Certificate Information

The following Ada implementation was tested and determined to pass ACVC 1.11. Testing was completed on November 29, 1990.

Compiler Name and Version: DACS VAX/VMS to 80186 Bare Ada Cross Compiler System with Rate Monotonic Scheduling, Version 4.6

Host Computer System: VAX 8530 running VMS Version 5.3

Target Computer System: Bare Board iSBC 186/03A

A more detailed description of this Ada implementation is found in section 3.1 of this report.

As a result of this validation effort, Validation Certificate 901129S1.11077 is awarded to DDC International A/S. This certificate expires on March 01, 1993.

This report has been reviewed and is approved.

CHAPTER 1

INTRODUCTION

The Ada implementation described above was tested according to the Ada Validation Procedures [Pro90] against the Ada Standard [Ada83] using the current Ada Compiler Validation Capability (ACVC). This Validation Summary Report (VSR) gives an account of the testing of this Ada implementation. For any technical terms used in this report, the reader is referred to [Pro90]. A detailed description of the ACVC may be found in the current ACVC User's Guide [UG89].

1.1 USE OF THIS VALIDATION SUMMARY REPORT

Consistent with the national laws of the originating country, the Ada Certification Body may make full and free public disclosure of this report. In the United States, this is provided in accordance with the "Freedom of Information Act" (5 U.S.C. #552). The results of this validation apply only to the computers, operating systems, and compiler versions identified in this report.

The organizations represented on the signature page of this report do not represent or warrant that all statements set forth in this report are accurate and complete, or that the subject implementation has no nonconformities to the Ada Standard other than those presented. Copies of this report are available to the public from the AVF which performed this validation or from:

National Technical Information Service
5285 Port Royal Road
Springfield VA 22161

Questions regarding this report or the validation test results should be directed to the AVF which performed this validation or to:

Ada Validation Organization
Institute for Defense Analyses
1801 North Beauregard Street
Alexandria VA 22311

Program Office, August 1990.

1.3 ACVC TEST CLASSES

Compliance of Ada implementations is tested by means of the ACVC. The ACVC contains a collection of test programs structured into six test classes: A, B, C, D, E, and L. The first letter of a test name identifies the class to which it belongs. Class A, C, D, and E tests are executable. Class B and class L tests are expected to produce errors at compile time and link time, respectively.

The executable tests are written in a self-checking manner and produce a PASSED, FAILED, or NOT APPLICABLE message indicating the result when they are executed. Three Ada library units, the packages REPORT and SPRT13, and the procedure CHECK_FILE are used for this purpose. The package REPORT also provides a set of identity functions used to defeat some compiler optimizations allowed by the Ada Standard that would circumvent a test objective. The package SPRT13 is used by many tests for Chapter 13 of the Ada Standard. The procedure CHECK_FILE is used to check the contents of text files written by some of the Class C tests for Chapter 14 of the Ada Standard. The operation of REPORT and CHECK_FILE is checked by a set of executable tests. If these units are not operating correctly, validation testing is discontinued. Class B tests check that a compiler detects illegal language usage. Class B tests are not executable. Each test in this class is compiled and the resulting compilation listing is examined to verify that all violations of the Ada Standard are detected. Some of the class B tests contain legal Ada code which must not be flagged illegal by the compiler. This behavior is also verified.

Class L tests check that an Ada implementation correctly detects violation of the Ada Standard involving multiple, separately compiled units. Errors are expected at link time, and execution is attempted.

In some tests of the ACVC, certain macro strings have to be replaced by implementation-specific values -- for example, the largest integer. A list of the values used for this implementation is provided in Appendix A. In addition to these anticipated test modifications, additional changes may be required to remove unforeseen conflicts between the tests and implementation-dependent characteristics. The modifications required for this implementation are described in section 2.3. For each Ada implementation, a customized test suite is produced by the AVF. This customization consists of making the modifications described in the preceding paragraph, removing withdrawn tests (see section 2.1) and, possibly some inapplicable

tests (see Section 3.2 and [UG89]).

In order to pass an ACVC an Ada implementation must process each test of the customized test suite according to the Ada Standard.

1.4 DEFINITION OF TERMS

Ada Compiler	The software and any needed hardware that have to be added to a given host and target computer system to allow transformation of Ada programs into executable form and execution thereof.
Ada Compiler Validation Capability (ACVC)	The means for testing compliance of Ada implementations, Validation consisting of the test suite, the support programs, the ACVC Capability user's guide and the template for the validation summary (ACVC) report.
Ada Implementation	An Ada compiler with its host computer system and its target computer system.
Ada Validation Facility (AVF)	The part of the certification body which carries out the procedures required to establish the compliance of an Ada implementation.
Ada Validation Organization (AVO)	The part of the certification body that provides technical guidance for operations of the Ada certification system.
Compliance of an Ada Implementation	The ability of the implementation to pass an ACVC version.
Computer System	A functional unit, consisting of one or more computers and associated software, that uses common storage for all or part of a program and also for all or part of the data necessary for the execution of the program; executes user-written or user-designated programs; performs user-designated data manipulation, including arithmetic operations and logic operations; and that can execute programs that modify themselves during execution. A computer system may be a stand-alone unit or may consist of several inter-connected units.
Conformity	Fulfillment by a product, process or service of all requirements specified.

Customer	An individual or corporate entity who enters into an agreement with an AVF which specifies the terms and conditions for AVF services (of any kind) to be performed.
Declaration of Conformance	A formal statement from a customer assuring that conformity is realized or attainable on the Ada implementation for which validation status is realized.
Host Computer System	A computer system where Ada source programs are transformed into executable form.
Inapplicable test	A test that contains one or more test objectives found to be irrelevant for the given Ada implementation.
Operating System	Software that controls the execution of programs and that provides services such as resource allocation, scheduling, input/output control, and data management. Usually, operating systems are predominantly software, but partial or complete hardware implementations are possible.
Target Computer System	A computer system where the executable form of Ada programs are executed.
Validated Ada Compiler	The compiler of a validated Ada implementation.
Validated Ada Implementation	An Ada implementation that has been validated successfully either by AVF testing or by registration [Pro90].
Validation	The process of checking the conformity of an Ada compiler to the Ada programming language and of issuing a certificate for this implementation.
Withdrawn test	A test found to be incorrect and not used in conformity testing. A test may be incorrect because it has an invalid test objective, fails to meet its test objective, or contains erroneous or illegal use of the Ada programming language.

CHAPTER 2

IMPLEMENTATION DEPENDENCIES

2.1 WITHDRAWN TESTS

Some tests are withdrawn by the AVO from the ACVC because they do not conform to the Ada Standard. The following 81 tests had been withdrawn by the Ada Validation Organization (AVO) at the time of validation testing. The rationale for withdrawing each test is available from either the AVO or the AVF. The publication date for this list of withdrawn tests is 90-10-12.

2.2 INAPPLICABLE TESTS

A test is inapplicable if it contains test objectives which are irrelevant for a given Ada implementation. The inapplicability criteria for some tests are explained in documents issued by ISO and the AJPO known as Ada Issues and commonly referenced in the format AI-dddd. For this implementation, the following tests were inapplicable for the reasons indicated; references to Ada Issues are included as appropriate.

The following 201 tests have floating-point type declarations requiring more digits than SYSTEM.MAX_DIGITS:

C24113L..Y (14 tests)	C35705L..Y (14 tests)
C35706L..Y (14 tests)	C35707L..Y (14 tests)
C35708L..Y (14 tests)	C35802L..Z (15 tests)
C45241L..Y (14 tests)	C45321L..Y (14 tests)
C45421L..Y (14 tests)	C45521L..Z (15 tests)
C45524L..Z (15 tests)	C45621L..Z (15 tests)

C45641L..Y (14 tests)

C46012L..Z (15 tests)

C24113I..K (3 TESTS) USE A LINE LENGTH IN THE INPUT FILE WHICH EXCEEDS 126 CHARACTERS.

C35702A, C35713B, C45423B, B86001T, AND C86006H CHECK FOR THE PREDEFINED TYPE SHORT_FLOAT.

C35713D AND B86001Z CHECK FOR A PREDEFINED FLOATING-POINT TYPE WITH A NAME OTHER THAN FLOAT, LONG_FLOAT, OR SHORT_FLOAT.

C35404D, C45231D, B86001X, C86006E, AND CD7101G CHECK FOR A PREDEFINED INTEGER TYPE WITH A NAME OTHER THAN INTEGER, LONG_INTEGER, OR SHORT_INTEGER.

C45531M, C45531N, C45531O, C45531P, C45532M, C45532N, C45532O, AND C45532P CHECK FIXED-POINT OPERATIONS FOR TYPES THAT REQUIRE A SYSTEM.MAX_MANTISSA OF 47 OR GREATER.

C45624A CHECKS THAT THE PROPER EXCEPTION IS RAISED IF MACHINE_OVERFLOW IS FALSE FOR FLOATING POINT TYPES WITH DIGITS 5. FOR THIS IMPLEMENTATION, MACHINE_OVERFLOW IS TRUE.

C45624B CHECKS THAT THE PROPER EXCEPTION IS RAISED IF MACHINE_OVERFLOW IS FALSE FOR FLOATING POINT TYPES WITH DIGITS 6. FOR THIS IMPLEMENTATION, MACHINE_OVERFLOW IS TRUE.

C4A013B CONTAINS THE EVALUATION OF AN EXPRESSION INVOLVING 'MACHINE_RADIX APPLIED TO THE MOST PRECISE FLOATING-POINT TYPE. THIS EXPRESSION WOULD RAISE AN EXCEPTION. SINCE THE EXPRESSION MUST BE STATIC, IT IS REJECTED AT COMPILE TIME.

D56001B USES 65 LEVELS OF BLOCK NESTING WHICH EXCEEDS THE CAPACITY OF THE COMPILER.

C86001F RECOMPILES PACKAGE SYSTEM, MAKING PACKAGE TEXT_IO, AND HENCE PACKAGE REPORT, OBSOLETE. FOR THIS IMPLEMENTATION, THE PACKAGE TEXT_IO IS DEPENDENT UPON PACKAGE SYSTEM.

B86001Y CHECKS FOR A PREDEFINED FIXED-POINT TYPE OTHER THAN DURATION.

C96005B CHECKS FOR VALUES OF TYPE DURATION'BASE THAT ARE OUTSIDE THE RANGE OF DURATION. THERE ARE NO SUCH VALUES FOR THIS IMPLEMENTATION.

CA2009C, CA2009F, BC3204C, AND BC3205D THESE TESTS INSTANTIATE GENERIC UNITS BEFORE THEIR BODIES ARE COMPILED. THIS IMPLEMENTATION CREATES A DEPENDENCE ON GENERIC UNIT AS ALLOWED BY AI-00408 & AI-00530 SUCH THAT A THE COMPILATION OF THE GENERIC UNIT BODIES MAKES THE INSTANTIATING UNITS OBSOLETE.

CD1009C USES A REPRESENTATION CLAUSE SPECIFYING A NON-DEFAULT SIZE FOR A FLOATING-POINT TYPE.

CD2A84A, CD2A84E, CD2A84I..J (2 TESTS), AND CD2A84O USE REPRESENTATION CLAUSES SPECIFYING NON-DEFAULT SIZES FOR ACCESS TYPES.

