Advanced Construction Technology Center
University of Illinois at Urbana-Champaign

The Advanced Construction Technology Center is a unit of the College of Engineering. It is administered by the Department of Civil Engineering. The Army Research Office provides core financial support under the Department of Defense-- University Research Initiative Program. The Center's multidisciplinary research program is conducted by the faculty and graduate students of the University of Illinois at Urbana-Champaign.

United States Army representatives to the Center include Dr. Fritz Oertel, Scientific Program Officer for the Army Research Office and the following other members of the U.S. Army Advisory Committee to the center.

> Dr. L.R. Shaffer. U.S. Army Construction Engineering Research Laboratory; Champaign, Illinois (Committee Chairman)

> Dr. Eugene Marvin, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire;

> Dr. Margaret E. Roylance, Composite Materials Technology Laboratory, Watertown, Massachusetts;

> Dr. Robert Storer, Naval Civil Engineering Laboratory, Port Hueneme, California;

> Dr. Lillian D. Wakeley, Waterways Experiment Station, Vicksburg, Mississippi;

> Dr. Guiliano D'Andrea, BNT Laboratory, Watervliet Arsenal, Watervliet, New York;

The Center Director is Professor Joseph P. Murtha, Newmark Civil Engineering Laboratory, University of Illinois, 205 North Mathews Street, Urbana, Illinois 61801, Phone (217) 333-6937

19. ABSTRACT (Continue on reverse if necessary and identify by block number)

The pedologic soil series is the basic mapping unit utilized by the U.S. Department of Agriculture Soil Conservation Service (SCS). Modern soil survey reports are available for many counties throughout the United States. Numerous studies have indicated that soil series is an appropriate procedure for characterizing the engineering properties of surficial soils. For example, the Illinois DOT Soil Manual is keyed to pedologic soil series. The U.S. Army Corps of Engineers CERL group has cooperated with the USDA SCS in developing versatile software programming to access the SCS SOI-5 and SOI-6 data bases which include detailed information on more than 16,000 soil series mapped in the U.S.A. The purpose of this project was to determine the feasibility of using pedologic soil series for estimating the resilient modulus (E_{Ri}) of fine-grained subgrade soils. Most large-scale construction projects cut across many different soil series and it would be helpful to have a quick and economical method for estimating subgrade moduli for pavement design or other horizontal construction related purposes.

INTRODUCTION

The development of horizontal facilities (highways, airfields, parking areas, etc) involves the consideration of large areas. Detailed soil explorations are normally not conducted to support the selection of subgrade soil inputs for pavement design.

The resilient behavior of a soil is an important property for pavement analysis and design. A commonly used measure of resilient response is the "resilient modulus", defined by:

$$E_R = \sigma_D / \varepsilon_r$$

where:

E_R: resilient modulus;

σ_D: repeated deviator stress;

ε_r: recoverable axial strain.

Repeated unconfined compression or triaxial testing procedures are often used to evaluate the resilient moduli of fine-grained soils and granular materials. Resilient moduli are stress dependent: fine-grained soils experience resilient modulus decreases with increasing stress, while granular materials stiffen with increasing stress level.

Thompson and Robnett (1) proposed an arithmetic model for describing the stress softening behavior of fine-grained soils. The model is shown in Figures 1 and 2. Extensive resilient laboratory testing, nondestructive pavement testing, and pavement analysis and design studies at the University of Illinois have indicated that the arithmetic model (Figure 2) is adequate for flexible pavement analysis and design activities.

In the arithmetic model, the value of the resilient modulus at the break-point in the bilinear curve, E_{Ri} (Figure 2), is a good indicator of a

soil's resilient behavior. The slope values, K_1 and K_2, display less variability and influence pavement structural response to a smaller degree than E_{Ri}. Thompson and Robnett (1) developed simplified procedures for estimating the resilient behavior of fine-grained soils based on soil classification, soil properties, and moisture content.

