Introduction

This document reports on the efforts of the MRC/UW/LLNL team to define the IRAS confused regions. We undertake to improve point source counts in a subset of the regions we define. The subset will be limited only by the availability of survey data in the regions which are identified as point source confused by the current (Ver 2.0) IRAS point source catalog (PSC). Available coincident AO data will be an important validation source.

The sensitivity and spatial resolution capabilities of the IRAS telescope failed to resolve individual sources in many regions of high source density. Approximately 10% of the sources catalogued in the PSC are tagged as 'confused' in some way; the location of a source, the number of sources at a location, the temporal occurrence and variation of a source, and/or the intensity of a source(s) was not discernible by the source identification/discrimination methods used to compile the PSC. In these regions of infrared clutter, the PSC can underestimate the number of point sources by as much as a factor of 3 to 5 in the IRAS Bands 1 and 2 (12 and 25 microns respectively).

Our analysis for improved source counts is designed to enhance the description and spatial definition of the mid- and long wavelength infrared celestial background, and includes generation of high spatial resolution images of the confused regions. Analysis of these images will improve the accuracy of source counts, locations, and flux estimates in the PSC. More detailed knowledge of the high source density regions will improve our ability to understand star formation and galactic evolution. It will also greatly improve our knowledge of a type of celestial background which presents a serious clutter problem for space-born surveillance system sensors. *Tables Data. (JND)*

The IRAS Explanatory Supplement (ES) reports that the major areas affected by confusion in the 12 and 25 micron bands are mainly in the galactic plane, plus small regions in Orion, Cygnus, Ophiuchus, and the Magellanic clouds. The 'galactic plane region' is a band six to ten degrees wide centered on the galactic plane with 100 degrees of extent in galactic longitude on both sides of the center. Figures 1 and 2 show all-sky maps of these high source density regions for 12 and 25 microns, respectively as presented in the IRAS ES. Figure 3 is a montage of NASA-produced galactic plane sky flux plates for the galactic center region

(extent in galactic longitude is ± 37 degrees) at 12 microns. The three extracted sub-regions at the bottom of the figure are the initial areas of interest for MRC/UW/LLNL high-res re-imaging. The sub-regions are centered at $l = 30, 0,$ and 330 degrees, respectively. Each plate is approximately 16 square degrees.

Generation of Confusion Maps

MRC has generated a set of image maps identifying the IRAS point source confusion regions. Sources which appear in the maps have the confuse flag set in their PSC catalog entries. A set confuse flag results from repeated indications of a near neighbor(s) during catalog processing, and means that something other than an isolated source exists at the location in question.

During the last 2 months, we have developed utility FORTRAN software to identify, extract, and graphically display confused regions of interest selected from the tape release version of PSC (containing 245,889 source entries) using the point source confusion flags. For the purposes of our analysis, the binary image data files are displayed on a SUN SPARC(tm) workstation, using IDL(tm) (Research Systems, Inc.) in galactic coordinates, where the galactic latitude and longitude ($[l,b]$) position of a tagged "confused" source (calculated from the IRAS equatorial PSC coordinates) is used to map a given source to the appropriate image array pixel position ($[x,y]$), while the luminance value assigned to that pixel is mapped using various confusion flags.

The size of the output binary image, the region of interest in an $[l]$ and $[b]$ window, the IRAS band selection criteria, the point source limiting magnitude, and pixel luminance value mapping are all user defined variables, supplied to the main FORTRAN source code by a parameter file. The user also may specify whether to create: 1) a dump file containing the source name, position (both equatorial and galactic coordinates), and confusion flags; and/or 2) a source attributes files containing detailed information (e.g. stellar spectral type, astronomical catalog cross-identifications, etc.) about each extracted object. The source code is constructed to execute either in batch or interactive modes, with typical execution times of approximately 460 to 1300 sec on a SUN SPARC. The ability to identify confused regions at 12 and 25 microns from the PSC with this utility code will

guide the selection and acquisition of the proper AOs and survey data HCONs for the Hi-Res PSC Addenda initiative.

The most common usage of this utility software is to generate full sky scenes of IRAS band selected confused regions, with image luminance proportional to source confusion. The confusion flags listed in the PSC include an estimate of the number of neighboring sources around a given source that were found in either the point or small extended source Working Survey Data Base (WSDB), and a flag which was set during the seconds-confirmed, hours-confirmed, and/or band-merging process (ES, V.D and VII.H), designated the "confuse flag." As a primary discriminator of point source confused regions, we have utilized the confuse flag, which is related to the repeated occurrence of near neighbor confusion during the processing of a source.