The following 265 tests check for sequential, text, and direct access files:

CE2102A..C (3)	CE2102G..H (2)	CE2102K	CE2102N..Y (12)
CE2103C..D (2)	CE2104A..D (4)	CE2105A..B (2)	CE2106A..B (2)
CE2107A..H (8)	CE2107L	CE2108A..H (8)	CE2109A..C (3)
CE2110A..D (4)	CE2111A..I (9)	CE2115A..B (2)	
CE2120A..B (2)	CE2201A..C (3)	EE2201D..E (2)	CE2201F..N (9)
CE2203A	CE2204A..D (4)	CE2205A	CE2206A

CE3106A..B (2)	CE3107B	CE3108A..B (2)	CE3109A
CE3110A	CE3111A..B (2)	CE3111D..E (2)	CE3112A..D (4)
CE3114A..B (2)	CE3115A	CE3116A	CE3119A
EE3203A	EE3204A	CE3207A	CE3208A
CE3301A	EE3301B	CE3302A	CE3304A
CE3305A	CE3401A	CE3402A	EE3402B
CE3402C..D (2)	CE3403A..C (3)	CE3403E..F (2)	CE3404B..D (3)
CE3405A	EE3405B	CE3405C..D (2)	CE3406A..D (4)
CE3407A..C (3)	CE3408A..C (3)	CE3409A	CE3409C..E (3)
EE3409F	CE3410A	CE3410C..E (3)	EE3410F
CE3411A	CE3411C	CE3412A	EE3412C
CE3413A..C (3)	CE3414A	CE3602A..D (4)	CE3603A
CE3604A..B (2)	CE3605A..E (5)	CE3606A..B (2)	
CE3704A..F (6)	CE3704M..O (3)	CE3705A..E (5)	CE3706D
CE3706F..G (2)	CE3804A..P (16)	CE3805A..B (2)	CE3806A..B (2)
CE3806D..E (2)	CE3806G..H (2)	CE3904A..B (2)	CE3905A..C (3)
CE3905L	CE3906A..C (3)	CE3906E..F (2)	

CE2103A..B and CE3107A EXPECT THAT NAME_ERROR IS RAISED WHEN AN ATTEMPT IS MADE TO CREATE A FILE WITH AN ILLEGAL NAME; THIS IMPLEMENTATION DOES NOT SUPPORT THE CREATION OF EXTERNAL FILES AND SO RAISES USE_ERROR.

2.3 TEST MODIFICATIONS

Modifications (see section 1.3) were required for 67 tests.

The following tests were split into two or more tests because this

implementation did not report the violations of the Ada Standard in the way expected by the original tests.

B22003A	B26001A	B26002A	B26005A	B28003A	B29001A	B33301B
B35101A	B37106A	B37301B	B37302A	B38003A	B38003B	B38009A
B38009B	B55A01A	B61001C	B61001F	B61001H	B61001I	B61001M
B61001R	B61001W	B67001H	B83A07A	B83A07B	B83A07C	B83E01C
B83E01D	B83E01E	B85001D	B85008D	B91001A	B91002A	B91002B
B91002C	B91002D	B91002E	B91002F	B91002G	B91002H	B91002I
B91002J	B91002K	B91002L	B95030A	B95061A	B95061F	B95061G
B95077A	B97103E	B97104G	BA1001A	BA1101B	BC1109A	BC1109C
BC1109D	BC1202A	BC1202F	BC1202G	BE2210A	BE2413A	

"PRAGMA ELABORATE (REPORT)" has been added at appropriate points in order to solve the elaboration problems for:

C83030C C86007A

CE2103A..B and CE3107A abort with an unhandled exception when USE_ERROR is raised on the attempt to create an external file (see 2.2). The AVO ruled that these tests are to be graded as inapplicable.

CHAPTER 3

PROCESSING INFORMATION

3.1 TESTING ENVIRONMENT

The executable files were prepared on the VAX host computer chapter by chapter. When a chapter was completely processed, the executables were transferred via ethernet to a personal computer (COMPAQ 386 running MS-DOS Version 3.3) acting as a host for an In Circuit Emulation tool (i2ICE). The target was connected via RS232C to second personal computer (COMPAQ 286 running MS-DOS Version 3.3) which acted as a capture device. The second personal computer was connected via ethernet to the VAX.

The DACS VAX/VMS to 80186 Bare Ada Cross Compiler System with Rate Monotonic Scheduling, Version 4.6 was executed on the target board with the following:

- Bare Board iSBC 186/03A
- 8087
- One internal timer
- One serial port
- 128KB RAM

For each chapter, a command file was generated that loaded and executed every program.

Testing of this Ada implementation was conducted at the customer's site by a validation team from the AVF.

3.2 SUMMARY OF TEST RESULTS

An Ada Implementation passes a given ACVC version if it processes each test of the customized test suite in accordance with the Ada Programming Language Standard, whether the test is applicable or inapplicable; otherwise, the Ada Implementation fails the ACVC [Pro90].

For all processed tests (inapplicable and applicable), a result was obtained that conforms to the Ada Programming Language Standard.

a) Total Number of Applicable Tests	3580	
b) Total Number of Withdrawn Tests	81	
c) Processed Inapplicable Tests	509	
d) Non-Processed I/O Tests	0	
e) Non-Processed Floating-Point Precision Tests	0	
f) Total Number of Inapplicable Tests	509	(c+d+e)
g) Total Number of Tests for ACVC 1.11	4170	(a+b+f)

3.3 TEST EXECUTION

Version 1.11 of the ACVC comprises 4170 tests. When this compiler was tested, the tests listed in section 2.1 had been withdrawn because of test errors. The AVF determined that 509 tests were inapplicable to this implementation. All inapplicable tests were processed during validation testing. In addition, the modified tests mentioned in section 2.3 were also processed.

A magnetic tape containing the customized test suite (see section 1.3) was taken on-site by the validation team for processing. The tests were compiled and linked on the host computer system, as appropriate. The executable images were transferred to the target computer system by the communications link described above, and run. The results were captured on the host computer system using the communications link described above.

Testing was performed using command scripts provided by the customer and reviewed by the validation team. See Appendix B for a complete listing of the processing options for this implementation. It also indicates the default options. The options invoked explicitly for validation testing during this test were:

/LIST

The options invoked by default for validation testing during this test were:

/CHECK /CONFIGURATION_FILE = <default file>
/NOTARGET_DEBUG /LIBRARY /NOOPTIMIZE
/NOPROGRESS /NOXREF

Test output, compiler and linker listings, and job logs were captured on magnetic tape and archived at the AVF. Selected listings examined on-site by the validation team were also archived.

APPENDIX A

MACRO PARAMETERS

This appendix contains the macro parameters used for customizing the ACVC. The meaning and purpose of these parameters are explained in [UG89]. The parameter values are presented in two tables. The first table lists the values that are defined in terms of the maximum input-line length, which is 126 the value for \$MAX_IN_LEN--also listed here. These values are expressed here as Ada string aggregates, where "V" represents the maximum input-line length.

Macro Parameter	Macro Value
\$MAX_IN_LEN	126
\$BIG_ID1	(1..V-1 => 'A', V => '1')
\$BIG_ID2	(1..V-1 => 'A', V => '2')
\$BIG_ID3	(1..V/2 => 'A') & '3' & (1..V-1-V/2 => 'A')
\$BIG_ID4	(1..V/2 => 'A') & '4' & (1..V-1-V/2 => 'A')
\$BIG_INT_LIT	(1..V-3 => '0') & "298"
\$BIG_REAL_LIT	(1..V-5 => '0') & "690.0"
\$BIG_STRING1	'"' & (1..V/2 => 'A') & '"'
\$BIG_STRING2	'"' & (1..V-1-V/2 => 'A') & '1' & '"'
\$BLANKS	(1..V-20 => ' ')
\$MAX_LEN_INT_BASED_LITERAL	"2:" & (1..V-5 => '0') & "11:"
\$MAX_LEN_REAL_BASED_LITERAL	"16:" & (1..V-7 => '0') & "F.E:"
\$MAX_STRING_LITERAL	'"' & (1..V-2 => 'A') & '"'

The following table contains the values for the remaining macro parameters.

APPENDIX B

COMPILATION SYSTEM OPTIONS

The compiler options of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this appendix are to compiler documentation and not to this report.

<u>QUALIFIER</u>	<u>DESCRIPTION</u>
/CHECK	Generates run-time constraint checks.
/NOCHECK	
/CONFIGURATION_FILE	Specifies the file used by the compiler.
/DEBUG	Includes symbolic debugging in program library.
/NODEBUG	Does not include symbolic information.
/EXCEPTION_TABLES	Includes/excludes exception handler
/NOEXCEPTION_TABLES	tables from the generated code.
/LIBRARY	Specifies program library used.
/LIST	Writes a source listing on the list file.
/NOLIST	
/OPTIMIZE	Specifies compiler optimization.
/NOOPTIMIZE	
/PROGRESS	Displays compiler progress.
/NOPROGRESS	
/SAVE_SOURCE	Copies source to program library.
/NOSAVE_SOURCE	
/TARGET_DEBUG	Includes Intel debug information.
/NOTARGET_DEBUG	Does not include Intel debug information.
/XREF	Creates a cross reference listing.
/NOXREF	
/UNIT	Assigns a specific unit number to the compilation (must be free and in a sublibrary).

LINKER OPTIONS

The linker options of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this appendix are to linker documentation and not to this report.

<u>QUALIFIER</u>	<u>DESCRIPTION</u>
/OPTIONS	Specifies target link options.
/LIBRARY	The library used in the link.
/LOG	Specifies creation of a log file.
/NOLOG	
/ROOT_EXTRACT	Using non-DDC-I units in the root library.
/NOROOT_EXTRACT	
<unit-name>	Main program to be linked.
[<recompilation-spec>]	Hypothetical recompilation units.
/DEBUG	Links an application for use with
/NODEBUG	the DACS-80x86 Cross Debugger.
/RTS	Includes or excludes the run-time system.
/NORTS	
/NPX	Use of the 80x87 numeric coprocessor.
/NONPX	
/TASK	Maximum number of tasks or non-tasking
/NOTASKS	application.
/PRIORITY	Default task priority.
/TIME_SLICE	Task time slicing.
/NOTIME_SLICE	
/TIMER	Timer resolution.
/RESERVE_STACK	Size of reserve stack.
/NORESERVE_STACK	
/LT_STACK_SIZE	Library task default stack size.
/LT_SEGMENT_SIZE	Library task default segment size.
/MP_STACK_SIZE	Main program stack size.
/MP_SEGMENT_SIZE	Main program segment size.
/SEARCHLIB	Target libraries or object modules to
	include in target link.
/STOP_BEFORE_LINK	Performs Ada link only.
/TASK_STORAGE_SIZE	Tasks default storage size.
/INTERRUPT_ENTRY_TABLE	Range of interrupt entries.
/ENABLE_TASK_TRACE	Enables trace when a task terminates in
	unhandled exception.
/SIZE_OPTIMIZE	Forces the linker to remove units that are
/NOSIZE_OPTIMIZE	not used.
/FLEX	Uses the flexible linker to define the
/NOFLEX	target system link environment.

The qualifiers listed below are only recognized when /FLEX is specified: (/FLEX is default; to avoid FLEX-linking, use /NOFLEX)

<u>QUALIFIER</u>	<u>DESCRIPTION</u>
/EXTRACT	Extracts Ada Object modules.
/NOEXTRACT	
/ELAB	Generates elaboration code.
/NOELAB	
/UCD	Generates User Configurable Data.
/NOUCD	
/TEMPLATE	Specifies template file.