The pedologic soil series is the basic mapping unit utilized by the U.S. Department of Agriculture Soil Conservation Service (SCS). A soil series is also assigned a "number". For example "Flanagan" is soil series #154. Modern soil survey reports are available for many counties throughout the United States.

Numerous studies have indicated that soil series is an appropriate procedure for characterizing the engineering properties of surficial soils. For example, the Illinois DOT Soils Manual (2) is keyed to pedologic soil series. The U.S. Army Corps of Engineers CERL group (3) has cooperated with the USDA SCS in developing versatile software programming to access the SCS SOI-5 and SOI-6 data bases which include information on more than 16,000 soil series mapped in the U.S.A. It is easy to gain quick access to an extensive data base for any soil series.

The purpose of this project is to determine the feasibility of using pedologic soil series for estimating the resilient modulus (E_{Ri}) of fine-grained subgrade soils. Most large-scale construction projects cut across many different soil series and it would be helpful to have a quick and economical method for estimating subgrade moduli for pavement design or other horizontal construction related purposes.

The goal of this research is to establish a relation between soil series and subgrade modulus. If there is a strong relation, then the subgrade modulus values for design purposes could be obtained from readily available county soil reports and maps. Even if it is not possible to assign values

2

for subgrade modulus based on soil series information, it may be feasible to determine which areas warrant more intensive field testing. Identifying problem areas would allow for more efficient and cost effective field testing.

PROCEDURE

Thompson (4) has summarized University of Illinois procedures for predicting subgrade E_{Ri} based on 9-kip Falling Weight Deflectometer (FWD) pavement surface deflection data. The subgrade E_{Ri} algorithms (based on ILLI-PAVE generated data bases) for flexible pavements are:

<u>Surface Treatment and Granular Base</u>

$$E_{Ri} = 24.2 - 5.71 \, D3 + 0.35 \, D3^2 \tag{1}$$

<u>Asphalt Concrete Surface > 3 inches and Granular Base</u>

$$E_{Ri} = 25.0 - 5.25 \, D3 + 0.29 \, D3^2 \tag{2}$$

<u>Asphalt Concrete Surface and Granular Base</u>

$$E_{Ri} = 24.1 - 5.08 \, D3 + 0.28 \, D3^2 \tag{3}$$

<u>Full-Depth Asphalt Concrete</u>

$$E_{Ri} = 24.7 - 5.41 \, D3 + 0.31 \, D3^2 \tag{4}$$

where:

E_{Ri} - Subgrade resilient modulus, (ksi)

D3 - 9-kip FWD pavement surface deflection (mils) at 36 inch offset

The Illinois Department of Transportation conducted Falling Weight Deflectometer (FWD) tests on several two-lane road flexible pavements throughout the state of Illinois. The projects included many of the major

3

soil series that predominate in Illinois. Table 1 summarizes the soil series and their occurrence in Illinois. Note the coverage is about 49%.

Figure 3 shows the locations of the Illinois counties involved. The flexible pavements tested are listed below:

Bond County Highway 3

Edwards County: IL 15 (west of Albion)

Jersey County: Highway 9 and Highway 25

Livingston County: Ocoya Road

Marion County Highway 23

Mercer County Highway 16

Peoria County Highway 60

Perry County: County Highway 12; County Highway 21; and IL Highway 154

Piatt County Highway 5

Sangamon County: New City Road

Williamson County Highway 3

Tables 2 and 3 present pertinent data for each project. FWD tests (9-kip loading) were conducted in the outer wheel path at intervals ranging from 50 to 200 feet along the roadway. FWD test locations were "staggered" when the "other lane" was tested. The FWD test station location and a county soil map were used to group the FWD test results into "soil series segments." The road test sections included from 3 to 11 different soil series, with many soil series occurring more than once.

