REPORT NO. NADC-89019-60

AD-A223 570

**WEIBULL PARAMETER CALCULATION AND  
WEIBULL MONTE CARLO ANALYSIS FOR  
ANALYZING PARTS FAILURES IN GAS  
TURBINES AND OTHER EQUIPMENT**

James L. Byers  
Air Vehicle and Crew Systems Technology Department (Code 6052)  
NAVAL AIR DEVELOPMENT CENTER  
Warminster, PA 18974-5000

29 JULY 1988

FINAL REPORT  
Task No. W13550000  
Project No. W135S  
Work Unit No. EM966  
Program Element No. 64268N

*Approved for Public Release; Distribution is Unlimited*

Prepared for  
NAVAL AIR SYSTEMS COMMAND (AIR-5360)  
Department of the Navy  
Washington, DC 20361-5360

90 07 2 062

## NOTICES

**REPORT NUMBERING SYSTEM** — The numbering of technical project reports issued by the Naval Air Development Center is arranged for specific identification purposes. Each number consists of the Center acronym, the calendar year in which the number was assigned, the sequence number of the report within the specific calendar year, and the official 2-digit correspondence code of the Command Officer or the Functional Department responsible for the report. For example: Report No. NADC-88020-60 indicates the twentieth Center report for the year 1988 and prepared by the Air Vehicle and Crew Systems Technology Department. The numerical codes are as follows:

| CODE | OFFICE OR DEPARTMENT                             |
|------|--------------------------------------------------|
| 00   | Commander, Naval Air Development Center          |
| 01   | Technical Director, Naval Air Development Center |
| 05   | Computer Department                              |
| 10   | AntiSubmarine Warfare Systems Department         |
| 20   | Tactical Air Systems Department                  |
| 30   | Warfare Systems Analysis Department              |
| 40   | Communication Navigation Technology Department   |
| 50   | Mission Avionics Technology Department           |
| 60   | Air Vehicle & Crew Systems Technology Department |
| 70   | Systems & Software Technology Department         |
| 80   | Engineering Support Group                        |
| 90   | Test & Evaluation Group                          |

| <p>A set of computer codes has been developed which can be used to analyze failure characteristics using a Weibull distribution. Included are codes for Weibull Parameter Calculation, Present Risk Analysis, Future Risk Analysis, Characteristic Life Calculation, and two Monte Carlo Failure Forecasting Codes providing both long and short printouts. When combined with Life Cycle Cost Analyses these codes will contribute to determination of rigorous return on investment for management decision making.</p> |       |                                                   |                                                                                                       |                                    |                                     |

## INTRODUCTION

The Naval Air Development Center (NAVAIRDEVCON) has developed a computer-based capability to estimate the lives of engine components. There exists a need to provide both rapid (first order) as well as more accurate estimates, therefore, an interactive conceptual design code, which operates on a desktop micro-computer, has been developed as LIFER, reference (a). This document describes the WEIBULL risk computational routine (WEIBER) which can be used alone, or as an integral part of the life estimation methodology. When combined with the Navy Life Cycle Cost Program, these codes will provide a true Return On Investment (ROI) capability. These codes provide the user with the capability to analytically establish trends with a high degree of confidence in their accuracy. Such results can be used for the many decision making requirements and can be presented to higher authorities for budget justification with a high degree of confidence.

There are numerous problems that can be addressed with these computer codes, such as: evaluating several options to fix fleet problems, minimizing operating costs, maximizing performance, deciding whether to increase the life of a part or buy more spare parts, etc. These computer codes represent the analytical tools required to make such evaluations, but they must be applied with care and good engineering judgment. Like any computer tool, they can be misused through careless input of incomplete or improper data. Throughout this and other reports describing these analytical tools there will be found cautions regarding the applicability of the tools and the necessity for as good and as complete a set of input data as possible. With the proper approach to the WEIBULL risk analysis referenced herein, almost any parts failure problem can be solved within the scope of the computer codes.

The code listings in the Basic language are given in the appendix. Most of these codes were originally developed on a Radio Shack Model 4 and in the version presented here they are directly usable on an ITT XTRA. This version has also been checked out on an IBM PC, an IBM PC-XT, an IBM PC-AT, a Tandy 1000, and a Zenith PC, using the identical disk and has been found to work perfectly. Past experience has shown that problem solution is enhanced and speeded up by making small changes to these codes as dictated by the individual problem. These changes are, for the most part, in the output format and not the calculation methodology. Several examples are referenced in this report.

## PROGRAM OVERVIEW

The Weibull Analysis Program is currently made up of fifteen codes, including the executive routine, "WEIBER", with its cover and introductory screens. These codes follow the general approach to Weibull analysis that is found in references (b) and (c) which outline the fundamental approach of the aircraft engine industry as represented by Pratt & Whitney and the General Electric Company. If at all possible, these references should be read in their entirety before using the codes of this report (WEIBER). References (d) through (g) were used to complete the understanding of general life prediction methods and make excellent reading for those interested in learning more about this area of reliability analysis.

The WEIBER executive routine code provides access to all other codes as well as the limited "HELP" routine. Currently, HELP only provides a concise description of the functions of each code and the input required to run each code. HELP also describes the output parameters that each code provides. The following paragraphs provide descriptions of all currently available codes.

**SUSWEIBL**, the Weibull parameter calculation code, is used to calculate the Weibull slope 'BETA' and the characteristic life 'ETA' using a statistical sample of data composed of both failures and suspended units (where suspended units are parts that are non-failed or not failed by the failure mode that is currently under consideration). Data required by the code are: (1) the total number of units in the sample population, (2) the number of failed units in the sample population, and (3) the quantity in, and age of, each group of units with the same age or operating time. The output from this code consists of: (1) BETA, (2) ETA, (3) B10 life, (4) B50 life, (5) least squares correlation coefficient, and (6) the instantaneous failure rate versus the age of the units. If BETA is known, or a good estimate is available, the option (6) code, 'ETACALC', could be used to calculate the characteristic life.

**PRESENT RISK**, the Present Risk Analysis code, is used to calculate the expected number of failures to have occurred to date over the current life of the units in the sample. The code is also useful for verifying the values of BETA and ETA by comparing answers obtained using this code with known failures in the population. Data required by the code are: (1) BETA, (2) ETA, and (3) the quantity in, and age of, each group of units with the same age. The output from this code consists of: (1) the percent in each group expected to fail,

(2) the number in each group expected to fail, and (3) the total number of expected failures for the population.

**FUTRISKS**, the future risk analysis code, is used to calculate the expected number of failures over a specified future time period for a population that accumulates more operating time over that time period. It is assumed that there are no repairs or new production so the failures are for the original population only and each part can fail only once. A more complex analysis, where parts are repaired and returned to service, is available in the Monte Carlo risk analyses, options 5, 6 and 11. Data required by the code are: (1) BETA, (2) ETA, (3) the number of months into the future that the analysis will cover, (4) the average monthly operating hours (or cycles or other time measurement) per part over the time period, and (5) the quantity in, and age of, each group of parts with the same age. The output from this code consists of: (1) the percent in each group expected to fail, (2) the number in each group expected to fail, (3) the cumulative count of failures, and (4) the total number of expected failures for the population.

**WEIBRISK**, a Monte Carlo Weibull failure analysis code, is used to forecast numbers of failures as well as the failure times in terms of operating hours or cycles. It is a complex code that makes thousands of calculations in each problem solution and keeps track of failures as they occur. The code also computes averages per iteration and per engine. It is extremely accurate when the correct Weibull parameter data is input and is capable of providing sensitivity analyses when precise Weibull data is difficult to obtain, such as early in an engine program when there have been few or no failures. Data required by the code are: (1) BETA, (2) ETA, (3) the quantity in, and age of, each group of parts with the same initial operating time, (4) the total number of units in the population, (5) the number of months into the future that the analysis will cover, (6) the average operating hours (or cycles, etc.) per month per part over the total time of the analysis, (7) the inspection interval at which, if reached before a failure occurs, all parts are made good-as-new or zero-timed, (8) the number of failure modes in the analysis, and (9) the engine name from which the parts come. Note that BETA and ETA must be furnished for each failure mode. It should also be noted that large numbers of parts and/or failure modes will greatly increase the running time (computer time). The output from this code consists of: (1) failure times, (2) running count of time on each engine, (3) subsequent failure time, (4) the number of failures per engine or part, (5) identification of the failure mode, (6) the average number of failures per engine or part per iteration, (7) the cumulative failures per engine, and (8) the average number of failures for all engines or parts over the total number of iterations. The number of iterations in the analysis can

be varied to any number desired. It is strongly suggested that a minimum of ten iterations be used.