The confuse flag (CFLAG) is hex-encoded by band, one bit per band (e.g. [12,25,60,100]), and may have any combination of values from [0000] = 0 hex (the confuse flag not set in any band), to [1111] = 15 hex, (the confuse flag set in all bands). Regions of high source density are well correlated with the distribution of sources in the PSC that have the confuse flag set. To further delineate the extent of confusion associated with a given source culled from the PSC, we can augment the confuse flag data bit with one additional band encoded flag, the small extended source neighbor counts (SES1, SES2), and two global flags, the point source neighbor flag (PNEARH, PNEARW), and a cirrus flag (CIRR1, CIRR2). Using the above data flags, luminance values (i_{pixbit}) can be assigned to the appropriate image pixel based on the following criteria:

- 1) $i_{\text{pixbit}} = \text{CFLAG} * (\text{SES1}[k] * \text{SES2}[k]) + \text{PNEARH} + \text{PNEARW}$
- 2) $i_{\text{pixbit}} = \text{PNEARH} + \text{PNEARW}$
- 3) $i_{\text{pixbit}} = \text{CIRR1} + \text{CIRR2}$
- 4) $i_{\text{pixbit}} = \text{CFLAG}$
- 5) $i_{\text{pixbit}} = \text{CFLAG} * ((\text{SES1}[k]) * (\text{SES2}[k]))$
- 6) $i_{\text{pixbit}} = \text{SES1}[k] * \text{SES2}[k]$

where $[k]$ can have a value of 1 to 4 (i.e., IRAS Band 1 though 4). In confusion scenes generated by extracting more than a single IRAS band from the PSC, $\text{SES}_n[k]$ is a sum over the bands of interest. The range of possible luminance value pixel options were selected to: 1) separate global flags which are not band

encoded (1-3), from band specific flags (4-6); and 2) give a large dynamic range in luminance for ease of visual display.

Confusion Map Results

In Figure 4 we present the full sky 12 micron (IRAS Band 1) confusion map displayed in galactic coordinates. Increments in galactic longitude [l], (ranging from 0 to 360 degrees) are labeled on the horizontal axis of the image, while galactic latitude [b] (ranging from ± 90 degrees) is in the perpendicular direction. Regions extracted from the PSC to generate this scene have an "exact" selection criteria; only the 12 micron confuse flag bit is set (1000). This criteria will identify sources in the PSC that are confused solely in Band 1. The monochromatic value for all pixels in the image scene results from a luminance mapping using solely the confuse flag (option [4]). A total of 5,013 sources were extracted from the PSC with this source selection criteria. Areas of high source confusion at 12 microns include the galactic plane and the nuclear bulge. In addition, there are many regions located away from the plane ($|b| > 20$) that have been tagged as confused. At extreme latitudes ($|b| > 50$) the majority of these IRAS confused regions (32 %) have positional coincidences with evolved (K0-M0) and/or faint variable stars.

In Figure 5 we present the full sky 25 micron (IRAS Band 2) confusion map displayed in galactic coordinates. Increments in galactic longitude [l], (ranging from 0 to 360 degrees) are labeled on the horizontal axis of the image, while galactic latitude [b] (ranging from ± 90 degrees) is in the perpendicular direction. Regions extracted from the PSC to generate this scene have an "exact" selection criteria; only the 25 micron confuse flag bit is set (0100). This criteria will identify sources in the PSC that are confused solely in Band 2. The monochromatic value for all pixels in the image scene results from a luminance mapping using solely the confuse flag (option [4]). With this selection criteria, 2,468 sources were extracted from the PSC. Similar to what is seen in the 12 micron confusion source map (Fig. 4), regions of severe 25 micron confusion include the galactic plane ($b = 0$) and bulge regions. In addition, the Magellanic Clouds (approximately $l = 270$, $b = -25$), and the Orion HII region complex (approximately $l = 200$, $b = -20$) are prominent regions of confusion at 25 microns.

In Figure 6 we present the full sky 12/25 micron (IRAS Band 1 & 2) confusion map displayed in galactic coordinates. Increments in galactic longitude [l], (ranging from 0 to 360 degrees) are labeled on the horizontal axis of the image, while galactic latitude [b] (ranging from ± 90 degrees) is in the perpendicular direction. Regions selected from the PSC to generate this scene have either a 12 micron or 25 micron confusion bit set (an "any" selection criteria, which will extract any PSC source entry with a 1 present in the 12 or 25 bit). Utilizing a confuse flag luminance mapping (option [4]), the resulting scene (Fig. 6) has a range of image pixel values. With this selection criteria, 10,394 sources were extracted from the PSC.