Subgrade moduli (E_{Ri}) were calculated using the appropriate FWD algorithm (Equation 1, 2, 3, or 4). The FWD test data were processed by a PC computer program which generated average subgrade E_{Ri} values for the particular set of data. In addition to the average E_{Ri} values, the

standard deviation, coefficient of variation, and E_{Ri} percentile distribution values were computed. A typical output is shown in Appendix A. The data were subdivided and the average E_{Ri} for each soil series segment was calculated. Individual sections were then recombined with other sections of the same soil series, and an average E_{Ri} was found for that soil series within a project. Results for the individual soil series segments and the project wide soil series averages are presented in Appendix B.

"F-tests" were used to determine if the average E_{Ri} values were different. A significance level of $\alpha = 0.05$ was checked. Several types of comparisons were made. The most basic was the comparison of soil series segments within a project. Similar soil series segments within a project were compared using the average E_{Ri} values, standard deviations and number of FWD tests in each segment. The results of these comparisons are shown in Appendix B.

The next level of comparison was among soil series segments from different projects. This was carried out on two levels. The first of these levels used the individual soil series segments from the various projects. The second level used the project-wide soil series averages as the basis of comparison. Results of the comparisons are presented in Appendices C and D respectively.

In all cases, an average E_{Ri} value for an individual segment was only used for comparison purposes if it contained three or more individual FWD tests. However, all soil series segments were used in determining the average E_{Ri} value for that soil series on a project-wide basis.

5

RESULTS

Many different soil series appeared within a project. The soil series that occurred are listed by project in Appendix B. The total number of individual soil series was 61. Multiple segments of the same soil series within a project occurred 55 times. Comparisons were made of these 55 individual occurrences.

For example, Williamson County had 8 Ava (#14) soil series segments along Highway 3. Of those 8, 6 had three or more FWD tests, and were eligible for comparison. The average E_{Ri}, standard deviation and number of samples for those 6 gave a calculated "F-value" of 0.55. This F-value is not significant at $\alpha = 0.05$. Thus, it is concluded that the E_{Ri} of the soil series segments are not significantly different.

Using this type of comparison, 39 of the 55 (71%) soil series did not show a significant difference at $\alpha = 0.05$. Sixteen of the 55 (29%) comparisons did indicate a significant difference in average E_{Ri} values. The comparisons with a significant difference are listed in Table 4.

The next comparison considered soil series segments which occurred in different projects. There were 22 soil series which occurred in more than one project. These soil series were compared on two different levels using the "F-test."

The first project-project comparison level was based on the average E_{Ri} values for each individual soil series segment in all the projects for a particular soil series. The summary of these data is shown in Appendix C. The data are divided by soil series. The individual segments are listed for the various projects. Out of the 22 soil series compared, eleven of them (50%) had no significant difference at $\alpha = 0.05$.

6

For the second comparison level the <u>project-wide</u> soil series averages were used. These values are summarized in Appendix D. They are also grouped together by soil series. Out of the 22 soil series which appeared in two or more projects, eleven of them (50%) had no significant difference at $\alpha - 0.05$.

To further investigate the differences among soil series segment E_{Ri} means showing a significant difference ($\alpha - 0.05$), "t-Test" based least significant difference (LSD) comparisons were made. The LSD comparisons identify those E_{Ri} averages that are significantly different. The LSD results are summarized in Appendix E. In most instances, many of the soil series segment E_{Ri} averages in the comparisons do not significantly differ.

In addition to the average soil series E_{Ri} values, the percentile distribution of E_{Ri} values making up the average is also of interest. The FWD data analysis PC program generates a percentile distribution table showing the "percent greater than" for ten increments of the E_{Ri} values. These distributions add to the interpretation of the average E_{Ri} values. For instance (see Appendix F), the average E_{Ri} value for Hoyleton soils in Bond county is 6.9 ksi. However, the distribution shows that 6.9 ksi falls at the 39 percentile. Thus 61% of the individual values for Hoyleton soils were lower than the average value of 6.9 ksi.