**SHRTWEIB**, a Monte Carlo Weibull failure analysis code with a short printout, is a code that is almost identical to the previous code, WEIBRISK, except for the amount of hard copy output. In order to speed up the analysis, only numbers of failures are output while failure times by failure mode are suppressed. This code is very useful for the case where the dominant failure mode has been determined and the primary concern is the number of failures. It is also useful when time is critical and the calculation of the number of failures will allow some initial decisions to be made. With this code, many more engines or parts may be analyzed in a given amount of computer time relative to WEIBRISK and the amount of paper output generated is significantly less.

**ETACALC** is a code to calculate the characteristic life ETA when BETA is known for the failure mode and based on a statistically valid number of failures. Very accurate failure data is required to result in an accurate calculation of ETA using this code. Data required by this code are: (1) BETA, (2) the total number of failures for which data is available, and (3) data pairs consisting of the number of failures and operating times at the failure(s). The output from this code is the calculated value of the characteristic life, ETA.

**CNFINTBE** is a code to calculate upper and lower confidence bounds for both Beta and Eta as well as time to first failure. These calculations can be made for confidence levels of 0.90, 0.95, or 0.99. These upper and lower limits are indications of the accuracy one can expect from the many calculations that can be made from these codes. As higher values of confidence levels are chosen, the upper and lower bounds move farther apart.

**RELIABTY**. This code is used to calculate the reliability of a part at any time based on the values of Beta and Eta. The confidence interval may then be calculated for the value of reliability at confidence levels of 0.9, 0.95, and 0.99. The probability of failure is also presented. As in the case of the previous code, the upper and lower bounds move farther apart as the confidence level is chosen to be a higher value.

**BETARIST**. This code prints a hard copy of a list of probable values (or ranges of values in some cases) of the Weibull slope Beta for some common failure modes in gas turbine components or parts. While these historical trend values should not be taken to be absolute, they represent reasonable starting values, especially for performing sensitivity or "what-if" analyses.

**PWAWEIBL.** This code is similar to the SUSWEIBL code, number 1, except that it can provide the values of Beta and Eta which maximize the 'likelihood' of obtaining the observed data. There may be cases where these values may differ from those obtained in code number 1 or other codes that may be available. In most cases, however, they are close enough to not impact the final results to a great degree. If there is a concern over accuracy it is recommended that the data be run through both codes to establish sensitivities.

**BIGWEIBL.** This code is especially designed to handle up to 1100+ parts in a Monte Carlo analysis. It has been optimized for large numbers of parts and should be used only after the dominant failure mode has been determined. No more than one failure mode should be analyzed at one time when the quantity of parts nears the maximum since the memory available to the basic language will most likely be exceeded. The input is the same as for the previously described WEIBRISK and SHRTWEIB Monte Carlo analyses, (4) and (5), but the output is limited to that of code (5). Only the total failures are given per iteration along with the averages.

**WEIBAYES.** This code is for use when there is insufficient failure data to calculate the Weibull slope Beta and the characteristic life Eta with codes (1) or (10). This code requires that a best estimate be made of the failure mode and hence the Weibull slope Beta. The BETAHIST code (9) should be used for guidance as necessary. It is also required that the characteristic life be known or estimated using the ETACALC code (6) which is the true Weibayes estimate of 'ETA'. These values form the input for this code which then calculates the appropriate life of the part in question.

**ZOFALSB.** This code calculates the number of engines/parts that must be tested without failure in order to demonstrate that a given failure mode has been either eliminated or substantially improved. Inputs required are (1) Weibull slope Beta, (2) characteristic life Eta, and (3) an estimate of a reasonable amount of test time, recognizing that at least three parts or more must each be tested for that amount of time. The code allows a second and third test time estimate to be made (or more if necessary) and also provides for an alternate method of test plan formulation. The test plan is output in terms of a sample size, each of which must be tested for a given number of hours (or cycles) without failure in order to demonstrate a significant improvement in life.

**NZFTSTP.** This code is similar to the previous code except that it calculates a test plan that allows for

failures. Here the goal is to devise a test plan to demonstrate the achievement of a given improvement in a part's characteristic life. The test is passed if all parts are run for a specified number of test hours (or cycles) with no more than the calculated number of failures. Input consists of (1) the current characteristic life, (2) the characteristic life with an improved part or fix, (3) the Weibull slope BETA for the failure mode, and (4) a reasonable estimate of test hours for each test article. Output consists of a sample size, the number of test hours for each part in the sample, and the number of failures allowed for a successful test.

## PROGRAM DESCRIPTION AND OPERATION

### PROGRAM WEIBER

WEIBER is the WEIBULL Executive Routine which provides access to all other codes and the HELP routine. This code is entirely interactive and menu driven. When WEIBER is first activated, those familiar with its operation can go right to the desired code to calculate the parameters of interest. Those with less familiarity should choose the menu or HELP. Choosing the menu still allows one to go to help if desired, directly from the menu. The menu gives the user the choice of selecting any of the options by name and number. An option is chosen by inputting the option number. The chosen code next appears with instructions on how to proceed. Always be sure to follow instructions explicitly because format is critical for most input.

There are currently fourteen options available with room for four more. Future codes which are being considered at the present are those to utilize Weibull "Thorndike" charts, treat shifting Weibulls, and account for curved Weibulls. In addition, data bases for Weibull parameters will be established as the codes are used for solving more and more problems. These and other options will be added as they become necessary in the ongoing process of analysis. The current fourteen options will be described in more detail and sample solutions will be presented to illustrate their fundamental capability. Some of the options exist in several versions other than those presented. These other versions were generated for special case analyses and will not be presented here since they are not general enough to be of wide interest.

1. SUSWEIBL is the SUSPENDED WEIBULL code which is used to calculate values of the Weibull slope (BETA) and the characteristic life (ETA). Actual failure data is used as well as data from parts in the population which have not failed, or have failed in another failure mode. For

example, consider a population of six turbine disks which have all been tested to failure. Figure 1 shows the first screen of the SUSWEIBI code which asks for the input data. First, the total number in the sample is required, along with the number that have failed. Secondly, the distribution of failures is required. This data is input in the format of data statements and requires line numbers for the BASIC code. Figure 2 is a sample of such an input. Note that in each case there is a line number followed by the requested data. The exact line number as shown must be used. All computers have limits for the length of data lines so more lines may be needed. Use consecutive line numbers if more lines are required, starting with 8911 and not exceeding 9000. As currently configured, only ten data pairs can be entered. To enter more than ten data pairs, add dimension statements as follows in lines 150 and 151:

```
150 DIM T(100)
151 DIM F(100)
```

This will allow a total of 100 data pairs to be used.

Note that the values F1, F2, F3, etc., are the cumulative count of the failures and that there must be as many values as the number K entered in line 8800. The cumulative count data are always entered as increasing numbers which are consecutive. See line 8910 in figure 2. In cases where the entire population has NOT failed there will be suspended data. For example, there may have been only five failures out of the population of six. In the illustrated case of Figure 2, this may have been the disk with 950 hours, or disk number 4. The data line would then be:

```
8910 DATA 780,1,820,2,910,3,1050,5,1050,6
```

Note that the fourth disk with 950 hours has been omitted, or suspended, but that everything else is the same as in figure 2. The values of Beta and Eta will be slightly different for five out of six failures than for all six failing, as they should be. Always enter the data in ascending order of age to failure, omitting unfailed parts or parts failed in other failure modes. This same data is used to create a histogram of failures.

The sample solution presented later in this document shows a sample of the output screens using an input of six out of six failures. If a Weibull plot is desired it may be plotted using the data presented (Cumulative Percent Failed versus Time to Failure). Also shown on the screens are Beta, Eta, B10 and B50 lives, and the least squares correlation coefficient. The Weibull parameters may be verified by plotting the Weibull data and graphically determining the same values. Additional data shown on the

last screen is the value of the instantaneous failure rate versus the age of the parts. Note that all of the above output values will change if either more or fewer than six failures are used.

2. **PRESRISK** is the PRESent RISK analysis code which is used to calculate the number of units that should have failed by the present time, or, the expected failures to date based on the current operating times. This code is very useful in verifying the values of Beta and Eta that are used, knowing the actual number of failures to date and comparing them with the calculated number of failures. Figure 3 shows the first screen of the PRESRISK code which asks for the input data. The first data required are the values of Beta and Eta for the given failure mode. This input is entered as a data statement and therefore requires a line number (4000). The next input are data pairs consisting of the number of parts that all have the same current operating time and the value of that common operating time. These data are also entered as a data statement using the line number 4040. Again, as many data pairs as necessary should be used as long as it is consistent with the line length allowed by the computer being used. The current code allows for ten data pairs but this may be increased by adding dimension statements as in SUSWEIBL. For example:

```
12 DIM N(100)
13 DIM T(100)
```

This will allow a total of 100 data pairs to be used. Figure 4 is a sample of such input and consists of five data pairs representing a total of twenty-five parts. It can be seen that there are five categories of operating time and that there are five parts in each time category. Additional data pairs can be input by using additional DATA lines starting with program line 4041 and not exceeding line 4999. Note that data is entered in ascending order of operating time.

