance analysis.

The representation of power spectra on logarithmic scale of frequencies without distortion has been developed. Because this is a new approach to digital filtering we have applied for a patent protection.

Chemical modulation of work function of new electronic

materials has been identified as an important factor which has to be considered in application of materials such as synthetic metals. Our preliminary study shows that a rigorous control of electropolymerization conditions can produce materials of widely different work function.

f. SUMMARY OF PLANS

The relationship between work function and conditions of electrochemical preparation of synthetic metals will be investigated. This will include the effect of the applied potential during the polymer growth as well as the ion exchange during the relaxation period. We will try to elucidate the mechanism of ion exchange (doping) using equilibrium fluctuation analysis developed during the previous period of this contract. This will also yield the value of resistivity of thin films under "wet" conditions. The principal technique for for assessment of the "quality" of these materials in all stages of their investigation will be the Kelvin probe. It is expected that this study will highlight the importance of WF as the key property for any electronic applications of these materials.