Appendix F summarizes data for the individual soil series' percentile distributions and average E_{Ri} values. Figures 4 and 5 show relations between 50 percentile and 85 percentile E_{Ri} and "average" E_{Ri} values, respectively. The average is approximately equal to the 50 percentile value and the 85 percentile value can be estimated from the average based on the regression equation shown in Figure 5. As would be expected (see Figure 6), the relation between the 100 percentile and average E_{Ri} value is not good. It is emphasized that the 100 percentile value is the <u>lowest</u> E_{Ri}.

7

Obviously, inconsistent and aberrant individual E_{Ri} values will control this low value.

The percentile distribution concept addresses a problem associated with the statistically based approach. For example, an average E_{Ri} value minus two standard deviations (approximately an 85 percentile value) can be negative. This is obviously not possible! The percentile distributions provide realistic lower limits and provide a better indication of typical E_{Ri} values.

Average E_{Ri} values for entire projects are also of interest. Table 5 presents these values. In each case, an average E_{Ri} value was found for the entire project based on the E_{Ri} for every individual soil series segment that had three or more FWD tests conducted. Standard deviation and coefficient of variation values were also calculated. The project average E_{Ri} values ranged from 3.1 ksi in Mercer County to 10.3 ksi in Marion County.

The "overall" average E_{Ri} value for all of the projects was 7.5 ksi with a standard deviation of 2.5. This average is based on the 255 individual soil series segments in the projects. Tabular and graphical presentations of the "overall E_{Ri}" percentile distribution are shown in Table 6 and Figure 7.

DISCUSSION AND COMMENTS

It is apparent that soil series can be used to characterize subgrade resilient moduli. No significant differences ($\alpha = 0.05$) were found in 71% of the "project level" comparisons. In soil series comparisons at the project-project level, no significant differences were noted in 50% of the cases. Table 4 and Appendix E indicate the comparisons where "statistically

8

significant diff   _s" were identified. Note that the "statistically

significant differences" are small. Figure 8 shows the distribution of the

soil series segments with LSD differences expressed as the average

E_{Ri}/Segment E_{Ri}. The boundary limits are shown at +/-20% of the average

E_{Ri}. A cumulative distribution representation of the data is shown in

Figure 9. A +/-20% E_{Ri} difference would translate to 1.5 ksi for a 7.5 ksi

E_{Ri} average.

The differences <u>are not of practical engineering importance</u> in pavement

design. Consider for example, that (wet of optimum) a 1% increase in

gravimetric moisture content will approximately <u>decrease</u> E_{Ri} as indicated

below (5).

USDA TEXTURAL CLASSIFICATION	E_{Ri} DECREASE/1% MOISTURE INCREASE (ksi/%)
clay, silty clay, and silty clay loam	0.7
silt loam	1.5
loam	2.1

9

SUMMARY

Soil series location information from modern county soil reports and maps (available from USDA Soil Conservation Service) can be correlated to subgrade soil resilient moduli (E_{Ri}) values back-calculated from falling weight deflectometer (FWD) surface deflection basin data. Data from over fifty miles of flexible pavements throughout Illinois are included in this study. The soil series included in the study account for approximately 49% of the surficial soils of Illinois. In 71 percent of the comparisons, there are not statistically significant differences in average subgrade moduli values for given soil series segments. When there is a statistically significant difference, it generally <u>is small and not of practical engineering importance</u> in a pavement design context.

The use of soil series - subgrade E_{Ri} data based on FWD studies can greatly expedite and simplify the establishment of subgrade E_{Ri} values for pavement analysis and design and similar types of horizontal construction activities. If data are not available for a particular soil series, soil series - E_{Ri} data can be easily developed.

APPENDIX A

TYPICAL FWD ANALYSIS OUTPUT

Appendix A is a sample output generated by the FWD data analysis
program. The output consists of a listing of the "normalized" FWD testing
data by station, and a statistical summary of the data. A percentile
distribution for the data is also shown. The example is for all of the
Bluford soil series segments in the Williamson County project.