Data pairs should be formulated such that the distribution represented by all the data pairs is a good representation of the real life distribution. There can be as many as one data pair for every part, but this usually becomes unwieldy when there are many parts to be considered. It is not necessary for the data pairs to represent exact multiples of the same size, such as 5, 10, 20, 100, or 1000. The number of parts in each data pair can be the same or each one can be entirely different and completely independent. The distribution should be as representative and complete as possible to yield the most accurate results.

The last input data is that of figure 5. Inputting the number of data pairs entered is necessary for the code to

FIGURE 6 PRESRISK OUTPUT SCREEN

properly account for all data pairs. This number is used in a counting loop to assure all failures are calculated.

The output screen is shown in figure 6. In addition to giving the number of failures for each data pair, the total failures are given for all data pairs. Also, the inputs are presented such that a record is available to identify the case analyzed. The current PRESRISK code automatically gives a hard copy printout that duplicates the output screen. This can be suppressed by eliminating all lines in the code that start with LPRINT. It is NOT recommended that this be done except when a printer is not available or when the available printer is not working. In such cases the code will hang up if the LPRINT instructions are not eliminated. Do NOT save the code with the deleted LPRINT lines using the same name (PRESRISK) or the hard copy version will be lost.

3. FUTRISKS is the FUTure RISKS analysis code which is used to calculate the expected number of failures over the next user defined time period, such as 12, 15, 30, or 36 months. This future time period is always specified in months and may be any value as required. Only one failure mode can be examined at a time but the code runs very fast and can be repeated as many times as necessary to cover as many failure modes as one desires in a very short period of time. Figure 7 shows the first screen of FUTRISKS which requests the input data. The first data items to be input are BETA and ETA for the failure mode of interest, just as in the previous code, PRESRISK. Again, this is entered as a data statement and requires a line number, which in this case is 4000. The next input required is the number of months into the future that the analysis is to cover, along with the average utilization rate in operating hours per month. These input data items are separated by a comma as are BETA and ETA. Note that cycles, time at maximum power, time at specified temperature, afterburner lights, or any other age measurement may be used in place of operating hours as long as BETA and ETA are determined using the same parameter.

The last data to be input are data pairs consisting of current operating time (or cycles, etc.) preceded by the number of units or parts having the same operating time. Again, all values are separated by commas. As many data pairs as necessary may be entered but it should be kept in mind that, as the number of data pairs grow, the computing time lengthens. While the computation time lengthens, the computer code is still relatively fast with large numbers of data pairs. There is currently a limit of 41 data pairs in the code. If more data pairs are to be used, change the existing dimension statements to the number desired. For example:

FIGURE 8 FUTRISKS INPUT SAMPLE

```

290 DIM N(100)
300 DIM T(100)

```

These changes will allow a total of up to 100 data pairs to be input. One can always input fewer data pairs than allowed by the dimension statements, but never more. Figure 8 is a sample of the input required by FUTRISKS and consists of 14 data pairs representing 2052 parts. Note that the operating times are equally divided into increments of 100 with an initial value of 50 hours. At times of 1750 and 1950 the number of parts are 0 (zero). This is an indication that the input was derived from a distribution of average numbers of parts versus operating time, or a histogram. Note that the data is entered in ascending order of operating time. Data pairs for FUTRISKS should be as accurate as possible and obviously as complete as possible. If there are zero parts for a given class interval (time period) of operating time, then a zero should be entered and it should count as a data pair. Since the last input is the number of data pairs it is important to count all data pairs, even those with zero parts.

The output screen is shown in figure 9. In this figure the first and second columns are the numbers of parts and the operating time at the end of the future time of the analysis. These are data pairs corresponding to the future time for which the number of failures is desired. The third and fourth columns are the percent failure for each future time data pair and the corresponding number of failures. The last column has the cumulative number of failures for each future data pair. The last item shown is the total number of expected failures for the total population over the total accumulated operating time of the analysis. The current FUTRISKS code automatically gives a hard copy printout that duplicates the output screen. This can be suppressed by eliminating all lines in the code that start with LPRINT. It is recommended that this NOT be done unless there is no printer available. In no case should one save the code with deleted LPRINT lines on the original disk using the same name (FUTRISKS) or the hard copy version will be lost.

4. **WEIBRISK** is the most comprehensive of all the codes available through WEIBER. It is a completely automatic code to calculate the results of a Monte Carlo analysis; it can produce a very substantial amount of output. Use of this code can easily exceed the memory capacity (RAM) of microcomputers with 64K or less available to BASIC. If such is the case, the problem must be broken up into smaller parts, each part must be run separately, and the results then combined to form the overall result. The code is used to forecast the number of failures as well as the time for each failure. Problems can be solved with multiple failure modes where the analysis must determine the mode of failure

TOTAL FAILURES = 367.2732

FIGURE 9 FUTRISKS OUTPUT SCREEN

that causes each failure. This is done over an extended future time and is always accomplished a number of times in order to fulfill the requirements of the Monte Carlo analysis, generally 10 times or more. It is important to recognize that the analytical procedure will calculate the time to failure for all failure modes and then select the one with the shortest time to failure as the mode of failure. This is done for all engines until the total specified future time has been covered. At failure, the engine is assumed to have all modes of failure brought to zero time (good-as-new) by either replacing the part or by inspection and certification that the part will be suitable until the next inspection is due.

A typical problem could involve as many as 20 or more engines with 4 or more failure modes and with an analytical time period running as long as ten to twenty years, operating at an average of 25 to 60 hours per month. Such an analysis, performed ten times, would involve many thousands of calculations and mean keeping track of possibly hundreds of failures. It requires calculating the time to fail for each failure mode, determining which is the first mode to cause failure, and then recalculating the failures until the specified future time has elapsed. This would be done at least ten times for each engine until reasonable statistical averages can be determined.

Figures 10 and 11 show the first two screens which are introductory in that they tell what capability the code has, the required inputs, and the necessity of using the correct input format. Figure 12 is the first input screen and requests the input of BETA's for all failure modes. Also shown is a sample line input for BETA so there is no question about format. The next screen is the input for ETA's, figure 13, which also shows a sample line of input for clarity. The next input screen, figure 14, is for data pairs consisting of the number of engines with the least number of initial operating hours followed by a comma and then the corresponding number of operating hours. This data pair is followed by a comma and the next data pair of engines having the next least number of operating hours, a comma, and then that corresponding number of operating hours, and so on until all engines have been accounted for along with their initial operating times. If the initial time is zero for any engines then a zero must be input for that engine or group of engines. Again, a sample line is shown for clarification.

The next input screen, figure 15, is a series of input questions which must be answered with numbers. Items requested are: the number of data pairs entered, the total number of engines, the number of months the analysis is to cover, the average utilization rate (in flight hours per month) of the engines, the inspection interval (or maximum

WEIBULL RISK  
A MONTE CARLO SIMULATION

THIS PROGRAM PROVIDES THE CAPABILITY TO CALCULATE THE NUMBER OF FAILURES FOR SEVERAL DIFFERENT PARTS IN AN ENGINE OVER A USER SPECIFIED TIME PERIOD. UP TO 25 ENGINES CAN BE ANALYZED WITH SCHEDULED INSPECTIONS WHERE THE PARTS CONSIDERED ARE BROUGHT TO ZERO-TIME, i.e. ARE MADE GOOD-AS-NEW.

INPUTS CONSIST OF: NUMBER OF ENGINES; TIME SINCE LAST INSPECTION; ANALYTICAL TIME PERIOD; FLIGHT HOUR UTILIZATION RATE; TIME BETWEEN INSPECTIONS, INITIAL TIME ON ENGINES; WEIBULL PARAMETERS (BETA & ETA); and ENGINE DESIGNATION.

OUTPUT CONSISTS OF: TOTAL ENGINE FLIGHT HOURS; CUMULATIVE FLIGHT HOURS; TIME TO FAIL FOR EACH MODE; and TOTAL NUMBER OF FAILURES BY ITERATION.

FIGURE 15 WEIBRISK INPUT SAMPLE SCREEN 4

operating time), the number of failure modes input, and the engine designation. All of these are important in that they serve as counting limits or analysis boundaries. It is important to understand that if no failure occurs before any engine accumulates the number of operating hours equal to the inspection interval, that engine is assumed to be inspected and either repaired or certified as capable of going another inspection interval in operating hours. In other words, the engine is zero-timed (or equivalently certified) with regard to the failure modes of the analysis. For the next increment of operating time the engine is starting out at zero time regardless of whether it has failed and been repaired or has been inspected and certified capable of reaching the next inspection without failure.