APPENDIX C

APPENDIX F OF THE Ada STANDARD

The only allowed implementation dependencies correspond to implementation-dependent pragmas, to certain machine-dependent conventions as mentioned in Chapter 13 of the Ada Standard, and to certain allowed restrictions on representation clauses. The implementation-dependent characteristics of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this Appendix are to compiler documentation and not to this report. Implementation-specific portions of the package STANDARD, which are not a part of Appendix F, are:

package STANDARD is

type SHORT_INTEGER is range -32_768 .. 32_767;

type INTEGER is range -2_147_483_648 .. 2_147_483_647;

type LONG_INTEGER is range
-16#8000_0000_0000_0000# .. 16#7FFF_FFFF_FFFF_FFFF#;

type FLOAT is digits 6
range -16#0.FFFF_FF#E32 .. 16#0.FFFF_FF#E32;

type LONG_FLOAT is digits 15
range -16#0.FFFF_FFFF_FFFF_F8#E256 ..
16#0.FFFF_FFFF_FFFF_F8#E256;

type DURATION is delta 2#1.0#E-14 range -131_072.0 .. 131_071.0;

end STANDARD;

APPENDIX F IMPLEMENTATION-DEPENDENT CHARACTERISTICS

This appendix describes the implementation-dependent characteristics of DACS-80X86® as required in Appendix F of the Ada Reference Manual (ANSI/MIL-STD-1815A).

F.1 Implementation-Dependent Pragmas

This section describes all implementation defined pragmas.

F.1.1 Pragma INTERFACE_SPELLING

This pragma allows an Ada program to call a non-Ada program whose name contains characters that would be an invalid Ada subprogram identifier. This pragma must be used in conjunction with pragma INTERFACE, i.e., pragma INTERFACE must be specified for the non-Ada subprogram name prior to using pragma INTERFACE_SPELLING.

The pragma has the format:

```
pragma INTERFACE_SPELLING (subprogram name,  
                           string literal);
```

where the subprogram name is that of one previously given in pragma INTERFACE and the string literal is the exact spelling of the interfaced subprogram in its native language. This pragma is only required when the subprogram name contains invalid characters for Ada identifiers.

Example:

```
function RTS_GetDataSegment return Integer;  
  
pragma INTERFACE      (ASM86, RTS_GetDataSegment);  
pragma INTERFACE_SPELLING (RTS_GetDataSegment,  
                           "R1SMGS?GetDataSegment");
```

User's Guide
Implementation-Dependent Characteristics

F.1.2 Pragma LT_SEGMENT_SIZE

This pragma sets the size of a library task stack segment. The pragma has the format:

```
pragma LT_SEGMENT_SIZE (T, N);
```

where T denotes either a task object or task type and N designates the size of the library task stack segment in words.

The library task's stack segment defaults to the size of the library task stack. The size of the library task stack is normally specified via the representation clause (note that T must be a task type)

```
for T'SORAGE_SIZE use N;
```

The size of the library task stack segment determines how many tasks can be created which are nested within the library task. All tasks created within a library task will have their stacks allocated from the same segment as the library task stack. Thus, pragma LT_SEGMENT_SIZE must be specified to reserve space within the library task stack segment so that nested tasks' stacks may be allocated.

The following restrictions are places on the use of LT_SEGMENT_SIZE:

- 1) It must be used only for library tasks.
- 2) It must be placed immediately after the task object or type name declaration.
- 3) The library task stack segment size (N) must be greater than or equal to the library task stack size.

F.1.3 Pragma EXTERNAL_NAME

F.1.3.1 Function

The pragma EXTERNAL_NAME is designed to make permanent Ada objects and subprograms externally available using names supplied by the user.

User's Guide Implementation-Dependent Characteristics

F.1.3.2 Format

The format of the pragma is:

```
pragma EXTERNAL_NAME(<ada_entity>,<external name>)
```

where <ada_entity> should be the name of:

- a permanent object, i.e. an object placed in the permanent pool of the compilation unit - such objects originate in package specifications and bodies only,
- a constant object, i.e. an object placed in the constant pool of the compilation unit - please note that scalar constants are embedded in the code, and composite constants are not always placed in the constant pool, because the constant is not considered constant by the compiler,
- a subprogram name, i.e. a name of a subprogram defined in this compilation unit - please notice that separate subprogram specifications cannot be used, the code for the subprogram **MUST** be present in the compilation unit code,

and where the <external name> is a string specifying the external name associated the <ada_entity>. The <external names> should be unique. Specifying identical spellings for different <ada_entities> will generate errors at compile and/or link time, and the responsibility for this is left to the user. Also the user should avoid spellings similar to the spellings generated by the compiler, e.g. E_XXXXX_YYYYY, P_XXXXX, C_XXXXX and other internal identifications. The target debug type information associated with such external names is the null type.

F.1.3.3 Restrictions

Objects that are local variables to subprograms or blocks cannot have external names associated. The entity being made external ("public") **MUST** be defined in the compilation unit itself. Attempts to name entities from other compilation units will be rejected with a warning.

When an entity is an object the value associated with the symbol will be the relocatable address of the first byte assigned to the object.

F.1.3.4 Example

Consider the following package body fragment:

```
package body example is

  subtype string10 is string(1..10);

  type s is
    record
      len  : integer;
      val  : string10;
    end record;

  global_s : s;
  const_s  : constant string10 := "1234567890";

  pragma EXTERNAL_NAME(global_s, "GLOBAL_S_OBJECT");
  pragma EXTERNAL_NAME(const_s,  "CONST_S");

  procedure handle(...) is
    ...
  end handle;

  pragma EXTERNAL_NAME(handle, "HANDLE_PROC");

  ...

end example;
```

The objects GLOBAL_S and CONST_S will have associated the names "GLOBAL_S_OBJECT" and "CONST_S". The procedure HANDLE is now also known as "HANDLE_PROC". It is allowable to assign more than one external name to an Ada entity.

F.1.3.5 Object Layouts

Scalar objects are laid out as described in Chapter 9. For arrays the object is described by the address of the first element; the array constraint(s) are NOT passed, and therefore it is recommended only to use arrays with known constraints. Non-discriminated records take a consecutive number of bytes, whereas discriminated records may contain pointers to the heap. Such complex objects should be made externally visible, only if the user has thorough knowledge about the layout.

User's Guide Implementation-Dependent Characteristics

F.1.3.6 Parameter Passing

The following section describes briefly the fundamentals regarding parameter passing in connection with Ada subprograms. For more detail, refer to Chapter 9.

Scalar objects are always passed by value. For OUT or IN OUT scalars, code is generated to move the modified scalar to its destination. In this case the stack space for parameters is not removed by the procedure itself, but by the caller.

Composite objects are passed by reference. Records are passed via the address of the first byte of the record. Constrained arrays are passed via the address of the first byte (plus a bitoffset when a packed array). Unconstrained arrays are passed as constrained arrays plus a pointer to the constraints for each index in the array. These constraints consist of lower and upper bounds, plus the size in words or bits of each element depending if the value is positive or negative respectively. The user should study an appropriate disassembler listing to thoroughly understand the compiler calling conventions.

A function (which can only have IN parameters) returns its result in register(s). Scalar results are registers/float registers only; composite results leave an address in some registers and the rest, if any, are placed on the stack top. The stack still contains the parameters in this case (since the function result is likely to be on the stack), so the caller must restore the stack pointer to a suitable value, when the function call is dealt with. Again, disassemblies may guide the user to see how a particular function call is to be handled.

F.1.4 Pragma INTERRUPT_HANDLER

This pragma will cause the compiler to generate fast interrupt handler entries instead of the normal task calls for the entries in the task in which it is specified. It has the format:

```
pragma INTERRUPT_HANDLER;
```

The pragma must appear as the first thing in the specification of the task object. The task must be specified in a package and not a procedure. See Section F.6.2.3 for more details and restrictions on specifying address clauses for task entries.

User's Guide Implementation-Dependent Characteristics

F.2 Implementation-Dependent Attributes

No implementation-dependent attributes are defined.

F.3 Package SYSTEM

The specifications of package SYSTEM for all DACS-80x86 in Real Address Mode and DACS-80286PM systems are identical except that type Name and constant System_Name vary:

Compiler System	System_Name
DACS-8086	iAPX86
DACS-80186	iAPX186
DACS-80286 Real Mode	iAPX286
DACS-80286 Protected Mode	iAPX286_PM
DACS-80386 Real Mode	iAPX386

Below is package system for DACS-8086.

package System is

```
type      Word      is new Integer;
type      DWord     is new Long_integer;

type      UnsignedWord is range 0..65535;
for       UnsignedWord'SIZE use 16;

type      byte is range 0..255;
for       byte'SIZE use 8;

subtype SegmentId    is UnsignedWord;

type      Address    is
  record
    offset : UnsignedWord;
    segment : SegmentId;
  end record;

subtype Priority    is Integer range 0..31;

type Name          is (iAPX86);

SYSTEM_NAME       : constant Name := iAPX86;
```

User's Guide
Implementation-Dependent Characteristics

```
STORAGE_UNIT : constant      := 16;
MEMORY_SIZE   : constant      := 1_048_576;
MIN_INT       : constant      := -2_147_483_647-1;
MAX_INT       : constant      := 2_147_483_647;
MAX_DIGITS    : constant      := 15;
MAX_MANTISSA  : constant      := 31;
FINE_DELTA    : constant      := 2#1.0#E-31;
TICK          : constant      := 0.000_000_125;

type Interface_language is
    (ASM86,      PLM86,      C86,      C86_REVERSE,
     ASM_ACF,    PLM_ACF,    C_ACF,    C_REVERSE_ACF,
     ASM_NOACF,  PLM_NOACF,  C_NOACF,  C_REVERSE_NOACF);

type ExceptionId is record
    unit_number : UnsignedWord;
    unique_number : UnsignedWord;
end record;

type TaskValue is new Integer;
type AccTaskValue is access TaskValue;
type SemaphoreValue is new Integer;

type Semaphore is record
    counter : Integer;
    first : TaskValue;
    last : TaskValue;
    SQNext : SemaphoreValue;
    -- only used in HDS.
end record;

InitSemaphore : constant Semaphore := Semaphore'(1,0,0,0);

end System;
```

User's Guide Implementation-Dependent Characteristics

The package SYSTEM specification for DACS-80386PM package system is:

package System is

```
type Word is new Short_Integer;
type DWord is new Integer;
type QWord is new Long_Integer;

type UnsignedWord is range 0..65535;
for UnsignedWord'SIZE use 16;
type UnsignedDWord is range 0..16#FFFF_FFFF#;
for UnsignedDWord'SIZE use 32;
type Byte is range 0..255;
for Byte'SIZE use 8;

subtype SegmentId is UnsignedWord;

type Address is
  record
    offset : UnsignedDWord;
    segment : SegmentId;
  end record;

for Address use
  record
    offset at 0 range 0..31;
    segment at 2 range 0..15;
  end record;

subtype Priority is Integer range 0..31;

type Name is (iAPX386_PM);

SYSTEM_NAME : constant Name := iAPX386_PM;
STORAGE_UNIT : constant := 16;
MEMORY_SIZE : constant := 16#1_0000_0000#;
MIN_INT : constant := -16#8000_0000_0000_0000#;
MAX_INT : constant := 16#7FFF_FFFF_FFFF_FFFF#;
MAX_DIGITS : constant := 15;
MAX_MANTISSA : constant := 31;

FINE_DELTA : constant := 2#1.0#E-31;
TICK : constant := 0.000_000_062_5;

type Interface language is
  (ASM86, PLM86, C86, C86_REVERSE,
   ASM_ACF, PLM_ACF, C_ACF, C_REVERSE_ACF,
   ASM_NOACF, PLM_NOACF, C_NOACF, C_REVERSE_NOACF);
```

User's Guide
Implementation-Dependent Characteristics

```
type ExceptionId is record
    unit_number    : UnsignedDWord;
    unique_number  : UnsignedDWord;
end record;

type TaskValue    is new Integer;
type AccTaskValue is access TaskValue;
type SemaphoreValue is new Integer;

type Semaphore is record
    counter      : Integer;
    first, last  : TaskValue;
    SQNext       : SemaphoreValue;
                -- only used in HDS.
end record;

InitSemaphore : constant Semaphore := Semaphore'(1,0,0,0);

end System;
```

F.4 Representation Clauses

The representation clauses that are accepted are described below. Note that representation specifications can be given on derived types too.

