This report provides design and technical documentation on the Z-Grid Signal Processing System developed by the Electronic and Computer Development Laboratory, within the University of Dayton Research Institute. It was designed and fabricated as an analytical tool for structural testing and research on turbine components. This research effort was performed for the Aerospace Mechanics Group of the Research Institute. Michael Drake was the Principal Investigator and Robert Dominic was the Research Engineer in charge of daily activities for this project.

E&CD Lab personnel who contributed to this research and development effort were:

1. GENERAL DESCRIPTION

This document provides technical information on the Z-Grid Signal Processing System. The system is designed to process two frequency modulated waveforms. These waveforms are generated by the motion of a magnet mounted on the blade of the rotating turbine past two wire grid rings. The individual conductors of the two grids are insulated from each other and crossed orthogonally. The rotation of the blade produces variable phase differences between the two FM signals, dependent on the location of the magnet as it passes under the series of paired crossing conductors of the grid. The signal processing system processes this waveform and generates pulses corresponding to the peaks of the input waveform. Figure 1 shows sections of the system input and output waveforms.

The output pulses drive an LED for each of the two grid channels. The LEDs replace two of the fiber-optic bundles on the NSMS Data Acquisition System. The grid data is then acquired using the procedures described in the NSMS manuals. A general block diagram of the Z-Grid Signal Processing System is shown in Figure 2.

System input and output test cards are supplied and stored in the spare slots of the Z-Grid Signal Processor rack. Figure 3 shows the use of these cards in the system test mode. The test cards are for diagnostic and troubleshooting purposes, and should be used by qualified personnel only.

2. SYSTEM CONNECTIONS

The Z-Grid Signal Processing System is designed to be used in conjunction with the NSMS data acquisition system. The Z-Grid system provides its output using high intensity LED's which are substituted for the fiber-optic cables in the NSMS system. The only other connection required is a BNC cable from the grids to the preamplifiers for the Signal Conditioning System.

3. SYSTEM OPERATION

The Z-Grid Signal Processing System is designed to be transparent to the user of the NSMS System. All procedures for operating the system are identical to those described in the Turbine Blade Data Acquisition System User's Guide, with the following exception:

The number of blades (see WRDC-TR-87-2041, Page 5, section 9), must be equal to the number of crossings on the grid.

At the time of this writing, this number must be set to 36.

There are two adjustments on the Z-Grid Signal Processing System. These are the Preamp Level and the Time Delay adjustment. These should be adjusted when a new speed is used or the configuration of the system is changed (i.e. a new turbine, magnet or grid is installed on the system).

The Preamp Level must be adjusted for an output level between one-half and one volt. This is adjusted while the system is running at speed using pot R6 on the Preamp Board (Figure 7).

The Time Delay adjustment is determined by the setting of switches DS7 and DS8 on the Output Card (Figure 22). The Time Delay may be set based on either the turbine rotation speed or the desired time delay after the input pulse peak. Table 1 provides the information necessary for setting the delay.

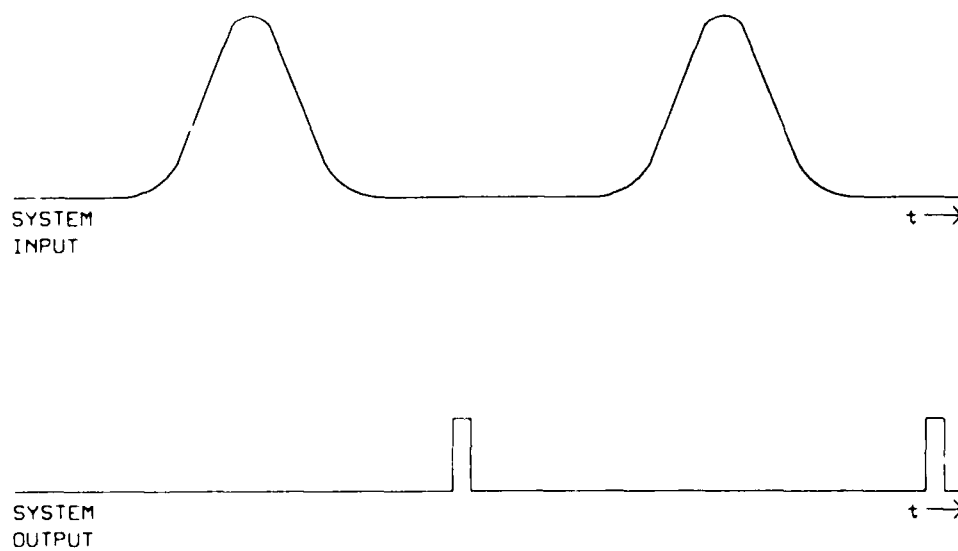

The first method of setting the delay is to set the switches based on a given turbine rotation speed. Using this method, locate the speed at which the turbine will be run in the "RPM" column of Table 1 and set switches DS7 and DS8 on the Output Card using the binary switch column of the table. Be sure to note the correct orientation of the MSB and LSB on the switches. Refer to Figure 22 for the location of the MSB and LSB.