Figures 16 through 18 are the series of output screens. The first data shown are the inputs such that the output can always be identified with regard to the specific case run. Following this initial output is the data for each engine grouped by iteration number. In this case ten iterations were run but only the first three are presented. The time to failure is given for each failure mode and all failure times are compared to the inspection interval. If one or more of the failure times are less than the inspection interval, then there is an indication of a failure. Otherwise the indication is for no failure and the engine goes to inspection. If there were one or more failures the lowest number of operating hours, or first failure time, is chosen to be the current failure time of the engine. If there is no failure then the operating time of the engine is taken to be the inspection interval. The code accounts for initial time when it makes its first calculations on an engine and then keeps track of operating time as it accumulates, up to the total time of the analysis. From the second calculation on, the new current time will be the old current time incremented by the time to first failure or the inspection interval, whichever is appropriate. Failures are accounted for and a running total is maintained for each iteration as well as for each engine in each iteration. Unfortunately, the number of failures in each failure mode is lost in the sorting process for determining the first, or lowest, time to failure. It is possible to read the hard copy output and to determine the number of failures attributable to each failure mode.

Generally, a total of at least ten iterations will be run and averages calculated. The number of iterations should be checked, at least initially, since the code may have been furnished with a sample case that is fixed at three iterations. This is so that the sample will run reasonably fast for illustrative purposes. The averages presented in the output are: the average number of failures per iteration and the average number of failures per engine per iteration. Also presented is

the total number of failures for each iteration. Until the number of failures per failure mode is added, one can always go back over the hard copy output and determine which failure mode is responsible for each failure. Unless there are a vast number of engines analyzed over a very long time period, this manual effort is relatively simple and fast. It is, however, readily apparent that there is a great deal of data generated by this code, even when there are only a few engines and a few failure modes.

5. **SHRTWEIB** and its variations are reduced output versions of WEIBRISK for use where there are many engines and several failure modes. While all the calculations and concepts of the Monte Carlo analysis are exactly the same, the amount of data output is greatly reduced. Since the output is reduced, the flexibility is also reduced. If there are many engines involved, say 250 engines and multiple failure modes, it is likely that one would be interested in first knowing the number of failures to expect. If this is the case then this is the code to use since almost all of the output is suppressed and only the final tabulations of averages and total failures is output. If there is a need for failure modes identification and failure times, it is possible to output all these values while omitting most of the explanatory words normally output by WEIBRISK. This is done by adding PRINT or LPRINT statements to the BASIC program as required by the desired data to be output.

The input screens are identical to those of WEIBRISK and will not be repeated here. The output screens are very limited. Figures 19 and 20 illustrate a case in which failure times and failure modes are not required. These figures show the SHRTWEIB output screens for the same case as show for WEIBRISK (figures 16 through 18). Only the summaries of each data pair are shown in the output, along with the input data to be sure that the particular case can be identified. The totals are kept per iteration as in WEIBRISK and the summary at the end is exactly the same as the WEIBRISK summary.

This code has been used in many different versions, each one adjusted for a particular problem application. SHRTWEIB is basically a short version of WEIBRISK and is virtually identical except for the output format. Knowing this, it is easy to see why there can be so many variations, each one called SHRTWEIB. Currently there are two main versions, SHTWEIB1 and SHTWEIB2. Only one has been presented here in the interest of brevity and because it is so simple to make any necessary change in output format. Anyone with a fundamental knowledge of the Basic language could make the necessary modifications to SHRTWEIB to fit a specific problem. Keep in mind that it may be more prudent

to modify WEIBRISK if the final configuration will be closer to that output.

6. ETACALC is a short code which will calculate the characteristic life (ETA) when the value of BETA is known or the failure mode is known and a 'good approximation' of BETA is available. Figure 21 is the input screen which first calls for BETA and then the number of failures for which failure data is available. Such data makes up the next line of input and consists of alternate values of the number of non-failed parts in the sample and the operating time on these parts. Again, this is data from a histogram of the sample population. If there were no failures, the value of 'T' should be input as one (1). This assumes that there is a failure imminent and therefore gives a conservative, or lower, value of ETA. Zero cannot be used since it would result in a 'division by zero' error. It is also required to input the number of data pairs entered for use as a counting reference.

For reference purposes, the output screen of figure 22 presents the data pairs entered and used as well as the calculated value of ETA. The value of BETA used in the calculation is also presented. This code runs very fast and is extremely useful in calculating the sensitivity of ETA against the value of BETA or the number of failures. For each value of BETA input there will be a different value of ETA. If the failure mode is known one can be reasonably sure that BETA will fall between the limits that are historically typical for that failure mode. For example, low cycle fatigue historically has a value for BETA that lies between 2 and 5. While there are no guaranteed values or ranges, there are historical trends that are reasonable starting points when there is a lack of detail about specific failures.

7. CNFINTBE & CNFINTFE are two codes that have been grouped together for convenience. The first code calculates the confidence interval, or range of expected values, for both Beta and Eta. The user chooses the confidence level (0.90, 0.95, or 0.99) desired as well as the values of Beta and Eta. These are input in response to specific prompts on the screen. The last prompt asks for the number of failures that were used to calculate these values of Beta and Eta. Figure 23 shows the input for this code. Finally, the ranges of expected values of these parameters are given and are shown in figure 24 along with the input values and the chosen confidence level. These ranges, or confidence intervals, are measurements of precision in estimating the parameters. The confidence interval almost always contains the input value of the parameter and the magnitude of the range is an indication of how far from the true value an estimate of Beta or Eta might deviate. Strictly speaking, this methodology applies only to the case where all units or

parts in a particular sample have been test or run to failure.

The next option asks if the user would like to calculate the confidence interval for the time to first failure. Choosing this option automatically loads the appropriate code without returning to the Weibull Executive Routine (WEIBER). Here you are asked for all the same type of input as before (Beta, Eta, and number of failures) as well as the estimated or calculated value of time to first failure. The input screen is shown in figure 25. As in the previous case, the range of expected values for time to first failure is given and for record purposes the estimated value. Again, this range is a measure of the precision in estimating the time to first failure and is presented at a ninety percent confidence level. In this case the ninety percent confidence level is constant and is not user selectable.

8. RELIABTY & CNFINREL are two codes which are grouped together for convenience as were the previous two codes. The first code (RELIABTY) calculates the reliability at any given time. The required input is given at screen prompts and consists of Beta, Eta and the time at which the reliability is desired. These are shown in figure 26. The output consists of the reliability, the probability of failure, and the time at which they were calculated. The output is shown in figure 27. As in the previous two codes, the user is queried whether it is desired to calculate the confidence interval for reliability. If the answer is yes (Y) the next code (CNFINREL) is automatically loaded so that calculations can be made and the results presented on the screen as well as on the printer for record purposes. Input data are similar: (1) Beta, (2) Eta, (3) time at which reliability is calculated, and (4) the number of failures that Beta and Eta are based on. The input is shown in figure 28. The confidence level is also selected from 0.90, 0.95, or 0.99. These codes are grouped together and run in a similar manner as the previous two codes.

9. BETAHIST is a code which automatically provides a hard copy of reference values of Beta for various modes of failure. It is for use where there is insufficient data to calculate Beta from actual failures, either through code number one or graphically. This code is intended to be constantly updated and to be a comprehensive data base in the future. A copy of the hard copy printout is shown as Figure 29.

10. PWWEIBL is a code that has essentially the same functions as SUSWEIBL (code number one), plus the capability of determining the maximum likelihood values of Beta and Eta. The maximum likelihood values of Beta and Eta are those values which maximize the 'likelihood' of obtaining

\* A SLOPE GREATER THAN ABOUT 4.5 ARE USUALLY RAPID WEAROUT (BRICK WALL).

FIGURE 29      BETAHIST OUTPUT SCREEN

the observed data. They are mathematically most likely to yield the failure data used to 'calculate' Beta and Eta. The code also allows the input of a histogram or failure and suspended data, whichever is available and more accurate or complete. The code gives the same output as the SUSWEIBL code, except that there are no instantaneous failure rate data or B10/B50 lives presented. If all of this data is desired it is recommended that both codes be run to obtain the desired answers as well as to compare the common values obtained. Be sure that the input data is the same and the same number of failures are used. Input and out put screens are shown as figures 30 through 33.