Throughout this subsection, references are made to the size of objects. This number may depend on the compiler variant; in such cases two figures are quoted, i.e. 16/32. The first figure refers to all versions of DACS-80x86 except DACS-80386 PM, to which the last figure refers.

F.4.1 Length Clause

Four kinds of length clauses are accepted.

Size specifications:

The size attribute for a type T is accepted in the following cases:

- If T is a discrete type then the specified size must be greater than or equal to the number of bits needed to represent a value of the type, and less than or equal to 16/32. Note that when the number of bits needed to hold any value of the type is calculated, the range is extended to include 0 if necessary, i.e. the range 3..4 cannot be represented in 1 bit, but needs 3 bits.
- If T is a fixed point type, then the specified size must be greater than or equal to the smallest number of bits needed to hold any value of the fixed point type, and less than 16/32 bits. Note that the Reference Manual permits a representation, where the lower bound and the upper bound is not representable in the type. Thus the type

type FIX is delta 1.0 range -1.0 .. 7.0;

is representable in 3 bits. As for discrete types, the number of bits needed for a fixed point type is calculated using the range of the fixed point type possibly extended to include 0.0.

- If T is a floating point type, an access type or a task type the specified size must be equal to the number of bits used to represent values of the type (floating points: 32 or 64, access types : 32/48 bits and task types : 16/32 bits).
- If T is a record type the specified size must be greater than or equal to the minimal number of bits used to represent values of the type per default.

User's Guide Implementation-Dependent Characteristics

- If T is an array type the size of the array must be static, i.e. known at compile time and the specified size must be equal to the minimal number of bits used to represent values of the type per default.

Furthermore, the size attribute has only effect if the type is part of a composite type.

```
type BYTE is range 0..255;  
for BYTE'size use 8;  
SIXTEEN : BYTE                -- one word allocated  
EIGHT  : array(1.4) of BYTE   -- one byte per element
```

Collection size specifications:

Using the STORAGE_SIZE attribute on an access type will set an upper limit on the total size of objects allocated in the collection allocated for the access type. If further allocation is attempted, the exception STORAGE_ERROR is raised. The specified storage size must be less than or equal to INTEGER'LAST.

Task storage size :

When the STORAGE_SIZE attribute is given on a task type, the task stack area will be of the specified size.

Small specifications :

Any value of the SMALL attribute less than the specified delta for the fixed point type can be given.

User's Guide Implementation-Dependent Characteristics

F.4.2 Enumeration Representation Clauses

Enumeration representation clauses may specify representations in the range of `-16#7FFF# .. 16#7FFE#`. An enumeration representation clause may be combined with a length clause. If an enumeration representation clause has been given for a type the representational values are considered when the number of bits needed to hold any value of the type is evaluated. Thus the type

```
type ENUM is (A,B,C);  
for ENUM use (1,3,5);
```

needs 3 bits not 2 bits to represent any value of the type.

F.4.3 Record Representation Clauses

When component clauses are applied to a record type the following restrictions and interpretations are imposed :

- All values of the component type must be representable within the specified number of bits in the component clause.
- If the component type is either a discrete type a fixed point type, or an array type with a discrete type other than `LONG_INTEGER`, or a fixed point type as element type, then the component is packed into the specified number of bits (see however the restriction in the paragraph above), and the component may start at any bit boundary.
- If the component type is not one of the types specified in the paragraph above, it must start at a storage unit boundary, a storage unit being 16 bits, and the default size calculated by the compiler must be given as the bit width, i.e. the component must be specified as

```
component at N range 0 .. 16 * M-1
```

where N specifies the relative storage unit number (0,1,...) from the beginning of the record, and M the required number of storage units (1,2,...).

- The maximum bit width for components of scalar types is 16/32.
- A record occupies an integral number of storage units (even though a record may have fields that only define an odd number of bytes)
- A record may take up a maximum of 32 Kbits

User's Guide Implementation-Dependent Characteristics

- If the component type is an array type with a discrete type other than LONG INTEGER or a fixed point type as element type, the given bit width must be divisible by the length of the array, i.e. each array element will occupy the same number of bits.

If the record type contains components which are not covered by a component clause, they are allocated consecutively after the component with the value. Allocation of a record component without a component clause is always aligned on a storage unit boundary. Holes created because of component clauses are not otherwise utilized by the compiler.

F.4.3.1 Alignment Clauses

Alignment clauses for records are implemented with the following characteristics:

- If the declaration of the record type is done at the outermost level in a library package, any alignment is accepted.
- If the record declaration is done at a given static level higher than the outermost library level, i.e., the permanent area), only word alignments are accepted.
- Any record object declared at the outermost level in a library package will be aligned according to the alignment clause specified for the type. Record objects declared elsewhere can only be aligned on a word boundary. If the record type is associated with a different alignment, an error message will be issued.
- If a record type with an associated alignment clause is used in a composite type, the alignment is required to be one word; an error message is issued if this is not the case.

F.5 Implementation-Dependent Names for Implementation-Dependent Components

None defined by the compiler.

User's Guide Implementation-Dependent Characteristics

F.6 Address Clauses

This section describes the implementation of address clauses and what types of entities may have their address specified by the user.

F.6.1 Objects

Address clauses are supported for scalar and composite objects whose size can be determined at compile time. The address value must be static. The given address is the virtual address.

F.6.2 Task Entries

The implementation supports two methods to equate a task entry to a hardware interrupt through an address clause:

- 1) Direct transfer of control to a task accept statement when an interrupt occurs bypassing the DMS/OS kernel. This form requires the use of pragma INTERRUPT_HANDLER. These handlers are called fast interrupt handlers.
- 2) Mapping of a signal onto a normal conditional entry call. This form allows the interrupt entry to be called from other tasks (without special actions), as well as being called when a signal occurs.

F.6.2.1 Fast Interrupt Tasks

Directly transferring control to an accept statement when an interrupt occurs requires the implementation dependent pragma INTERRUPT_HANDLER to tell the compiler that the task is an interrupt handler.

F.6.2.2 Features

Fast interrupt tasks provide the following features:

- 1) Provide the fastest possible response time to an interrupt.
- 2) Allow entry calls to other tasks during interrupt servicing.

User's Guide

Implementation-Dependent Characteristics

- 3) Allow procedure and function calls during interrupt servicing.
- 4) Does not require its own stack to be allocated.
- 5) Can be coded in packages with other declarations so that desired visibility to appropriate parts of the program can be achieved.
- 6) May have multiple accept statements in a single fast interrupt task, each mapped to a different interrupt. If more than one interrupt is to be serviced by a single fast interrupt task, the accept statements should simply be coded consecutively. See example 2 to show how this is done. Note that no code outside the accept statements will ever be executed.

F.6.2.3 Limitations

By using the fast interrupt feature, the user is agreeing to place certain restrictions on the task in order to speed up the software response to the interrupt. Consequently, use of this method to capture interrupts is much faster than the normal method.

The following limitations are placed on a fast interrupt task:

- 1) It must be a task object, not a task type.
- 2) The pragma must appear first in the specification of the task object.
- 3) All entries of the task object must be single entries (no families) with no parameters.
- 4) The entries must not be called from any task.
- 5) The body of the task must not contain any statements outside the accept statement(s). A loop statement may be used to enclose the accept(s), but this is meaningless because no code outside the accept statements will be executed.
- 6) The task may make one entry call to another task for every handled interrupt, but the call must be single and parameterless and must be made to a normal task, not another fast interrupt task.
- 7) The task may only reference global variables; no data local to the task may be defined.

User's Guide Implementation-Dependent Characteristics

- 8) The task must be declared in a library package, i.e., at the outermost level of some package.
- 9) Explicit saving of NPX state must be performed by the user within the accept statement if such state saving is required.

F.6.2.4 Making Entry Calls to Other Tasks

Fast interrupt tasks can make entry calls to other normal tasks as long as the entries are single (no indexes) and parameterless.

If such an entry call is made and there is a possibility of the normal task not being ready to accept the call, the entry call can be queued to the normal task's entry queue. This can be forced by using the normal Ada conditional entry call construct shown below:

```
accept E do
  select
    T.E;
  else
    null;
  end select;
end E;
```

Normally, this code sequence means make the call and if the task is not waiting to accept it immediately, cancel the call and continue. In the context of a fast interrupt task, however, the semantics of this construct are modified slightly to force the queuing of the entry call.

If an unconditional entry call is made and the called task is not waiting at the corresponding accept statement, then the interrupt task will wait at the entry call. Alternatively, if a timed entry call is made and the called task does not accept the call before the delay expires, then the call will be dropped. The conditional entry call is the preferred method of making task entry calls from fast interrupt handlers because it allows the interrupt service routine to complete straight through and it guarantees queueing of the entry call if the called task is not waiting.

When using this method, make sure that the interrupt is included in the `/INTERRUPT_ENTRY_TABLE` specified at link time. See Section 7.2.15 for more details.

User's Guide Implementation-Dependent Characteristics

F.6.2.5 Implementation of Fast Interrupts

Fast interrupt tasks are not actually implemented as true Ada tasks. Rather, they can be viewed as procedures that consist of code simply waiting to be executed when an interrupt occurs. They do not have a state, priority, or a task control block associated with them, and are not scheduled to "run" by the run-time system.

Since a fast interrupt handler is not really a task, to code it in a loop of somekind is meaningless because the task will never loop; it will simply execute the body of the accept statement whenever the interrupt occurs. However, a loop construct could make the source code more easily understood and has no side effects except for the generation of the executable code to implement to loop construct.

F.6.2.6 Flow of Control

When an interrupt occurs, control of the CPU is transferred directly to the accept statement of the task. This means that the appropriate slot in the interrupt vector table is modified to contain the address of the corresponding fast interrupt accept statement.

Associated with the code for the accept statement is

at the very beginning:
code that saves registers

at the very end:
code that restores registers followed by an IRET instruction.

Note that if the interrupt handler makes an entry call to another task, the interrupt handler is completed through the IRET before the rendezvous is actually completed. After the rendezvous completes, normal Ada task priority rules will be obeyed, and a task context switch may occur.

Normally, the interrupting device must be reenabled by receiving End-Of-Interrupt messages. These can be sent from machine code insertion statements as demonstrated in Example 7.