The second method of setting the delay is to set the switches for a specific delay time. Choose a delay time from the "DELAY TIME" column on Table 1 and set the switches accordingly. The time delay is shown in Figure 4 as the Delay Time. The output pulse must fall within the period labeled WT on Figure 4, for correct system operation. It is important to insure that the delay time is not so short that the output pulse occurs during the pulse on the input waveform, nor so long that the output pulse occurs during the next pulse on the input waveform.

In addition to the two routine adjustments on the Z-Grid Signal Processing System, the characteristics of the digital filter can also be changed. This provision is included for reasons of system versatility. Table 2 lists the filter coefficients for use with different numbers of filter stages. The resulting filter characteristics are plotted in Figure 5. The filter coefficients **do not** require routine adjustment. The setting of the filter coefficients should not be attempted by unqualified personnel.

4. SYSTEM ELECTRONICS

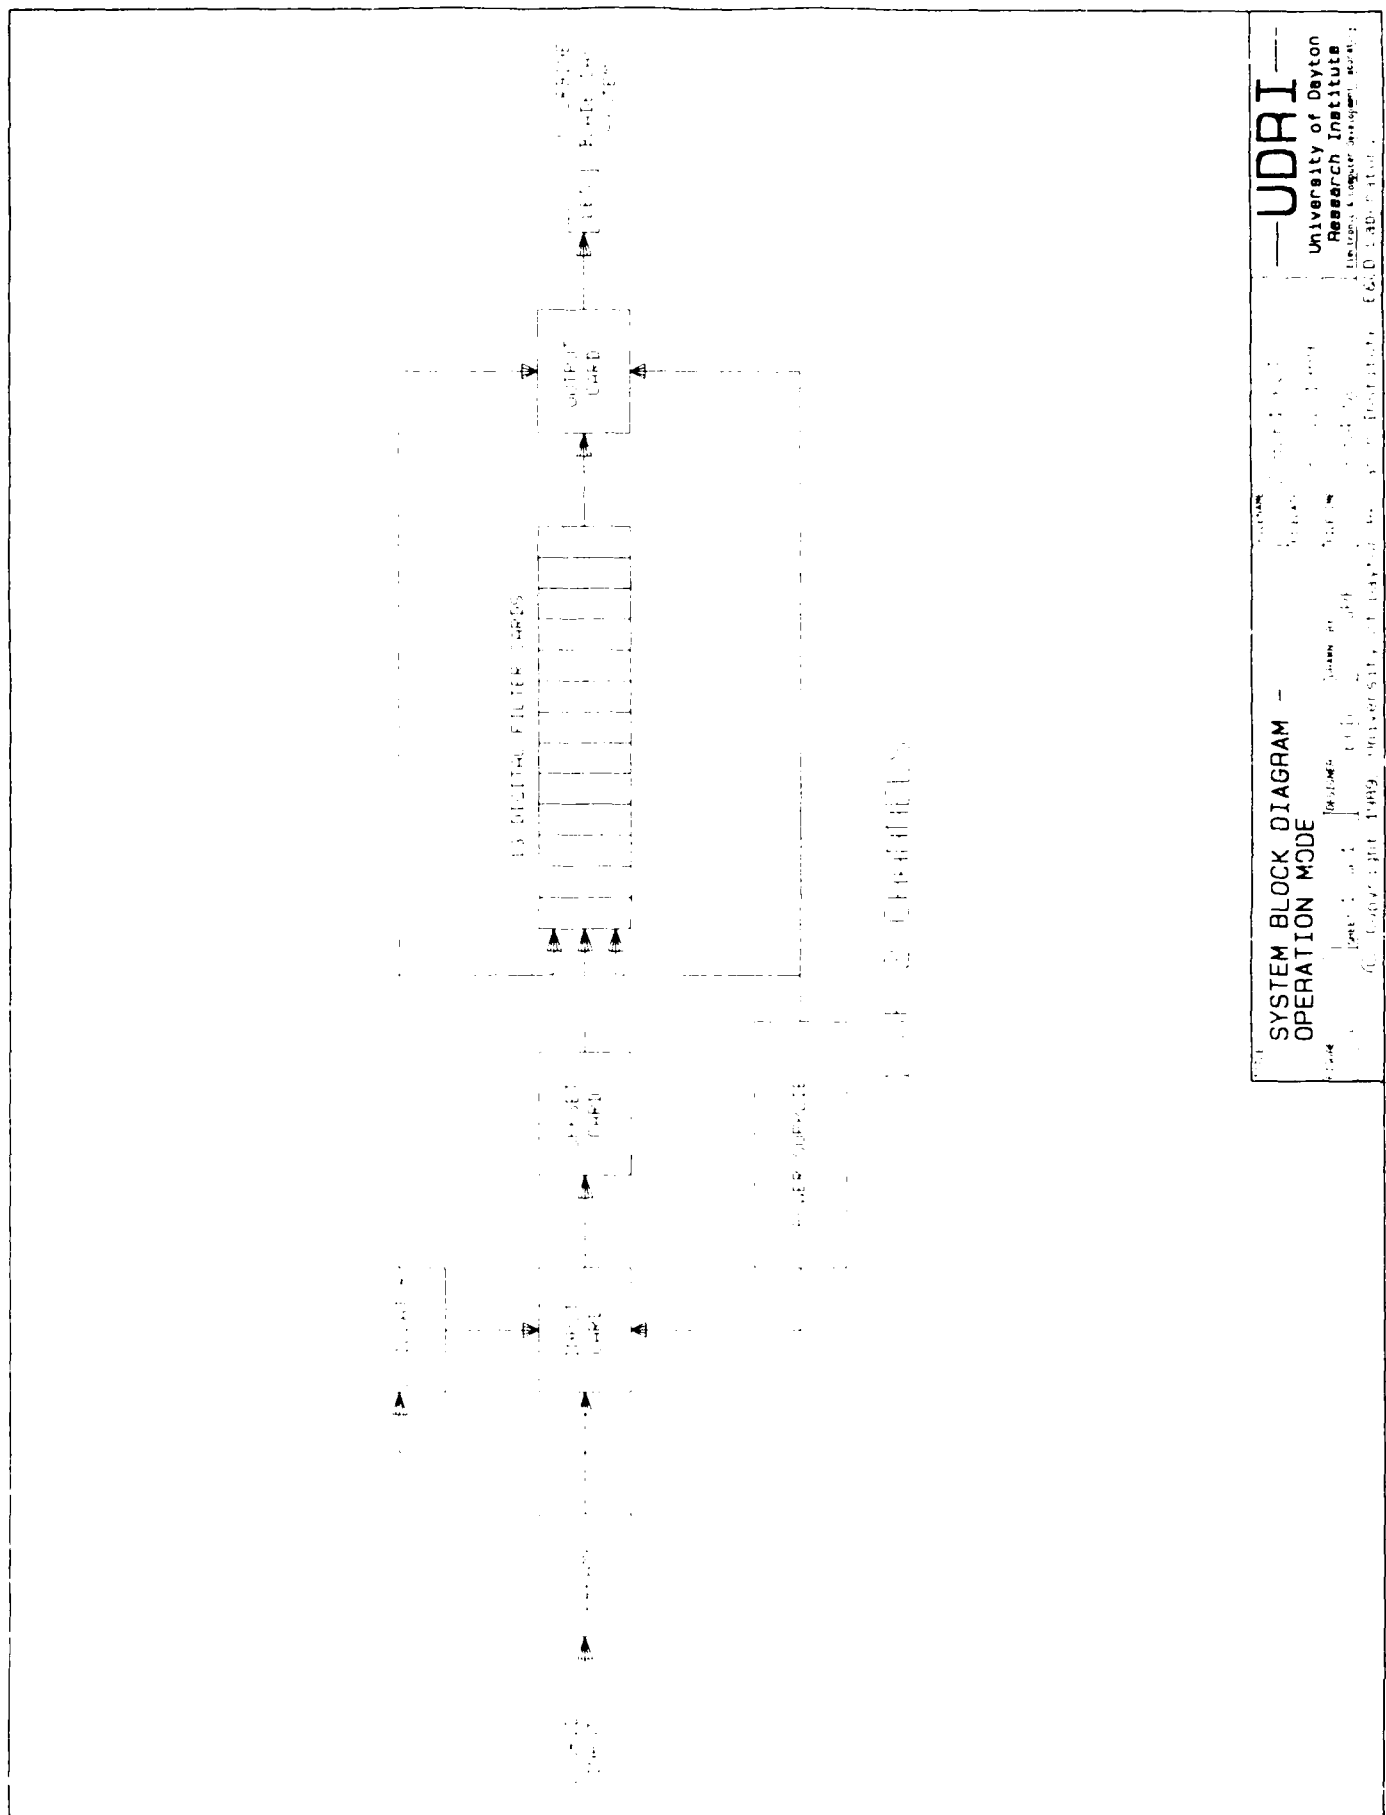

Figures 6a and 6b are an expanded version of the system block diagram in Figure 1. Figures 6a and 6b show the path of the input signal through the Signal Processor electronic circuitry. The circuitry consists of an external preamplifier, a Signal Processor rack with backplane-mounted, removable circuit cards, system test cards, and two output LEDs. The electronic circuitry for the Z-Grid Signal Processing System is documented in Figures 7 through 38. Parts lists for the circuit components are provided in Tables 3 through 11. The backplane pinout for the Signal Processing rack is listed in Table 12. This information is a technical reference provided for ease of repair or troubleshooting of the system by qualified personnel only.