11. BIGWEIBL is another version of the previously described Monte Carlo analysis. This version was specifically optimized to run a maximum number of units or parts failing under a single failure mode. This code should be used only after the dominant failure mode has been determined by using code four (WEIBRISK). The purpose of this code is to determine how many failures to expect over an extended period of time, such as five to ten years, out of a fleet of up to 1100 or more engines. The input is the same as for the WEIBRISK and SHRTWEIB codes (four and five) and the output is the same as in SHRTWEIB (code five) - total failures and averages. It is very important to input data correctly and accurately since the code requires an extended time to run when the number of parts or engines approaches the maximum of over 1100. Typically on an ITT-XTRA it takes about forty-five minutes to run 1149 engines, ten years, sixty hours per month, and to make a total of ten iterations. Since the input is identical with the previous Monte Carlo codes and the output is the same as SHTWEIB2, no input or output screens are illustrated here. If the program will not run because of an out of memory error, go back and reduce the number of engines in the analysis. Also remember that the number of failure modes should not exceed one in order to maximize the number of engines that can be run.

12. WEIBAYES is a code that is used when there is insufficient failure data to calculate critical life for a failure mode that is known to exist. Typically the failure mode will give some idea as to the Weibull slope Beta, either from past history or from code nine - BETAHIST. It is for this reason that it is important to record all values of Beta and their corresponding failure modes. The WEIBAYES input screen, not shown, asks if the value of the characteristic life Eta is known. If Eta is not known the user will be directed to go to the ETACALC code (code six) to calculate a best estimate of Eta. Strictly speaking code number six is the WEIBAYES calculation of the value of 'ETA'. The WEIBAYES code uses that value of 'ETA' to calculate a user designated value of critical life. If Eta is known, or upon returning from code six, input data will

be requested next in the form of data statements as shown in figure 34. The first input requested is the B.1 life (or other value (such as B.001, B10, etc.) or percent of the population allowed to fail. If the part being investigated is a critical part, such as a disk, then the input should be a very low B-life. Any number can be input up to 0.999999, which is equivalent to 99.9999%. If the desired life was the B10 life then the input would be:

4000 DATA 0.10

The next input is the assumed value of Beta and the calculated Eta. This input would appear as:

4040 DATA 3,1000

if Beta were three and Eta were 1000.

The code now calculates the percent allowed to fail and the equivalent number of hours to arrive at that percent failures. The output screen is shown in Figure 35 and contains a short explanation of the answer. It also gives the user an opportunity to make another calculation if the answer is unsuitable. This code is especially useful for critical life parts where even one failure can be considered catastrophic. Requirements can be determined for parts life improvement to achieve a desired specific life in terms of an allowed failure percentages.

13. ZOFALSB is a code that provides the definition of a test plan that will demonstrate that a redesigned part has either eliminated or substantially improved a known failure mode. The resulting plan, when passed, represents substantiation that an engineering change or fix has solved the problem presented by the failure mode. This particular test plan generation is for those cases where there will be some fixed number of test units, each tested for a certain number of hours or cycles, without any failures. If there is a failure prior to each test unit completing the required number of hours, the test is failed. Zero failures means the statistical requirement has been met for substantiation of the fix.

The inputs for this code are: (1) the Weibull slope Beta, (2) the characteristic life Eta, and (3) an assumed number of test hours that each test article must successfully complete. The input screen is shown as figure 36. The code first calculates the ratio of the test hours to the characteristic life and then presents a table on the screen from which the number of required test articles can be determined. See figures 37 and 38. The upper limit of test articles has been chosen as fifty and the lower limit is a statistical limit of three. Since the table can still indicate the requirement to test a very large and

 UNREASONABLE SAMPLE (OR A SAMPLE SIZE OF OVER FIFTY, INDICATED BY  
 \*\*) YOU SHOULD NOW MAKE ANOTHER ESTIMATE OF TEST HOURS OR OPT FOR  
 ANOTHER METHOD OF TEST PLAN DETERMINATION.

PLEASE CHOOSE FROM THE FOLLOWING OPTIONS:

1. DISPLAY THE TEST PLAN FOR CURRENT SAMPLE SIZE OF 6
2. MAKE ANOTHER ESTIMATE OF TEST HOURS.
3. USE ALTERNATE TEST PLAN METHOD.

INPUT OPTION NUMBER FROM THE ABOVE LIST?

FIGURE 39              ZOFILSB OUTPUT SCREEN 1

THE TEST PLAN CONSISTS OF THE FOLLOWING:

SAMPLE SIZE IS 6

TEST HOURS ARE 1500

IF ALL THE SAMPLES SURVIVE THE TEST WITHOUT FAILURE THEN THE FAILURE MODE WHERE

BETA = 2.5 AND ETA = 2000

HAS BEEN EITHER ELIMINATED OR SIGNIFICANTLY IMPROVED.  
THE TEST TIME IS 75 PERCENT OF THE CHARACTERISTIC LIFE OF 2000 HOURS.

FIGURE 40 ZOFILSB OUTPUT SCREEN 2

THE ALTERNATE TEST PLAN METHOD REQUIRES THE INPUT OF A REASONABLE NUMBER OF UNITS FOR TEST (SAMPLE SIZE) AND THE SELECTION OF A TEST HOUR RATIO FROM THE FOLLOWING TABLE. MAKE AN ESTIMATE OF A REASONABLE SAMPLE SIZE? 4

NOW CHOOSE THE NEAREST VALUE OF THE WEIBULL SLOPE BETA AND THE SAMPLE SIZE YOU JUST ESTIMATED AND THEN NOTE THE CORRESPONDING TEST HOUR RATIO.

PRESS ENTER TO CONTINUE?

FIGURE 41 ZOFILSB ALTERNATE PLAN INPUT SCREEN

inappropriate number of test articles, the code next gives the opportunity to revise the test hours in order to adjust the number of required test articles (figures 39 and 40). This adjustment is usually upward since that results in fewer test articles. After one or more adjustments to the test hours it may be apparent that the solution is still not converging to an acceptable number of test articles. In this case there is the choice available to use an alternate test plan method. See option 3 on figure 39.

Using the alternate test plan method requires the initial selection of a reasonable number of test articles as well as Beta and Eta (see figure 41). The code then presents another table (figure 42) which allows a resulting number of test hours to be determined. Again, the opportunity is presented to make another choice if the test plan still is not optimum. This procedure can be repeated as many times as required in order to arrive at the optimum zero-failure test plan. It should be noted that an optimum zero-failure test plan almost always results in fewer total test hours than plans generated to allow for one or more failures. Optimum in this case would be for a minimum of total test time.

14. NZFTSTP is a code that provides substantiation that a fix has either eliminated a failure mode or significantly improved it. In this case one or more failures are allowed, hence it is a non-zero-failure test plan. The introductory screen is shown in figure 43. Inputs are shown in figure 44. The first input is the probability of passing the test, demonstrating a significantly improved failure characteristic, if no fix is introduced. This obviously is a small probability such as ten percent, or 0.1. Next is input the probability of passing the test if a good fix is introduced. This should be a much higher probability such as ninety percent, or 0.9. The next inputs are the characteristic life Eta before the fix and the desired characteristic life with the fix. The increase in Eta should indicate a significant decrease in the probability of an early failure. Next, a reasonable number of test hours is input which represents the target test time that each test article is to be tested to. The last input is the Weibull slope Beta for the failure mode in question.

The code now runs in an iterative mode which halts at certain points that show agreement between the assumed probabilities of passing the tests and the calculated values. The screen displays these interim results and as the calculation stops, the user is asked to press the F5 (Function 5) key to continue the iteration. Figures 45 and 46 show samples of the iterative screens. When the last iteration is complete the code automatically shows a table of results (figure 47). The user is asked to select values from this table, (N0, N1, and R0) and input them at the prompts. The final calculation is then made to result in the final test plan. The results are presented on the screen (See figure 48) in terms of a sample size, each of which must be tested for some reasonable amount of time that was input earlier. The allowed number of failures, which must not be exceeded, is also given. Also presented is the total number of test hours that would be run assuming there were no test failures. This represents the maximum test

| SAMPLE<br>SIZE | BETA |      |      |      |      |      |      |      |      |      |

THE SAMPLE SIZE, EACH OF WHICH MUST BE TESTED FOR 1000 HOURS, IS:

$$\text{SAMPLE SIZE} = 33$$

IF 2 OR LESS FAILURES OCCUR THE TEST IS PASSED.

MAXIMUM TOTAL TEST HOURS IF ALL TEST UNITS RUN W/O FAILURE =  
33000 HOURS

FIGURE 48 NZFTESTP OUTPUT SCREEN 2

hours that would be run for a 100% successful test. This number can be used as an indication of whether the test is too long. Also, the number of test articles may be too large and require that a new test plan be formulated with a higher number of test hours per test article. Whatever the result, the user is given the opportunity to do another analysis or quit and return to the menu.