F.6.2.7 Saving NPX State

If the interrupt handler will perform floating point calculations and the state of the NPX must be saved because other tasks also use the numeric coprocessor, calls to the appropriate

User's Guide Implementation-Dependent Characteristics

save/restore routines must be made in the statement list of the accept statement. These routines are located in package `RTS_EntryPoints` and are called `RTS_Store_NPX_State` and `RTS_Restore_NPX_State`. See example 6 for more information.

F.6.2.8 Storage Used

This section details the storage requirements of fast interrupt handlers.

F.6.2.9 Stack Space

A fast interrupt handler executes off the stack of the task executing at the time of the interrupt. Since a fast interrupt handler is not a task it does not have its own stack.

Since no local data or parameters are permitted, use of stack space is limited to procedure and function calls from within the interrupt handler.

F.6.2.10 Run-Time System Data

No task control block (TCB) is created for a fast interrupt handler.

If the fast interrupt handler makes a task entry call, an entry in the `_CD_INTERRUPT_VECTOR` must be made to allocate storage for the queuing mechanism. This table is a run-time system data structure used for queuing interrupts to normal tasks. Each entry is only 10 words for 80386 protected mode compilers and 5 words for all other compiler systems. This table is created by the linker and is constrained by the user through the linker qualifier `/INTERRUPT_ENTRY_TABLE`. For more information, see Section F.6.2.1 on linking an application with fast interrupts.

If the state of the NPX is saved by user code (see Section F.6.2.7), it is done so in the NPX save area of the TCB of the task executing at the time of the interrupt. This is appropriate because it is that task whose NPX state is being saved.

F.6.3 Building an Application with Fast Interrupt Tasks

This section describes certain steps that must be followed to build an application using one or more fast interrupt handlers.

User's Guide Implementation-Dependent Characteristics

F.6.3.1 Source Code

The pragma `INTERRUPT_HANDLER` which indicates that the interrupt handler is the fast form of interrupt handling and not the normal type, must be placed in the task specification as the first statement.

When specifying an address clause for a fast interrupt handler, the offset should be the interrupt number, not the offset of the interrupt in the interrupt vector. The segment is not applicable (although a zero value must be specified) as it is not used by the compiler for interrupt addresses. The compiler will place the interrupt vector into the `INTERRUPTVECTORTABLE` segment. For real address mode programs, the interrupt vector must always be in segment 0 at execution time (see *). For protected mode programs, the user specifies the interrupt vector location at build time.

Calls to `RTS_Store_NPX_State` and `RTS_Restore_NPX_State` must be included if the state of the numeric coprocessor must be saved when the fast interrupt occurs. These routines are located in package `RTS_EntryPoints` in the root library. See example 6 for more information.

F.6.3.2 Compiling the Program

No special compilation options are required.

F.6.3.3 Linking the Program

Since fast interrupt tasks are not real tasks, they do not have to be accounted for when using the `/TASKS` qualifier at link time. In fact, if there are no normal tasks in the application, the program can be linked without `/TASKS`.

This also means that the linker options `/LT_STACK_SIZE`, `/LT_SEGMENT_SIZE`, `/MP_SEGMENT_SIZE`, and `/TASK_STORAGE_SIZE` do not apply to fast interrupt tasks, except to note that a fast interrupt task will execute off the stack of the task running at the time of the interrupt.

- * This placement can be accomplished at locate time by specifying the address to locate the `INTERRUPTVECTORTABLE` segments with the `LOC86` command, or at run time, by having the startup code routine of the UCC copy down the `INTERRUPTVECTORTABLE` segment to segment 0.

User's Guide Implementation-Dependent Characteristics

If an entry call is made by a fast interrupt handler the interrupt number must be included in the `/INTERRUPT_ENTRY_TABLE` qualifier at link time. This qualifier builds a table in the run-time system data segment to handle entry calls of interrupt handlers. The table is indexed by the interrupt number, which is bounded by the low and high interrupt numbers specified at link time.

F.6.3.4 Locating/Building the Program

For real-address mode programs, no special actions need be performed at locate-time; the compiler creates the appropriate entry in the `INTERRUPTVECTORTABLE` segment. This segment must be at segment 0 before the first interrupt can occur.

For protected mode programs, an interrupt gate must be added and a table entry must be added to the interrupt descriptor table (IDT) for each interrupt serviced by a fast interrupt handler. The value to be put into the build file is the address of the routine that is to be vectored to when the interrupt occurs. This is specified by a label produced by the code generator which can be discerned by disassembling the package specification that contains the interrupt task. For an interrupt handler servicing decimal interrupt 10, the label would be `_AIH_00010`. "AIH" means Ada Interrupt Handler. An example of creating a fast interrupt handler for a protected mode program is shown in example 5.

F.6.4 Examples

These examples illustrate how to write fast interrupt tasks and then how to build the application using the fast interrupt tasks.

F.6.4.1 Example 1

This example shows how to code a fast interrupt handler that does not make any task entry calls, but simply performs some interrupt handling code in the accept body.

User's Guide Implementation-Dependent Characteristics

Ada source:

```
with System;
package P is

    <potentially other declarations>

    task Fast_Interrupt_Handler is
        pragma INTERRUPT_HANDLER;
        entry E;
        for E use at (segment => 0, offset => 10);
    end;

    <potentially other declarations>

end P;

package body P is

    <potentially other declarations>

    task body Fast_Interrupt_Handler is
    begin
        accept E do
            <handle interrupt>
        end E;
    end;

    <potentially other declarations>

end P;

with P;
procedure Example_1 is
begin
    <main program>
end Example_1;
```

Compilation and Linking:

```

$ ada/link Example_1      ! Note: no other tasks in the
                          ! system in this example
```

F.6.4.2 Example 2

This example shows how to write a fast interrupt handler that services more than one interrupt.

User's Guide Implementation-Dependent Characteristics

Ada source:

```
with System;
package P is

    task Fast_Interrupt_Handler is
        pragma INTERRUPT_HANDLER;

        entry E1;
        entry E2;
        entry E3;

        for E1 use at (segment => 0, offset => 5);
        for E2 use at (segment => 0, offset => 9);
        for E3 use at (segment => 0, offset => 11);

    end;

end P;

package body P is

    task body Fast_Interrupt_Handler is
    begin
        accept E1 do
            <service interrupt 5>
        end E1;

        accept E2 do
            <service interrupt 9>
        end E2;

        accept E3 do
            <service interrupt 11>
        end E3;
    end;

end P;
```

Compilation and Linking:

```
$ ada Example_2
$ ada/link/tasks Example_2 ! assumes application also
                           ! has normal tasks (not
                           ! shown)
```

User's Guide
Implementation-Dependent Characteristics

F.6.4.3 Example 3

This example shows how to access global data and make a procedure call from within a fast interrupt handler.

Ada source:

```
with System;
package P is

    A : Integer;

    task Fast_Interrupt_Handler is
        pragma INTERRUPT_HANDLER;
        entry E;
        for E use at (segment => 0, offset => 16#127#);
    end;

end P;

package body P is

    B : Integer;

    procedure P (X : in out Integer) is
    begin
        X := X + 1;
    end;

    task body Fast_Interrupt_Handler is
    begin
        accept E do
            A := A + B;
            P (A);
        end E;
    end;

end P;
```

Compilation and Linking:

```
$ ada      Example_3
$ ada/link Example_3
```

F.6.4.4 Example 4

This example shows how to make a task entry call and force it to be queued if the called task is not waiting at the accept at the time of the call.

Note that the application is linked with /TASKS=2, where the tasks are T and the main program. Since the fast interrupt handler is making an entry call to T, the techniques used guarantee that it will be queued, if necessary. This is accomplished by using the conditional call construct in the accept body of the fast interrupt handler and by including the interrupt in the /INTERRUPT_ENTRY_TABLE at link time.

Ada source:

```
with System;
package P is

    task Fast_Interrupt_Handler is
        pragma INTERRUPT_HANDLER;
        entry E;
        for E use at (segment => 0, offset => 8);
    end;

    task T is
        entry E;
    end;

end P;

package body P is

    task body Fast_Interrupt_Handler is
    begin
        accept E do
            select
                T.E;
            else
                null;
            end select;
        end E;
    end;
```

User's Guide Implementation-Dependent Characteristics

```
task body T is
begin
  loop
    select
      accept E;
    or
      delay 3.0;
    end select;
  end loop;
end;

end P;
```

Compilation and Linking:

```
$ ada Example_4
$ ada/link/tasks=2/interrupt_entry_table=(8,8) Example_4
```

F.6.4.5 Example 5

This example shows how to build an application for 80386 protected mode programs using fast interrupt handlers.

For protected mode programs, special entries must be made in the build file to modify the interrupt vector.

Ada source:

```
with System;
package P is

  task Fast_Interrupt_Handler is
    pragma INTERRUPT_HANDLER;
    entry E;
    for E use at (segment => 0, offset => 17);
  end;

end P;

package body P is

  task body Fast_Interrupt_Handler is
  begin
    accept E do
      null;
    end E;
  end;

end P;
```

F.6.4.6 Example 6

This example shows how to save and restore the state of the numeric coprocessor from within a fast interrupt handler. This would be required if other tasks are using the coprocessor to perform floating point calculations and the fast interrupt handler also will use the coprocessor.

Note that the state of the NPX is saved in the task control block of the task executing at the time of the interrupt.

Ada source:

```
with System;
package P is

    task Fast_Interrupt_Handler is
        pragma INTERRUPT_HANDLER;
        entry E;
        for E use at (segment => 0, offset => 25);
    end;

end P;

with RTS_EntryPoints;
package body P is

    task body Fast_Interrupt_Handler is
    begin
        accept E do
            RTS_EntryPoints.Store_NPX_State;

            <user code>

            RTS_EntryPoints.Restore_NPX_State;
        end E;
    end;

end P;
```

Compilation and Linking:

$ ada Example_6
$ ada/link/npx/tasks Example_6
```

F.6.4.7 Example 7

This example shows how to send an End-Of-Interrupt message as the last step in servicing the interrupt.

Ada source:

```
with System;
package P is

    task Fast_Interrupt_Handler is
        pragma INTERRUPT_HANDLER;
        entry E;
        for E use at (segment => 0, offset => 5);
    end;

end P;

with Machine_Code; use Machine_Code;
package body P is

    procedure Send_EOI is
    begin
        machine_instruction'
            (register_immediate, m_MOV, AL, 16#66#);
        machine_instruction'
            (immediate_register, m_OUT, 16#0e0#, AL);
    end;
    pragma inline (Send_EOI);

    task body Fast_Interrupt_Handler is
    begin
        accept E do
            <user code>
            Send_EOI;
        end E;
    end;

end P;
```

F.6.5 Normal Interrupt Tasks

"Normal" interrupt tasks are the standard method of servicing interrupts. In this case the interrupt causes a conditional entry call to be made to a normal task.

F.6.5.1 Features

Normal interrupt tasks provide the following features:

- 1) Local data may be defined and used by the interrupt task.
- 2) May be called by other tasks with no restrictions.
- 3) Can call other normal tasks with no restrictions.
- 4) May be declared anywhere in the Ada program where a normal task declaration is allowed.

F.6.5.2 Limitations

Mapping of an interrupt onto a normal conditional entry call puts the following constraints on the involved entries and tasks:

- 1) The affected entries must be defined in a task object only, not a task type.
- 2) The entries must be single and parameterless.

F.6.5.3 Implementation of Normal Interrupt Tasks

Normal interrupt tasks are standard Ada tasks. The task is given a priority and runs as any other task, obeying the normal priority rules and any time-slice as configured by the user.

F.6.5.4 Flow of Control

When an interrupt occurs, control of the CPU is transferred to an interrupt service routine generated by the specification of the interrupt task. This routine preserves the registers and calls the run-time system, where the appropriate interrupt task and entry are determined from the information in the `_CD_INTERRUPT_VECTOR` table and a conditional entry call is made.

If the interrupt task is waiting at the accept statement that corresponds to the interrupt, then the interrupt task is scheduled for execution upon return from the interrupt service routine and the call to the run-time system is completed. The interrupt service routine will execute an `IRET`, which reenables interrupts, and execution will continue with the interrupt task.

If the interrupt task is not waiting at the accept statement that corresponds to the interrupt, and the interrupt task is not in the body of the accept statement that corresponds to the interrupt, then the entry call is automatically queued to the task, and the call to the run-time system is completed.

If the interrupt task is not waiting at the accept statement that corresponds to the interrupt, and the interrupt task is executing in the body of the accept statement that corresponds to the interrupt, then the interrupt service routine will NOT complete until the interrupt task has exited the body of the accept statement. During this period, the interrupt will not be serviced, and execution in the accept body will continue with interrupts disabled. Users are cautioned that if from within the body of the accept statement corresponding to an interrupt, an unconditional entry call is made, a delay statement is executed, or some other non-deterministic action is invoked, the result will be erratic and will cause non-deterministic interrupt response.

Example 4 shows how End-Of-Interrupt messages may be sent to the interrupting device.

F.6.5.5 Saving NPX State

Because normal interrupt tasks are standard tasks, the state of the NPX numeric coprocessor is saved automatically by the run-time system when the task executes. Therefore, no special actions are necessary by the user to save the state.

User's Guide Implementation-Dependent Characteristics

F.6.5.6 Storage Used

This section describes the storage requirements of standard interrupt tasks.

F.6.5.7 Stack Space

A normal interrupt task is allocated its own stack and executes off that stack while servicing an interrupt. See the appropriate sections of this User's Guide on how to set task stack sizes.

F.6.5.8 Run-Time System Data

A task control block is allocated for each normal interrupt task via the /TASKS qualifier at link time.

During task elaboration, an entry is made in the run-time system `_CD_INTERRUPT_VECTOR` table to "define" the standard interrupt. This mechanism is used by the run-time system to make the conditional entry call when the interrupt occurs. This means that the user is responsible to include all interrupts serviced by normal interrupt tasks in the `/INTERRUPT_ENTRY_TABLE` qualifier at link time.

F.6.6 Building an Application with Normal Interrupt Tasks

This section describes how to build an application that uses standard Ada tasks to service interrupts.

F.6.6.1 Source Code

No special pragmas or other such directives are required to specify that a task is a normal interrupt task. If it contains interrupt entries, then it is a normal interrupt task by default.

When specifying an address clause for a normal interrupt handler, the offset should be the interrupt number, not the offset of the interrupt in the interrupt vector. The segment is not applicable (although some value must be specified) because it is not used by the compiler for interrupt addresses. The compiler will place the interrupt vector into the `INTERRUPTVECTORTABLE` segment. For real address mode programs, the interrupt vector must always be in segment 0 at execution time. This placement can be accomplished by specifying the address to locate the `INTERRUPTVECTORTABLE` segment with the `loc86` command, or at run

User's Guide Implementation-Dependent Characteristics

time, by having the startup code routine of the UCC copy down the INTERRUPTVECTORTABLE segment to segment 0 and the compiler will put it there automatically. For protected mode programs, the user specifies the interrupt vector location at build time.

F.6.6.2 Compiling the Program

No special compilation options are required.

F.6.6.3 Linking the Program

The interrupt task must be included in the /TASKS qualifier. The link options /LT_STACK_SIZE, /LT_SEGMENT_SIZE, /MP_SEGMENT_SIZE, and /TASK_STORAGE_SIZE apply to normal interrupt tasks and must be set to appropriate values for your application.

Every normal interrupt task must be accounted for in the /INTERRUPT_ENTRY_TABLE qualifier. This qualifier causes a table to be built in the run-time system data segment to handle interrupt entries. In the case of standard interrupt tasks, this table is used to map the interrupt onto a normal conditional entry call to another task.

F.6.6.4 Locating/Building the Program

For real-address mode programs, no special actions need be performed at locate-time; the compiler creates the appropriate entry in the INTERRUPTVECTORTABLE segment. This segment must be located at segment 0 before the occurrence of the first interrupt.

For protected mode programs, an interrupt gate must be added and a table entry must be added to the interrupt descriptor table (IDT) for each interrupt serviced by a fast interrupt handler. The value to be put into the build file is the place in the code that is to be vectored to when the interrupt occurs. This is specified by a label produced by the code generator which can be discerned by disassembling the package specification that contains the interrupt task. For an interrupt handler servicing decimal interrupt 12, the label would be _AIH_00012. "AIH" means Ada Interrupt Handler. An example of creating a normal interrupt handler for a protected mode program is shown in example 3.

F.6.7 Examples

These examples illustrate how to write normal interrupt tasks and then how to build the application using them.

F.6.7.1 Example 1

This example shows how to code a simple normal interrupt handler.

Ada source:

```
with System;
package P is

    task Normal_Interrupt_Handler is
        entry E;
        for E use at (segment => 0, offset => 10);
    end;

end P;

package body P is

    task body Normal_Interrupt_Handler is
    begin
        accept E do
            <handle interrupt>
        end E;
    end;

end P;

with P;
procedure Example_1 is
begin
    <main program>
end Example_1;
```

Compilation and Linking:

```
$ ada Example_1
$ ada/link/tasks=2/interrupt_entry_table=(10,10) Example_1
```

User's Guide
Implementation-Dependent Characteristics

F.6.7.2 Example 2

This example shows how to write a normal interrupt handler that services more than one interrupt and has other standard task entries.

Ada source:

```
with System;
package P is

    task Normal_Task is

        entry E1;
        entry E2;           -- standard entry
        entry E3;

        for E1 use at (segment => 0, offset => 7);
        for E3 use at (segment => 0, offset => 9);

    end;

end P;

package body P is

    task body Normal_Task is
    begin
        loop
            select
                accept E1 do
                    <service interrupt 7>
                end E1;
            or
                accept E2 do
                    <standard rendezvous>
                end E2;
            or
                accept E3 do
                    <service interrupt 9>
                end E3;
            end select;
        end loop;
    end Normal_Task;

end P;
```

Compilation and Linking:

```
$ ada Example_2
$ ada/link/tasks/interrupt_entry_table=(7,9) Example_2
```

User's Guide Implementation-Dependent Characteristics

F.6.7.3 Example 3

This example shows how to build an application for 80386 protected mode programs using normal interrupt handlers.

For protected mode programs, special entries must be made in the build file to modify the interrupt vector.

Ada source:

```
with System;
package P is

    task Normal_Interrupt_Handler is
        entry E;
        for E use at (segment => 0, offset => 20);
    end;

end P;

package body P is

    task body Normal_Interrupt_Handler is
    begin
        accept E do
            null;
        end E;
    end;

end P;
```

Build File (partial):

```
gate
D1HWIN?NMHandler          (interrupt,dpl=0),
D1HWIN?SingleStepInt      (interrupt,dpl=0),
D1HWIN?Breakpoint         (interrupt,dpl=0),
D1HWIN?InvalidOpcode      (interrupt,dpl=0),
D1HWIN?DevNotAvailable    (interrupt,dpl=0),
D1HWIN?DoubleFault        (interrupt,dpl=0),
D1HWIN?SegOverRun         (interrupt,dpl=0),
D1HWIN?InvalidTSS         (interrupt,dpl=0),
D1HWIN?SegmentFault       (interrupt,dpl=0),
D1HWIN?StackFault         (interrupt,dpl=0),
D1HWIN?ProtFault          (interrupt,dpl=0),
D1TINT?TimerInterrupt     (interrupt,dpl=0),
D1IPUT?Transmit           (interrupt,dpl=0),
D1IGET?Receive            (interrupt,dpl=0),
R1EHNE?RaiseNumericError  (interrupt,dpl=0),
R1EHCE?RaiseConstraintError (interrupt,dpl=0),
---> _AIH_00020           (interrupt,dpl=0);
```

User's Guide Implementation-Dependent Characteristics

```
table
  IDT(
    entry = (0:  R1EHNE?RaiseNumericError,      -- Vector Id
             1:  D1HWIN?SingleStepInt,          -- 0
             2:  D1HWIN?NMHandler,              -- 1
             3:  D1HWIN?Breakpoint,             -- 2
             4:  R1EHNE?RaiseNumericError,      -- 3
             5:  R1EHCE?RaiseConstraintError,   -- 4

            13:  D1HWIN?ProtFault,              --12
            16:  R1EHNE?RaiseNumericError,      --13
            ---> 20:  AIH 00020,                 --14
            80h: D1TINT?TimerInterrupt,         --15
            86h: D1IGET?Receive,                --16
            87h: D1IPUT?Transmit));             --17
    end
```

Compilation, Linking, and Building:

```
$ ada Example_3
$ ada/link/tasks/interrupt_entry_Table=(20,20) Example_3
$ bld386/build=Example.BLD Example_3.OBJ
```

F.6.7.4 Example 4

This example shows how an End-Of-Interrupt message may be sent to the interrupting device.

Ada source:

```
with System;
package P is

  task Normal_Interrupt_Handler is
    entry E;
    for E use at (segment => 0, offset => 7);
  end;

end P;

with Machine_Code; use Machine_Code;
package body P is
```

User's Guide Implementation-Dependent Characteristics

```
procedure Send_EOI is
begin
  machine_instruction'
    (register_immediate, m_MOV, AL, 16#66#);
  machine_instruction'
    (immediate_register, m_OUT, 16#0e0#, AL);
end;
pragma inline (Send_EOI);

task body Normal_Interrupt_Handler is
begin
  accept E do
    <user code>
    Send_EOI;
  end E;
end;

end P;
```

Compilation and Linking:

```
$ ada Example_4
$ ada/link/tasks/interrupt_entry_table=(7,7) Example_4
```

F.6.8 Interrupt Queuing

DDC-I provides a useful feature that allows task entry calls made by interrupt handlers (fast and normal variant) to be queued if the called task is not waiting to accept the call, enabling the interrupt handler to complete to the IRET. What may not be clear is that the same interrupt may be queued only once at any given time in DDC-I's implementation. We have made this choice for two reasons:

- a) Queuing does not come for free, and queuing an interrupt more than once is considerably more expensive than queuing just one. DDC-I feels that most customers prefer their interrupt handlers to be as fast as possible and that we have chosen an implementation that balances performance with functionality.
- b) In most applications, if the servicing of an interrupt is not performed in a relatively short period of time, there is an unacceptable and potentially dangerous situation. Queuing the same interrupt more than once represents this situation.

User's Guide Implementation-Dependent Characteristics

Note that this note refers to queuing of the same interrupt more than once at the same time. Different interrupts may be queued at the same time as well as the same interrupt may be queued in a sequential manner as long as there is never a situation where the queuing overlaps in time.

If it is acceptable for your application to queue the same interrupt more than once, it is a relatively simple procedure to implement the mechanism yourself. Simply implement a high priority agent task that is called from the interrupt handler. The agent task accepts calls from the interrupt task and makes the call on behalf of the interrupt handler to the originally called task. By careful design, the agent task can be made to accept all calls from the interrupt task when they are made, but at the very least, must guarantee that at most one will be queued at a time.

F.6.9 Recurrence of Interrupts

DDC-I recommends the following techniques to ensure that an interrupt is completely handled before the same interrupt recurs. There are two cases to consider, i.e. the case of fast interrupt handlers and the case of normal interrupt handlers.

F.6.9.1 Fast Interrupt Handler

If the fast interrupt handler makes an entry call to a normal task, then place the code that reenables the interrupt at the end of the accept body of the called task. When this is done, the interrupt will not be reenabled before the rendezvous is actually completed between the fast interrupt handler and the called task even if the call was queued. Note that the interrupt task executes all the way through the IRET before the rendezvous is completed if the entry call was queued.

Normally, end-of-interrupt code using Low_Level_IO will be present in the accept body of the fast interrupt handler. This implies that the end-of-interrupt code will be executed before the rendezvous is completed, possibly allowing the interrupt to come in again before the application is ready to handle it.

If the fast interrupt handler does not make an entry call to another task, then placing the end-of-interrupt code in the accept body of the fast interrupt task will guarantee that the interrupt is completely serviced before another interrupt happens.

User's Guide Implementation-Dependent Characteristics

F.6.9.2 Normal Interrupt Handler

Place the code that reenables the interrupt at the end of the accept body of the normal interrupt task. When this is done, the interrupt will not be reenabled before the rendezvous is actually completed between the normal interrupt handler and the called task even if the call was queued. Even though the interrupt "completes" in the sense that the IRET is executed, the interrupt is not yet reenabled because the rendezvous with the normal task's interrupt entry has not been made.

If these techniques are used for either variant of interrupt handlers, caution must be taken that other tasks do not call the task entry which reenables interrupts if this can cause adverse side effects.

F.7 Unchecked Conversion

Unchecked conversion is only allowed between objects of the same "size". However, if scalar type has different sizes (packed and unpacked), unchecked conversion between such a type and another type is accepted if either the packed or the unpacked size fits the other type.

F.8 Input/Output Packages

In many embedded systems, there is no need for a traditional I/O system, but in order to support testing and validation, DDC-I has developed a small terminal oriented I/O system. This I/O system consists essentially of TEXT_IO adapted with respect to handling only a terminal and not file I/O (file I/O will cause a USE error to be raised) and a low level package called TERMINAL_DRIVER. A BASIC_IO package has been provided for convenience purposes, forming an interface between TEXT_IO and TERMINAL_DRIVER as illustrated in the following figure.

User's Guide Implementation-Dependent Characteristics

The `TERMINAL_DRIVER` package is the only package that is target dependent, i.e., it is the only package that need be changed when changing communications controllers. The actual body of the `TERMINAL_DRIVER` is written in assembly language, but an Ada interface to this body is provided. A user can also call the terminal driver routines directly, i.e. from an assembly language routine. `TEXT_IO` and `BASIC_IO` are written completely in Ada and need not be changed.

`BASIC_IO` provides a mapping between `TEXT_IO` control characters and ASCII as follows:

TEXT_IO	ASCII Character
LINE_TERMINATOR	ASCII.CR
PAGE_TERMINATOR	ASCII.FF
FILE_TERMINATOR	ASCII.EM (CTRL/Z)
NEW_LINE	ASCII.LF

The services provided by the terminal driver are:

- 1) Reading a character from the communications port.
- 2) Writing a character to the communications port.

User's Guide
Implementation-Dependent Characteristics

F.8.1 Package TEXT_IO

The specification of package TEXT_IO:

```
pragma page;
with BASIC_IO;

with IO_EXCEPTIONS;
package TEXT_IO is

    type FILE_TYPE is limited private;

    type FILE_MODE is (IN_FILE, OUT_FILE);

    type COUNT is range 0 .. INTEGER'LAST;
    subtype POSITIVE_COUNT is COUNT range 1 .. COUNT'LAST;
    UNBOUNDED: constant COUNT:= 0; -- line and page length

    -- max. size of an integer output field 2#....#
    subtype FIELD is INTEGER range 0 .. 35;

    subtype NUMBER_BASE is INTEGER range 2 .. 16;

    type TYPE_SET is (LOWER_CASE, UPPER_CASE);

pragma PAGE;
    -- File Management

    procedure CREATE (FILE : in out FILE_TYPE;
                     MODE : in FILE_MODE :=OUT_FILE;

User's Guide
Implementation-Dependent Characteristics

F.9 Machine Code Insertions

The reader should be familiar with the code generation strategy and the 80x86 instruction set to fully benefit from this section.

As described in chapter 13.8 of the ARM [DoD 83] it is possible to write procedures containing only code statements using the predefined package MACHINE_CODE. The package MACHINE_CODE defines the type MACHINE_INSTRUCTION which, used as a record aggregate, defines a machine code insertion. The following sections list the type MACHINE_INSTRUCTION and types on which it depends, give the restrictions, and show an example of how to use the package MACHINE_CODE.

F.9.1 Predefined Types for Machine Code Insertions

The following types are defined for use when making machine code insertions (their type declarations are given on the following pages):

```
type opcode_type
type operand_type
type register_type
type segment_register
type machine_instruction
```

The type REGISTER_TYPE defines registers. The registers STi describe registers on the floating stack. (ST is the top of the floating stack).

The type MACHINE_INSTRUCTION is a discriminant record type with which every kind of instruction can be described. Symbolic names may be used in the form

name' ADDRESS

Restrictions as to symbolic names can be found in section F.9.2. It should be mentioned that addresses are specified as 80386 addresses. In case of other targets, the scale factor should be set to "scale_1".

User's Guide Implementation-Dependent Characteristics

F.9.2 Restrictions

Only procedures, and not functions, may contain machine code insertions.

Symbolic names in the form `x'ADDRESS` can only be used in the following cases:

- 1) `x` is an object of scalar type or access type declared as an object, a formal parameter, or by static renaming.
- 2) `x` is an array with static constraints declared as an object (not as a formal parameter or by renaming).
- 3) `x` is a record declared as an object (not a formal parameter or by renaming).

The `m_CALL` can be used with "name" to call (for) a routine.

Two opcodes to handle labels have been defined:

- `m_label`: defines a label. The label number must be in the range $1 \leq x \leq 25$ and is put in the offset field in the first operand of the `MACHINE_INSTRUCTION`.
- `m_reset`: used to enable use of more than 25 labels. The label number after a `m_RESET` must be in the range $1 \leq x \leq 25$. To avoid errors you must make sure that all used labels have been defined before a reset, since the reset operation clears all used labels.

All floating instructions have at most one operand which can be any of the following:

- a memory address
- a register or an immediate value
- an entry in the floating stack

User's Guide Implementation-Dependent Characteristics

F.9.3 Examples

The following section contains examples of how to use the machine code insertions and lists the generated code.

F.9.4 Example Using Labels

The following assembler code can be described by machine code insertions as shown:

```
MOV AX,7
MOV CX,4
CMP AX,CX
JG 1
JE 2
MOV CX,AX
1: ADD AX,CX
2: MOV SS:[BP+DI], AX
```

package example_MC is

```
    procedure test_labels;
    pragma inline (test_labels);
```

end example_MC;

```
with MACHINE_CODE; use MACHINE_CODE;
package body example_MC is
```

procedure test_labels is

begin

```
        MACHINE_INSTRUCTION'(register_immediate, m_MOV, AX, 7);
        MACHINE_INSTRUCTION'(register_immediate, m_MOV, CX, 4);
        MACHINE_INSTRUCTION'(register_register, m_CMP, AX, CX);
        MACHINE_INSTRUCTION'(immediate, m_JG, 1);
        MACHINE_INSTRUCTION'(immediate, m_JE, 2);
        MACHINE_INSTRUCTION'(register_register, m_MOV, CX, AX);
        MACHINE_INSTRUCTION'(immediate, m_label, 1);
        MACHINE_INSTRUCTION'(register_register, m_ADD, AX, CX);
        MACHINE_INSTRUCTION'(immediate, m_label, 2);
        MACHINE_INSTRUCTION'(address_register, m_MOV, SS, BP,
        DI, scale_1, 0, AX);
```

end test_labels;

end example_MC;

User's Guide Implementation-Dependent Characteristics

F.9.5 Advanced Topics

This section describes some of the more intricate details of the workings of the machine code insertion facility. Special attention is paid to the way the Ada objects are referenced in the machine code body, and various alternatives are shown.

F.9.5.1 Address Specifications

Package `MACHINE_CODE` provides two alternative ways of specifying an address for an instruction. The first way is referred to as `SYSTEM_ADDRESS` and the parameter associated with this one must be specified via `OBJECT'ADDRESS` in the actual `MACHINE_CODE` insertion. The second way closely relates to the addressing which the 80x86 machines employ: an address has the general form

segment:[base+index*scale+offset]

The `ADDRESS` type expects the machine insertion to contain values for ALL these fields. The default value `NIL` for segment, base, and index may be selected (however, if base is `NIL`, so should index be). Scale **MUST** always be specified as `scale_1`, `scale_2`, `scale_4`, or `scale_8`. For 16 bit targets, `scale_1` is the only legal scale choice. The offset value must be in the range of -32768 .. 32767.

F.9.5.2 Referencing Procedure Parameters

The parameters of the procedure that consists of machine code insertions may be referenced by the machine insertions using the `SYSTEM_ADDRESS` or `ADDRESS` formats explained above. However, there is a great difference in the way in which they may be specified; whether the procedure is specified as `INLINE` or not.

`INLINE` machine insertions can deal with the parameters (and other visible variables) using the `SYSTEM_ADDRESS` form. This will be dealt with correctly even if the actual values are constants. Using the `ADDRESS` form in this context will be the user's responsibility since the user obviously attempts to address using register values obtained via other machine insertions. It is in general not possible to load the address of a parameter because an 'address' is a two component structure (selector and offset), and the only instruction to load an immediate address is the `LEA`, which will only give the offset. If coding requires access to addresses like this, one cannot `INLINE` expand the machine insertions. Care should be taken with references to objects outside the current block since the code generator in order to calculate

User's Guide Implementation-Dependent Characteristics

the proper frame value (using the display in each frame) will apply extra registers. The parameter addresses will, however, be calculated at the entry to the `INLINE` expanded routine to minimize this problem. `INLINE` expanded routines should NOT employ any `RET` instructions.

Pure procedure machine insertions need to know the layout of the parameters presented to, in this case, the called procedure. In particular, careful knowledge about the way parameters are passed is required to achieve a successful machine procedure. Again there are two alternatives:

The first assumes that the user takes over the responsibility for parameter addressing. With this method, the `SYSTEM_ADDRESS` format does not make sense (since it expects a procedural setup that is not set up in a machine procedure). The user must code the exit from the procedure and is also responsible for taking off parameters if so is required. The rules of Ada procedure calls must be followed. The calling conventions are summarized below.

The second alternative assumes that a specific abstract A-code insertion is present in the beginning and end of the machine procedure. Abstract A-code insertions are not generally available to an Ada user since they require extensive knowledge about the compiler intermediate text called abstract A-code. Thus, they will not be explained further here except for the below use.

These insertions enable the user to setup the procedural frame as expected by Ada and then allow the form `SYSTEM_ADDRESS` in accesses to parameters and variables. Again it is required to know the calling conventions to some extent; mainly to the extent that the access method for variables is clear. A record is, for example, transferred via its address, so access to record fields must first employ an `LES`-instruction and then use `ADDRESS` form using the read registers.