APPENDIX B

PROJECT LEVEL ANALYSES

Appendix B presents FWD analysis data for each project. The data are the FWD test date, the number of the E_{Ri} regression equation used, the length of the project, and distance between test locations. The air temperature and the pavement surface temperature at the time of testing are also included.

The data are grouped according to soil series. Each soil series has an average E_{Ri} value, standard deviation, coefficient of variation and number of samples for that entire soil series. The same data are also included for each individual soil series segment with three or more samples.

An "F-value" for all soil series segments within the project is also included. This value indicates whether or not there is a significant difference at $\alpha =0.05$.

APPENDIX C

PROJECT-PROJECT ANALYSES

(Individual Soil Series Segment Approach)

Appendix C presents the average E_{Ri} values for those soil series occurring in _more than one_ project. The average E_{Ri} value for a given soil series is based on individual segments of that soil series. The standard deviation and coefficient of variation for each soil series are also included. Similar soil series segments are grouped together to show the data that were used to get the overall averages. The high and low E_{Ri} values are also indicated.

An "F-value" is also shown. Significant differences at $\alpha = 0.05$ are indicated.

APPENDIX D

PROJECT-PROJECT ANALYSES

(Project-Wide Average Approach)

Appendix D presents average E_{Ri} values for all of the soil series occurring in more than one project. The average E_{Ri} value for a given soil series is based on the project-wide averages from the individual projects. The standard deviation, coefficient of variation and number of samples are also included.

An "F-value" is also given. Significant differences at $\alpha = 0.05$ are also indicated.

APPENDIX E

LSD (LEAST SIGNIFICANT DIFFERENCE) COMPARISONS

Appendix E presents the results of the LSD tests conducted on the soil series which had a significant difference at $\alpha = 0.05$ with the "F-tests". The LSD tests identify those ranges within the data that are not statistically significantly different $\alpha = 0.05$. These ranges are underlined.

Note: All E_{Ri} data are ksi.

DISTRIBUTION LIST

This manuscript (ACTC Document #89-51-03) has been sent to the following persons and/or agencies.

Army Research Office, Library

U.S. Army Advisory Committee:
Dr. L.R. Shaffer, U.S. Army Construction Engineering Research Laboratory, Champaign, Illinois.
Dr. Fritz Oertel, U.S. Army Research Office, Research Triangle Park, North Carolina.
Dr. Gary L. Anderson, U.S. Army Research Office, Research Triangle Park, North Carolina.
Dr. Lillian D. Wakeley, Waterways Experiment Station, Vicksburg, Mississippi.
Dr. Eugene Marvin, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.
Dr. Robert Storer, Naval Civil Engineering Laboratory, Port Hueneme, California.
Dr. Giuliano D'Andrea, Bnt Laboratory, Watervliet, New York.
Dr. Margaret E. Roylance, Composite Materials Technology Laboratory, Watertown, Massachusetts.

Other
Jamie Florence, Manufacturing Technology Department of the Army, Warren, Michigan.
Mel Hironaka, Naval Civil Engineering Laboratory, Port Hueneme, California.
Dr. Jim Forrest, Naval Civil Engineering Laboratory, Port Hueneme, California.
Dr. Richard Berg, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.
Bob Eaton, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.
Vincent Janoo, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.
Karen Henry, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.
Edwin Chamberlain, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.
Wendy Allen, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, New Hampshire.
M. Kupperman, A. Epstein & Sons, International, Inc., Chicago, Illinois.
Professor Fred Moavenzadeh, Massachusetts Institute of Technology, Cambridge.
Mark E. Hollan, Naval Civil Engineering Laboratory, Port Hueneme, California.
Professor Lee Boyer, University of Illinois at Urbana-Champaign.
Professor John Melin, University of Illinois at Urbana-Champaign.
Professor Jim Lefter, University of Illinois at Urbana-Champaign.