## SAMPLE SOLUTIONS

This section contains sample solutions for each of the codes addressed in this report, including WEIBER, which shows the menu and the Help screens. The sample solutions are meant to be illustrative only and are not meant to represent any specific engine or actual engine or parts problem. It is hoped that between the sample solutions, the previous explanations, and the code listing of Appendix A, readers with a desire to utilize the codes will be successful without spending a great deal of time in the learning process. As the codes mature with further use and modification, they will become more useful and be applicable to a broader range of gas turbine engine problems. A more comprehensive user's manual may also be written in the near future if it is required.

\*\*\* HELP FOR WEIBULL ANALYSIS ROUTINE \*\*\*

THIS IS A SYSTEMATIC ROUTINE FOR MAKING FAILURE ANALYSES BASED ON THE WEIBULL DISTRIBUTION METHODOLOGY. THE SERIES OF CODES THAT MAKE UP THE ROUTINE ARE WRITTEN FOR GAS TURBINE ENGINE PART FAILURES BUT CAN BE APPLIED TO ANY TYPE EQUIPMENT THAT CORRELATES IN A WEIBULL DISTRIBUTION.

THE FOLLOWING IS A LIST OF THE AVAILABLE CODES AND THEIR FUNCTIONS. YOU MAY USE ANY CODE AS A STAND-ALONE ANALYTICAL TOOL.

PRESS ANY KEY TO CONTINUE.?

1. WEIBULL PARAMETER CALCULATION (SUSWEIBL) - THIS CODE IS USED TO CALCULATE THE WEIBULL SLOPE 'BETA' AND THE CHARACTERISTIC LIFE 'ETA' USING A SAMPLE COMPOSED OF BOTH FAILURES AND SUSPENDED UNITS. SUSPENDED UNITS ARE THOSE THAT ARE NON-FAILED OR NOT FAILED BY THE MODE UNDER CONSIDERATION. DATA REQUIRED ARE: (1) NUMBER OF UNITS IN THE SAMPLE, (2) NUMBER OF FAILED UNITS IN THE SAMPLE, AND (3) NUMBER AND AGE OF EACH UNIT OR GROUP OF UNITS WITH THE SAME AGE. THE OUTPUT FROM THIS CODE IS: (1) BETA, (2) ETA, (3) B-10 LIFE, (4) B-50 LIFE, (5) LEAST SQUARES CORRELATION COEFFICIENT, AND (6) THE INSTANTANEOUS FAILURE RATE VERSUS THE AGE OF THE UNITS. IF BETA IS KNOWN, OR IF YOU HAVE A GOOD ESTIMATE OF BETA, YOU MAY USE OPTION 6, 'CHARACTERISTIC LIFE CALCULATION.'

PRESS THE ENTER KEY TO CONTINUE.?

2. PRESENT RISK ANALYSIS (PRESRISK) - THIS CODE IS USED TO CALCULATE THE EXPECTED NUMBER OF FAILURES TO HAVE OCCURRED TO DATE OVER THE LIFE OF THE UNITS OF THE SAMPLE. THE CODE IS EXCELLENT FOR VERIFYING THE FAILURES AS WELL AS 'ETA' BY COMPARING ANSWERS WITH KNOWN FAILURES IN THE POPULATION. DATA REQUIRED ARE: (1) BETA, (2) ETA, (3) NUMBER AND AGE OF EACH UNIT OR GROUP OF UNITS WITH THE SAME AGE. THE OUTPUT FROM THE CODE IS: (1) THE PERCENT IN EACH GROUP EXPECTED TO FAIL, (2) THE NUMBER IN EACH GROUP EXPECTED TO FAIL, AND (3) THE TOTAL NUMBER OF EXPECTED FAILURES FOR THE POPULATION.

PRESS THE ENTER KEY TO CONTINUE.?

3. FUTURE RISK ANALYSIS (FUTRISKS) - THIS CODE IS USED TO CALCULATE THE EXPECTED NUMBER OF FAILURES OVER A SPECIFIED FUTURE TIME PERIOD FOR A POPULATION THAT ACCUMULATES MORE OPERATING TIME OVER THAT TIME PERIOD. IT IS ASSUMED THAT THERE ARE NO REPAIRS SO FAILURES ARE FOR THE ORIGINAL POPULATION ONLY. FOR A MORE COMPLEX ANALYSIS WHERE PARTS ARE REPAIRED AND RETURNED TO SERVICE, SEE OPTION 4, THE MONTE CARLO RISK ANALYSIS. DATA REQUIRED ARE: (1) BETA, (2) ETA, (3) MONTHS INTO THE FUTURE THAT THE ANALYSIS WILL COVER, (4) AVERAGE MONTHLY OPERATING HOURS PER UNIT OVER THE TIME PERIOD, AND (5) NUMBER AND AGE OF EACH GROUP OF UNITS WITH THE SAME AGE. THE OUTPUT FROM THIS CODE IS: (1) THE PERCENT IN EACH GROUP EXPECTED TO FAIL, (2) THE NUMBER IN EACH GROUP EXPECTED TO FAIL, (3) CUMULATIVE FAILURES, AND (4) THE TOTAL NUMBER OF EXPECTED FAILURES IN THE POPULATION.

PRESS THE ENTER KEY TO CONTINUE.?

4. WEIBULL FAILURE ANALYSIS - MONTE CARLO (WEIBRISK) - THIS CODE IS A COMPREHENSIVE ANALYTICAL TOOL THAT CAN BE USED TO FORECAST NUMBERS OF FAILURES AS WELL AS THE FAILURE TIMES IN TERMS OF OPERATING HOURS OR CYCLES. IT IS A STATISTICAL CODE THAT MAKES THOUSANDS OF CALCULATIONS TO ALLOW STATISTICAL AVERAGES TO BE CALCULATED. IT IS EXTREMELY ACCURATE WHEN REQUIRED INPUT DATA IS EXTREMELY ACCURATE. IT IS CAPABLE OF PROVIDING SENSITIVITIES SO THAT LESS ACCURATE DATA CAN BE USED TO ARRIVE AT REASONABLE SOLUTIONS AND ALLOW FOR IMPACT ANALYSIS. DATA REQUIRED ARE: (1) BETA, (2) ETA, (3) NUMBER AND AGE OF EACH GROUP OF UNITS WITH THE SAME INITIAL TIME, (4) TOTAL NUMBER OF ENGINES IN THE SAMPLE, (5) NUMBER OF MONTHS IN THE ANALYSIS, (6) AVERAGE OPERATING HOURS PER MONTH PER PART OVER THE TIME OF THE ANALYSIS, (7) THE INSPECTION INTERVAL AT WHICH, IF REACHED BEFORE A FAILURE OCCURS, ALL PARTS CONSIDERED ARE MADE GOOD-AS-NEW OR ZERO-TIMED, (8) NUMBER OF FAILURE MODES IN THE ANALYSIS, AND (9) THE ENGINE NAME. NOTE THAT BETA AND ETA MUST BE FURNISHED FOR EACH FAILURE MODE. ALSO NOTE THAT LARGE NUMBERS OF ENGINES AND MULTIPLE FAILURE MODES GREATLY INCREASE THE RUN TIME.

5. WEIBULL FAILURE ANALYSIS - SHORT PRINT-OUT (SMRTWEIB) - THIS CODE IS ALMOST IDENTICAL TO THE PREVIOUS CODE EXCEPT FOR THE AMOUNT OF OUTPUT. IN ORDER TO SPEED UP THE ANALYSIS, ONLY NUMBERS OF FAILURES ARE OUTPUT AND FAILURE TIMES AND MODES OF FAILURE ARE ELIMINATED. THIS CODE IS VERY USEFUL AFTER IT HAS BEEN DETERMINED WHICH FAILURE MODES DOMINATE AND SHEER NUMBERS ARE OF PRIME INTEREST. MANY MORE ENGINES MAY BE ANALYSED IN THE SAME AMOUNT OF TIME AND THE VOLUME OF PAPER GENERATED IS VERY SIGNIFICANTLY LESS.

PRESS THE ENTER KEY TO CONTINUE.?