The described Fortran utility and the all-sky confusion region images (Figures 4 - 6) it generated were used to make a preliminary definition of confused regions (in galactic coordinates):

1. GALACTIC PLANE

$b = \pm 10^\circ$ for $L = \pm 15^\circ$

$b = \pm 5^\circ$ for $15^\circ < L < 85^\circ$ and $-15^\circ > L > -85^\circ$

$b = \pm 3^\circ$ for $85^\circ < L < 100^\circ$ and $-85^\circ > L > -100^\circ$

2. ORION

$10 \times 10^\circ$ centered at $L = 208.23^\circ$, $b = -19.01^\circ$

3. CYGNUS

$2 \times 2^\circ$ centered at $L = 80.33^\circ$, $b = 0.86^\circ$

4. OPHIUCUS

$2 \times 2^\circ$ centered at $L = 353.57^\circ$, $b = 17.31^\circ$

5. LMC

$10 \times 10^\circ$ centered at $L = 303.15^\circ$, $b = -44.40^\circ$

6. SMC

$5 \times 5^\circ$ centered at $L = 278.81^\circ$, $b = -32.31^\circ$

AO Data in Confused Regions

PSC addenda will result from point source extraction analysis of high resolution re-imaged IRAS survey data. High resolution reconstructed IRAS AO data will serve as a major source of validation for PSC addenda. AO data is of intrinsically higher spatial resolution in-scan since many of the AO macros were carried out at fractions of the survey scan rate. To insure consistency and reliability, point source extraction algorithm development will be done on regions with coincident survey and AO coverage. For these reasons one of the first tasks in the definition of confused regions, in terms of actual data, was to compile lists of all the AO data available in high source density regions.

Lists of AOs for the confused regions were extracted from the IRAS AO catalog by UW personnel at Aerospace Corp. Queries for the region ± 10 degrees galactic latitude centered on the galactic plane, and ± 100 degrees galactic longitude, from the galactic center, resulted in lists totalling approximately 400 AO fields. Queries for the Magellanic cloud regions resulted in 49 AOs in 18 fields (SMC) and 204 AOs in 62 fields (LMC). Plots and lists of the AO coverage in the plane region are included in this document as an appendix. Figure 7 is the AO occurrence position plot for the SMC region with overlays which show the extent of the regions included in the AOs whose position markers are circled. A great deal of coverage redundancy is evident on this plot. This spatial redundancy over time will be useful for validation of new or amended entries in the PSC Addenda.

A subset of these AOs was chosen for the first data requests from IPAC to satisfy three interests: 1) AOs were chosen to be coincident with existing survey data already resident at MRC; 2) AOs were chosen because they represent a control region or a particularly difficult or interesting area; and 3) AOs were chosen to give the UW AO processing team exposure to data from a variety of AO macro structures.

To date, we have eight AO fields along the plane at various galactic longitudes, whose centers are ± 0.5 degrees galactic latitude. Table 1 lists the AO fields which have been requested and received, and the AO fields which have been requested and are due to be received by mid-summer.

Some preliminary high-res image reconstruction processing has been done on several AO fields with different macros (scan structures) at UW. So far, two of the AO macro scan structures are presenting problems for the existing high-res reconstruction algorithms. The DPS60D macro has no cross-step, so while there is improved sensitivity in the scanned regions, cross-scan sampling is very sparse. Thus, the reconstructions are much less reliable in the cross-scan dimension than in-scan. Fields scanned with this macro may not be useful in the re-imaging effort. A second problem stems from the fact that the UW/Aerospace pre-processing algorithm depends on spatially adjacent scans for each detector to estimate the detector dark noise. The DSD01A macro has a short scan length which results in a scan pattern over the field which has insufficient same-detector adjacency for the described algorithm to make a reliable estimate. A method of estimating dark bias which is not dependent on the scan pattern will have to be worked out.

To date, we have received survey data for several preliminary regions from IPAC. MRC has a two square degree section centered at $l = 28$ degrees, $b = 0$ degrees ($RA = 280.7$ degrees, $Dec = -3.3$ degrees). We have also received six overlapping sections of survey data in the vicinity of $l = 336$ degrees, $b = 0$ degrees. Each section is three square degrees, and together they cut a swath across the galactic plane. The whole set is centered at $RA = 247.5$ degrees, $Dec = -47$ degrees, extending from 240 to 255 degrees in RA , and from 43.5 to 52.5 degrees in Dec . MRC has reconstructed (without special high-res processing) the $l28, b0$ field, and three of the sections around $l336$, including the on-plane field. MRC has requested from IPAC a ten square degree section of survey footprint data at the galactic center, and we expect to receive these data this summer.

The confusion maps generated by MRC will be used to guide the selection of candidate IRAS data fields for re-imaging. In the event that the confusion maps indicate a candidate region for re-imaging, and good AO coverage does not exist for that region, survey data re-imaging will still be performed. PSC addenda will result, but without the larger certainty that could be added by AO validation.