The insertions to apply in the beginning are:

```
pragma abstract_acode_insertions(true);
aa_instr'(aa_Create_Block,x,y,0,0,0);
aa_instr'(aa_End_of_declpart,0,0,0,0,0);
pragma abstract_acode_insertions(false);
```

and at the end:

```
pragma abstract_acode_insertions(true);
aa_instr'(aa_Exit_subprgrm,x,0,x,nil_arg,nil_arg); -- (1)
aa_instr'(aa_Set_block_level,y-1,0,0,0,0);
pragma abstract_acode_insertions(false);
```

User's Guide Implementation-Dependent Characteristics

where the `x` value represents the number of words taken by the parameters, and `y` is the lexical block level of the machine procedure. However, if the procedure should leave the parameters on the stack (scalar IN OUT or OUT parameters), then the `Exit_subprgrm` insertion should read:

```
aa_instr'(aa_Exit_subprgrm,0,0,0,nil_arg,nil_arg); -- (2)
```

In this case, the caller moves the updated scalar values from the stack to their destinations after the call.

The `NIL_ARG` should be defined as :

```
nil_arg : constant := -32768;
```

WARNING: When using the `AA_INSTR` insertions, great care must be taken to assure that the `x` and `y` values are specified correctly. Failure to do this may lead to unpredictable crashes in compiler pass8.

F.9.5.3 Parameter Transfer

It may be a problem to figure out the correct number of words which the parameters take up on the stack (the `x` value). The following is a short description of the transfer method:

INTEGER types take up at least 1 storage unit. 32 bit integer types take up 2 words, and 64 bit integer types take up 4 words. In 32 bit targets, 16 bit integer types take up 2 words the low word being the value and the high word being an alignment word. **TASKS** are transferred as **INTEGER**.

ENUMERATION types take up as 16 bit **INTEGER** types (see above).

FLOAT types take up 2 words for 32 bit floats and 4 words for 64 bit floats.

ACCESS types are considered scalar values and consist of a 16 bit segment value and a 16 or 32 bit offset value. When 32 bit offset value, the segment value takes up 2 words the high word being the alignment word. The offset word(s) are the lowest, and the segment word(s) are the highest.

RECORD types are always transferred by address. A record is never a scalar value (so no post-procedure action is carried out when the record parameter is OUT or IN OUT). The representation is as for **ACCESS** types.

User's Guide Implementation-Dependent Characteristics

ARRAY values are transferred as one or two **ACCESS** values. If the array is constrained, only the array data address is transferred in the same manner as an **ACCESS** value. If the array is unconstrained below, the data address will be pushed by the address of the constraint. In this case, the two **ACCESS** values will NOT have any alignment words in 32 bit targets.

Packed ARRAY values (e.g. **STRING** types) are transferred as **ARRAY** values with the addition of an **INTEGER** bit offset as the highest word(s):

```
+H: BIT_OFFSET
+L: DATA_ADDRESS
+O: CONSTRAINT_ADDRESS      -- may be missing
```

The values **L** and **H** depend on the presence/absence of the constraint address and the sizes of constraint and data addresses.

In the two latter cases, the form parameter 'address' will always yield the address of the data. If access is required to constraint or bit offset, the instructions must use the **ADDRESS** form.

F.9.5.4 Example

A small example is shown below (16 bit target):

```
procedure unsigned_add
  (op1   : in      integer;
   op2   : in      integer;
   res   : out integer);
```

Notice that machine subprograms cannot be functions.

The parameters take up:

```
op1      : integer           : 1 word
op2      : integer           : 1 word
res      : integer           : 1 word
Total    :                   : 3 words
```

The body of the procedure might then be the following assuming that the procedure is defined at outermost package level:

```
procedure unsigned_add
  (op1   : in      integer;
   op2   : in      integer;
   res   : out integer) is
begin
```

User's Guide Implementation-Dependent Characteristics

```

pragma abstract_acode_insertions(true);
  aa_instr'(aa_Create_Block,3,1,0,0,0);  -- x = 3, y = 1
  aa_instr'(aa_End_of_declpart,0,0,0,0,0);
pragma abstract_acode_insertions(false);

machine_instruction'(register_system_address, m_MOV,
                     AX, op1'address);
machine_instruction'(register_system_address, m_ADD,
                     AX, op2'address);
machine_instruction'(immediate, m_JNC, 1);
machine_instruction'(immediate, m_INT, 5);
machine_instruction'(immediate, m_label, 1);
machine_instruction'(system_address_register, m_MOV,
                     res'address, AX);

pragma abstract_acode_insertions(true);
  aa_instr'(aa_Exit_subprgm,0,0,0,nil_arg,nil_arg);-- (2)
  aa_instr'(aa_Set_block_level,0,0,0,0,0);  -- y-1 = 0
pragma abstract_acode_insertions(false);
end unsigned_add;

```

A routine of this complexity is a candidate for `INLINE` expansion. In this case, no changes to the above 'machine_instruction' statements are required. Please notice that there is a difference between addressing record fields when the routine is `INLINE` and when it is not:

```

type rec is
  record
    low      : integer;
    high     : integer;
  end record;

procedure add_32 is
  (op1      : in      integer;
   op2      : in      integer;
   res      : out rec);

```

The parameters take up $1 + 1 + 2$ words = 4 words. The RES parameter will be addressed directly when `INLINE` expanded, i.e. it is possible to write:

```

machine_instruction'(system_address_register, m_MOV,
                     res'address, AX);

```

This would, in the not `INLINED` version, be the same as updating that place on the stack where the address of RES is placed. In this case, the insertion must read:

```

machine_instruction'(register_system_address, m_LES,
                     SI, res'address);
  -- LES SI,[BP+...]
machine_instruction'(address_register, m_MOV,

```

User's Guide Implementation-Dependent Characteristics

```
ES, SI, nil, scale_1, 0, AX);  
-- MOV ES:[SI+0],AX
```

As may be seen, great care must be taken to ensure correct machine code insertions. A help could be to first write the routine in Ada, then disassemble to see the involved addressings, and finally write the machine procedure using the collected knowledge.

Please notice that `INLINED` machine insertions also generate code for the procedure itself. This code will be removed when the `/NOCHECK` qualifier is applied to the compilation. Also not `INLINED` procedures using the `AA_INSTR` insertion, which is explained above, will automatically get a `storage_check` call (as do all Ada subprograms). On top of that, 8 bytes are set aside in the created frame, which may freely be used by the routine as temporary space. The 8 bytes are located just below the display vector of the frame (from `SP` and up). The `storage_check` call will not be generated when the compiler is invoked with `/NOCHECK`.

The user also has the option `NOT` to create any blocks at all, but then he should be certain that the return from the routine is made in the proper way (use the `RETP` instruction (return and pop) or the `RET`). Again it will help first to do an Ada version and see what the compiler expects to be done.

F.10 Package Tasktypes

The TaskTypes packages defines the TaskControlBlock type. This data structure could be useful in debugging a tasking program. The following package Tasktypes is for all DACS-80x86 Real Address Mode compilers, except for DACS-80386PM.

with System;

package TaskTypes is

```
subtype Offset      is System.UnsignedWord;
subtype BlockId     is System.UnsignedWord;
```

```
type TaskEntry      is new System.UnsignedWord;
type EntryIndex     is new System.UnsignedWord;
type AlternativeId   is new System.UnsignedWord;
type Ticks          is new System.DWord;
type Bool           is new Boolean;
for Bool'size       use 8;
type UIntg          is new System.UnsignedWord;
```

```
type TaskState is (Initial,
  -- The task is created, but activation
  -- has not started yet.

  Engaged,
  -- The task has called an entry, and the
  -- call is now accepted, ie. the rendezvous
  -- is in progress.

  Running,
  -- Covers all other states.

  Delayed,
  -- The task awaits a timeout to expire.

  EntryCallingTimed,
  -- The task has called an entry which
  -- is not yet accepted.

  EntryCallingUnconditional,
  -- The task has called an entry
  -- unconditionally,
  -- which is not yet accepted.

  SelectingTimed,
  -- The task is waiting in a select statement
  -- with an open delay alternative.

  SelectingUnconditional,
  -- The task waits in a select statement
  -- entirely with accept statements.
```

User's Guide Implementation-Dependent Characteristics

SelectingTerminable,
-- The task waits in a select statement
-- with an open terminate alternative.

Accepting,
-- The task waits in an accept statement.

Synchronizing,
-- The task waits in an accept statement
-- with no statement list.

Completed,
-- The task has completed the execution of
-- its statement list, but not all dependent
-- tasks are terminated.

Terminated);
-- The task and all its descendants
-- are terminated.

```
for TaskState use (Initial => 16#00# ,  
Engaged => 16#08# ,  
Running => 16#10# ,  
Delayed => 16#18# ,  
EntryCallingTimed => 16#20# ,  
EntryCallingUnconditional => 16#28# ,  
SelectingTimed => 16#31# ,  
SelectingUnconditional => 16#39# ,  
SelectingTerminable => 16#41# ,  
Accepting => 16#4A# ,  
Synchronizing => 16#53# ,  
Completed => 16#5C# ,  
Terminated => 16#54#);
```

```
for TaskState'size use 8;
```

```
type TaskTypeDescriptor is  
record  
    priority           : System.Priority;  
    entry_count        : UIntg;  
    block_id          : BlockId;  
    first_own_address  : System.Address;  
    module_number      : UIntg;  
    entry_number       : UIntg;  
    code_address       : System.Address;  
    stack_size         : System.DWord;  
    dummy              : Integer;  
    stack_segment_size : UIntg;  
end record;
```

```
type AccTaskTypeDescriptor is access TaskTypeDescriptor;
```

```
type NPXSaveArea is array(1..48) of System.UnsignedWord;
```

User's Guide
Implementation-Dependent Characteristics

```
type FlagsType is
  record
    NPXFlag      : Bool;
    InterruptFlag : Bool;
  end record;
pragma pack(FlagsType);

type StatesType is
  record
    state      : TaskState;
    is_abnormal : Bool;
    is_activated : Bool;
    failure     : Bool;
  end record;
pragma pack(StatesType);

TBlockingTask : System.TaskValue;  -- Only used in HDS
PBlockingTask : System.TaskValue;  -- Only used in HDS
collection    : System.Address;
partition     : Integer;

-- NPX save area
--
-- When the application is linked with /NPX, a special
-- save area for the NPX is allocated at the very end
-- of every TCB.
-- ie:
--
--   case NPX_Present is
--     when TRUE  => NPXsave    : NPXSaveArea;
--     when FALSE => null;
--   end case;

end record;

-- The following is to assure that the TCB has the expected size:

TCB_size      : constant INTEGER := TaskControlBlock'size / 8;

-- subtype TCB_ok_value is INTEGER range 214 .. 214;
-- TCB_ok      : constant TCB_ok_value := TaskControlBlock'size / 8;

end TaskTypes;

For DACS-80386PM package TaskTypes is as above except for the below
declarations:

subtype Offset    is System.UnsignedDWord;
subtype BlockId   is System.UnsignedDWord;

type TaskEntry    is new System.UnsignedDWord;
type EntryIndex   is new System.UnsignedDWord;
type AlternativeId is new System.UnsignedDWord;
type Ticks        is new System.UnsignedDWord;
type UIntg        is new System.UnsignedDWord;

type NPXSaveArea is array(1..54) of System.UnsignedWord;
```