4. WEIBULL FAILURE ANALYSIS - MONTE CARLO (WEIBRISK) - THIS CODE IS A COMPREHENSIVE ANALYTICAL TOOL THAT CAN BE USED TO FORECAST NUMBERS OF FAILURES AS WELL AS THE FAILURE TIMES IN TERMS OF OPERATING HOURS OR CYCLES. IT IS A STATISTICAL CODE THAT MAKES THOUSANDS OF CALCULATIONS TO ALLOW STATISTICAL AVERAGES TO BE CALCULATED. IT IS EXTREMELY ACCURATE WHEN REQUIRED INPUT DATA IS EXTREMELY ACCURATE. IT IS CAPABLE OF PROVIDING SENSITIVITIES SO THAT LESS ACCURATE DATA CAN BE USED TO ARRIVE AT REASONABLE SOLUTIONS AND ALLOW FOR IMPACT ANALYSIS. DATA REQUIRED ARE: (1) BETA, (2) ETA, (3) NUMBER AND AGE OF EACH GROUP OF UNITS WITH THE SAME INITIAL TIME, (4) TOTAL NUMBER OF ENGINES IN THE SAMPLE, (5) NUMBER OF MONTHS IN THE ANALYSIS, (6) AVERAGE OPERATING HOURS PER MONTH PER PART OVER THE TIME OF THE ANALYSIS, (7) THE INSPECTION INTERVAL AT WHICH, IF REACHED BEFORE A FAILURE OCCURS, ALL PARTS CONSIDERED ARE MADE GOOD-AS-NEW OR ZERO-TIMED, (8) NUMBER OF FAILURE MODES IN THE ANALYSIS, AND (9) THE ENGINE NAME. NOTE THAT BETA AND ETA MUST BE FURNISHED FOR EACH FAILURE MODE. ALSO NOTE THAT LARGE NUMBERS OF ENGINES AND MULTIPLE FAILURE MODES GREATLY INCREASE THE RUNNING TIME. THE OUTPUT FROM THIS CODE IS: (1) FAILURE TIMES (2) NEW FAILURE TIMES, (3) NUMBER OF FAILURES PER ENGINE, (4) IDENTIFICATION OF FAILURE MODE, (5) AVERAGE NUMBER OF FAILURES PER ENGINE OVER THE NUMBER OF ITERATIONS, (6) CUMULATIVE FAILURES PER ENGINE, AND (7) AVERAGE FAILURES FOR ALL ENGINES FOR ALL ITERATIONS.

PRESS ENTER KEY TO CONTINUE.?

5. WEIBULL FAILURE ANALYSIS - SHORT PRINT-OUT (SHRTWEIB) - THIS CODE IS ALMOST IDENTICAL TO THE PREVIOUS CODE EXCEPT FOR THE AMOUNT OF OUTPUT. IN ORDER TO SPEED UP THE ANALYSIS, ONLY NUMBERS OF FAILURES ARE OUTPUT AND FAILURE TIMES AND MODES OF FAILURE ARE ELIMINATED. THIS CODE IS VERY USEFUL AFTER IT HAS BEEN DETERMINED WHICH FAILURE MODES DOMINATE AND SHEER NUMBERS ARE OF PRIME INTEREST. MANY MORE ENGINES MAY BE ANALYSED IN THE SAME AMOUNT OF TIME AND THE VOLUME OF PAPER GENERATED IS VERY SIGNIFICANTLY LESS.

PRESS THE ENTER KEY TO CONTINUE.?

6. CHARACTERISTIC LIFE CALCULATION (ETACALC) - THIS CODE IS USEFUL WHEN BETA IS KNOWN FOR THE FAILURE MODE AND GOOD FAILURE DATA IS AVAILABLE TO CALCULATE ONLY THE CHARACTERISTIC LIFE. DATA REQUIRED ARE: (1) BETA, (2) TOTAL NUMBER OF FAILURES THAT DATA IS AVAILABLE FOR, AND (3) DATA PAIRS OF NUMBERS OF FAILURES AND OPERATING TIME AT FAILURE. THE OUTPUT FROM THIS CODE IS THE CALCULATED VALUE OF THE CHARACTERISTIC LIFE.

PRESS THE ENTER KEY TO CONTINUE.?

7. CONFIDENCE INTERVAL CALCULATION (CNFINTBE) - THIS CODE CALCULATES UPPER AND LOWER CONFIDENCE BOUNDS FOR BOTH BETA AND TIME TO FIRST FAILURE. CALCULATIONS CAN BE MADE FOR CONFIDENCE LEVELS OF 0.90, 0.95, OR 0.99. THESE UPPER & LOWER LIMITS ARE INDICATIONS OF THE ACCURACY ONE CAN EXPECT FROM THE MANY CALCULATIONS THAT CAN BE MADE FROM THESE CODES.

PRESS THE ENTER KEY TO CONTINUE.?

8. RELIABILITY AND CONFIDENCE INTERVALS FOR RELIABILITY (RELIARTY) - THIS CODE CALCULATES THE RELIABILITY OF A COMPONENT AT ANY TIME BASED ON THE VALUES OF BETA AND ETA. YOU MAY THEN CALCULATE THE CONFIDENCE INTERVAL FOR THIS RELIABILITY AT A CONFIDENCE LEVEL OF 0.90, 0.95, OR 0.99. ALSO PRESENTED IS THE CORRESPONDING PROBABILITY OF FAILURE.

PRESS THE ENTER KEY TO CONTINUE.?

9. HISTORICAL BETA VALUES (BETAHIST) - THIS CODE PRINTS OUT A LIST OF PROBABLE VALUES OR RANGES OF BETA FOR SOME COMMON MODES OF FAILURE IN GAS TURBINE COMPONENTS. WHILE THESE HISTORICAL VALUES SHOULD NOT BE TAKEN AS ABSOLUTE, THEY REPRESENT REASONABLE STARTING VALUES, ESPECIALLY FOR PERFORMING SENSITIVITY ANALYSES.

PRESS THE ENTER KEY TO CONTINUE.?

10. WEIBULL PARAMETER CALCULATION (PWA CO) - THIS CODE IS SIMILAR TO CODE NUMBER 1 EXCEPT THAT IT CAN PROVIDE THE VALUES OF BETA AND ETA WHICH MAXIMIZE THE 'LIKELIHOOD' OF OBTAINING THE OBSERVED DATA. THERE ARE CASES WHERE THESE VALUES MAY BE DIFFERENT THAN THOSE OBTAINED IN CODE 1 BY A REASONABLE AMOUNT. IF THERE IS A QUESTION, BOTH CODES SHOULD BE RUN AND SENSITIVITIES ESTABLISHED.

PRESS THE ENTER KEY TO CONTINUE.?

11. WEIBULL FAILURE ANALYSIS FOR OVER 1100 ENGINES/PARTS -  
THIS CODE IS SIMILAR TO THE PREVIOUS TWO MONTE CARLO CODES EXCEPT THAT IT IS OPTIMIZED TO ANALYZE A MAXIMUM OF ENGINES/PARTS. THIS CODE SHOULD BE USED AFTER THE DOMINANT FAILURE MODE HAS BEEN DETERMINED AND NO MORE THAN ONE FAILURE MODE SHOULD BE ANALYZED AT A TIME. THE INPUT IS THE SAME AS IN CODES (4) AND (5) BUT THE OUTPUT IS LIMITED TO THAT OF CODE (5). ONLY THE TOTAL FAILURES ARE GIVEN PER ITERATION ALONG WITH THE AVERAGES.

PRESS THE ENTER KEY TO CONTINUE.?

12. WEIBAYES, WHEN WEIBULL PLOTS ARE NOT POSSIBLE -  
WHEN THERE IS INSUFFICIENT FAILURE DATA TO CALCULATE THE WEIBULL SLOPE BETA AND THE CHARACTERISTIC LIFE ETA WE MAY MAKE ASSUMPTIONS TO ARRIVE AT THE BEST ESTIMATES AND MAKE CALCULATIONS TO DETERMINE THE DESIRED LIFE, I.E., B.1, B1, B10, OR B50 LIFE. FIRST, IT IS NECESSARY TO MAKE THE BEST GUESS REGARDING THE FAILURE MODE SUCH AS LCF, HCF, OR OTHERS. THEN USE CODE (6), CHARACTERISTIC LIFE CALCULATION, TO DETERMINE A BEST ESTIMATE OF ETA. THESE FORM THE INPUT FOR THIS CODE WHICH THEN CALCULATES THE APPROPRIATE LIFE OF THE PART IN QUESTION.

PRESS THE ENTER KEY TO CONTINUE.?

13. ZERO-FAILURE TEST PLAN FOR SUBSTITUTION TESTING -  
THIS CODE CALCULATES THE NUMBER OF ENGINES/PARTS THAT MUST BE TESTED WITHOUT FAILURE IN ORDER TO DEMONSTRATE THAT A GIVEN FAILURE MODE HAS BEEN EITHER ELIMINATED OR SUBSTANTIALLY IMPROVED. INPUTS REQUIRED ARE (1) WEIBULL SLOPE BETA, (2) CHARACTERISTIC LIFE ETA, AND (3) AN ESTIMATE OF A REASONABLE AMOUNT OF TEST TIME, RECOGNIZING THAT AT LEAST THREE PARTS OR MORE MUST EACH BE TESTED FOR THAT AMOUNT OF TIME. THE CODE ALLOWS A SECOND AND THIRD TEST TIME ESTIMATE (OR MORE) AND ALSO PROVIDES FOR AN ALTERNATE METHOD OF TEST PLAN FORMULATION. THEN TEST PLAN IS OUTPUT IN TERMS OF A SAMPLE SIZE, EACH OF WHICH MUST BE TESTED FOR A GIVEN NUMBER OF HOURS WITHOUT FAILURE IN ORDER TO DEMONSTRATE A SIGNIFICANT IMPROVEMENT IN LIFE.

WEIBAYES ANALYSIS  
WHEN WEIBULL PLOTS ARE IMPOSSIBLE  
DUE TO A LACK OF FAILURE DATA  
WRITTEN BY JAMES L. BYERS  
NAVAL AIR DEVELOPMENT CENTER, CODE 6052  
HARMINSTER, PA 18974

LIFE CALCULATION FOR WEIBAYES

PERCENT OF POPULATION ALLOWED TO FAIL = 10 (CALCULATED VALUE).

THE CALCULATED LIFE USING THE INPUT VALUE OF BX IS EQUAL TO 472.3088

IF THIS VALUE IS SMALLER THAN ACCEPTABLE THEN THE CALCULATED VALUE OF ETA (CHARACTERISTIC LIFE) IS TOO SMALL. THIS MAY BE DUE TO A LACK OF SUFFICIENT OPERATING TIME USED IN THE CALCULATION OF ETA. INSUFFICIENT DATA INDICATES A NEED TO EXERCISE CONSERVATISM UNTIL ENOUGH OPERATIONAL EXPERIENCE IS OBTAINED WITHOUT A FAILURE (OR FEW FAILURES) SUCH THAT A HIGHER VALUE OF ETA IS CALCULATED.

BETA USED WAS 3      ETA USED WAS 1000 .

WEIBAYES ANALYSIS  
WHEN WEIBULL PLOTS ARE IMPOSSIBLE  
DUE TO A LACK OF FAILURE DATA  
WRITTEN BY JAMES L. BYERS  
NAVAL AIR DEVELOPMENT CENTER, CODE 6052  
WARMINSTER, PA 18974

DATA INPUT ----- ENTER THE FOLLOWING:

4000 DATA B1

WHERE B1 = THE PERCENT OF THE POPULATION ALLOWED  
TO FAIL, i.e., 0.001 FOR B.1 LIFE  
DO NOT USE 1.0 OR ANY PERCENT > 0.999999

4040 DATA B,H

WHERE B = THE ASSUMED VALUE OF THE WEIBULL SLOPE  
'BETA' AND H = THE CALCULATED VALUE OF THE CHARACTERISTIC  
LIFE 'ETA'

WHEN ALL DATA IS ENTERED, INPUT (RUN 1040) TO CONTINUE.

Break in 1046

OK

4000 DATA 0.10

4040 DATA 3,1000

LIFE CALCULATION FOR WEIBAYES

PERCENT OF POPULATION ALLOWED TO FAIL = 10 (CALCULATED VALUE).

THE CALCULATED LIFE USING THE INPUT VALUE OF B1 IS EQUAL TO 472.3088

IF THIS VALUE IS SMALLER THAN ACCEPTABLE THEN THE CALCULATED VALUE OF  
ETA (CHARACTERISTIC LIFE) IS TOO SMALL. THIS MAY BE DUE TO A LACK OF  
SUFFICIENT OPERATING TIME USED IN THE CALCULATION OF ETA. INSUFFICIENT  
DATA INDICATES A NEED TO EXERCISE CONSERVATISM UNTIL ENOUGH OPERATIONAL  
EXPERIENCE IS OBTAINED WITHOUT A FAILURE (OR FEW FAILURES) SUCH THAT A  
HIGHER VALUE OF ETA IS CALCULATED.

BETA USED WAS 3      ETA USED WAS 1000 .

ZERO FAILURE TEST PLAN GENERATION  
NUMBER OF TEST UNITS AND TEST TIME FOR EACH  
WRITTEN BY  
WRITTEN BY: JAMES L. BYERS, CODE 6052  
NAVAL AIR DEVELOPMENT CENTER  
WARMINSTER, PA 18974

VERSION 17 MAY 87

THE TEST PLAN CONSISTS OF THE FOLLOWING:

SAMPLE SIZE IS 19

TEST HOURS ARE 1000

IF ALL THE SAMPLES SURVIVE THE TEST WITHOUT FAILURE THEN THE FAILURE MODE WERE

$BETA = 3$  AND  $ETA = 2000$

HAS BEEN EITHER ELIMINATED OR SIGNIFICANTLY IMPROVED.  
THE TEST TIME IS 50 PERCENT OF THE CHARACTERISTIC LIFE OF 2000 HOURS.

SECOND ESTIMATE OF TEST HOURS

THE TEST PLAN CONSISTS OF THE FOLLOWING:

SAMPLE SIZE IS 4

TEST HOURS ARE 1000

IF ALL THE SAMPLES SURVIVE THE TEST WITHOUT FAILURE THEN THE FAILURE MODE WERE

$BETA = 3$  AND  $ETA = 2000$

HAS BEEN EITHER ELIMINATED OR SIGNIFICANTLY IMPROVED.  
THE TEST TIME IS 90 PERCENT OF THE CHARACTERISTIC LIFE OF 2000 HOURS.

ALTERNATE TEST PLAN METHOD

THE ALTERNATE TEST PLAN METHOD REQUIRES THE INPUT OF A REASONABLE NUMBER OF UNITS FOR TEST (SAMPLE SIZE) AND THE SELECTION OF A TEST HOUR RATIO FROM THE FOLLOWING TABLE. MAKE AN ESTIMATE OF A REASONABLE SAMPLE SIZE? 1800

NOW CHOOSE THE NEAREST VALUE OF THE WEIBULL SLOPE BETA AND THE SAMPLE SIZE YOU JUST ESTIMATED AND THEN NOTE THE CORRESPONDING TEST HOUR RATIO.

PRESS ENTER TO CONTINUE?

THE TEST PLAN NOW CONSISTS OF THE FOLLOWING:

SAMPLE SIZE IS 1800

TEST HOURS ARE 1832

IF ALL THE SAMPLES SURVIVE THE TEST WITHOUT FAILURE THEN THE FAILURE MODE WHERE

BETA = 3 AND ETA = 2000  
HAS BEEN EITHER ELIMINATED OR SIGNIFICANTLY IMPROVED.  
THE TEST TIME IS 91.6 PERCENT OF THE CHARACTERISTIC LIFE OF 2000 HOURS.

## HISTORICAL BETA VALUES

While there are no guaranteed values of Weibull parameters that can be used in any Weibull analysis, there are values of the Weibull slope Beta that seem to occur frequently as nearly constant values for certain classes of failures. In some cases these will be given as a range of values to more accurately reflect how they occur. Even if these values cannot be counted on to be exact, they can be used as a starting point, especially when there is very little data available to calculate Beta with the SUSWEIBL code. If one performs a lot of Weibull analyses, all values of Beta that are validated should be retained in a library for future reference. In addition, as more failure data becomes available for any specific analysis, the analysis should be updated to include the new data. This is especially true of the calculation of Beta and the characteristic life Eta.

The following is a list of Beta values that have been obtained from the references and actual problems:

| <u>FAILURE MODE</u>                              | <u>BETA VALUE</u> |
|--------------------------------------------------|-------------------|
| 1. Bearings, general failures.....               | 1.5               |
| 2. Crack, flange.....                            | 9.5               |
| 3. Erosion, turbine vane.....                    | 3.0               |
| 4. LCF, compressor case.....                     | 5.0               |
| 5. LCF, compressor disk.....                     | 3.0               |
| 6. LCF, nozzle bearing.....                      | 1.5               |
| 7. LCF, general.....                             | 2.0-->5.0         |
| 8. Performance deterioration.....                | 4.0-->5.0         |
| 9. Rotating structure.....                       | 6.0-->8.0         |
| 10. Static structure.....                        | 4.0-->6.0         |
| 11. Thermal LCF, combustor.....                  | 3.0               |
| 12. The following cases all have the same value: |                   |
| Independence of time                             |                   |
| Ingestion (FOD) & misuse                         |                   |
| Insufficient redundancy                          |                   |
| Maintenance errors                               |                   |
| Mixtures of problems                             |                   |
| Original design deficiencies                     |                   |
| Random failures.....                             | 1.0               |

The value of the Weibull slope also has the following meanings or indications:

\* Slopes less than 1.0 are infant mortality where the reliability will increase with age. It also indicates a quality problem such as misassembly (slope usually about 0.5).

- \* Slopes that are greater than 1.0 are generally wearout for one reason or another.
- \* A slope of approximately 2.5 is usually gradual wearout.
- \* A slope of 3.44 approximates the bell-shaped curve of a Normal distribution.
- \* Slopes that are greater than about 4.5 are usually rapid wearout (brick wall).
