Certificate Information

The following Ada implementation was tested and determined to pass ACVC 1.11. Testing was completed on 901214.

Compiler Name and Version: XD Ada MIL-STD-1750A Version 1.2

Host Computer System: Local Area VAX Cluster (comprising a VAXserver 3600, 2
MicroVAX 2000's and 1 MicroVAX II) (under VMS 5.3)

Target Computer System: Fairchild F9450 on a SBC-50 board (MIL-STD-1750A) (bare
machine)

A more detailed description of this Ada implementation is found in section 3.1 of this report. As a result of this validation effort, Validation Certificate #901214N1.11080 is awarded to SD-Scicon UK Ltd. This certificate expires on 01 JUNE 1992.

This report has been reviewed and is approved.

DECLARATION OF CONFORMANCE

The following declaration of conformance was supplied by the customer.

DECLARATION OF CONFORMANCE

Customer: SD-Scicon UK Limited

Ada Validation Facility: The National Computing Centre Limited
Oxford Road
Manchester
M1 7ED
United Kingdom

ACVC Version: 1.11

Ada Implementation:

Ada Compiler Name: XD Ada MIL-STD-1750A

Version: 2.2

Host Computer System: Local Area VAX Cluster (comprising a VAXserver 3600, 2 MicroVAX 200's and 1 MicroVAX II) (under VMS 5.3)

Target Computer System: Fairchild F9450 on a SBC-50 board (MIL-STD-1750A) (bare machine)

Customer's Declaration

I, the undersigned, representing SD-Scicon UK Limited, declare that SD-Scicon UK Limited has no knowledge of deliberate deviations from the Ada Language Standard ANSI/MIL-STD-1815A in the implementation(s) listed in this declaration.

CHAPTER 1

INTRODUCTION

The Ada implementation described above was tested according to the Ada Validation Procedures [Pro90] against the Ada Standard [Ada83] using the current Ada Compiler Validation Capability (ACVC). This Validation Summary Report (VSR) gives an account of the testing of this Ada implementation. For any technical terms used in this report, the reader is referred to [Pro90]. A detailed description of the ACVC may be found in the current ACVC User's Guide [UG89].

1.1 USE OF THIS VALIDATION SUMMARY REPORT

Consistent with the national laws of the originating country, the Ada Certification Body may make full and free public disclosure of this report. In the United States, this is provided in accordance with the "Freedom of Information Act" (5 U.S.C. #552). The results of this validation apply only to the computers, operating systems, and compiler versions identified in this report.

The organizations represented on the signature page of this report do not represent or warrant that all statements set forth in this report are accurate and complete, or that the subject implementation has no nonconformities to the Ada Standard other than those presented. Copies of this report are available to the public from the AVF which performed this validation or from:

National Technical Information Service
5285 Port Royal Road
Springfield
VA 22161

Questions regarding this report or the validation test results should be directed to the AVF which performed this validation or to:

Ada Validation Organization
Institute for Defense Analyses
1801 North Beauregard Street
Alexandria
VA 22311

1.3 ACVC TEST CLASSES

Compliance of Ada implementations is tested by means of the ACVC. The ACVC contains a collection of test programs structured into six test classes: A, B, C, D, E, and L. The first letter of a test name identifies the class to which it belongs. Class A, C, D, and E tests are executable. Class B and class L tests are expected to produce errors at compile time and link time, respectively.

The executable tests are written in a self-checking manner and produce a PASSED, FAILED, or NOT APPLICABLE message indicating the result when they are executed. Three Ada library units, the packages REPORT and SPPRT13, and the procedure CHECK_FILE are used for this purpose. The package REPORT also provides a set of identity functions used to defeat some compiler optimizations allowed by the Ada Standard that would circumvent a test objective. The package SPPRT13 is used by many tests for Chapter 13 of the Ada Standard. The procedure CHECK_FILE is used to check the contents of text files written by some of the Class C tests for Chapter 14 of the Ada Standard. The operation of REPORT and CHECK_FILE is checked by a set of executable tests. If these units are not operating correctly, validation testing is discontinued.

Class B tests check that a compiler detects illegal language usage. Class B tests are not executable. Each test in this class is compiled and the resulting compilation listing is examined to verify that all violations of the Ada Standard are detected. Some of the class B tests contain legal Ada code which must not be flagged illegal by the compiler. This behaviour is also verified.

Class L tests check that an Ada implementation correctly detects violation of the Ada Standard involving multiple, separately compiled units. Errors are expected at link time, and execution is attempted.

In some tests of the ACVC, certain macro strings have to be replaced by implementation-specific values -- for example, the largest integer. A list of the values used for this implementation is provided in Appendix A. In addition to these anticipated test modifications, additional changes may be required to remove unforeseen conflicts between the tests and implementation-dependent characteristics. The modifications required for this implementation are described in section 2.3. For each Ada implementation, a customized test suite is produced by the AVF. This customization consists of making the modifications described in the preceding paragraph, removing withdrawn tests (see section 2.1) and, possibly some inapplicable tests (see Section 3.2 and [UG89]).

In order to pass an ACVC an Ada implementation must process each test of the customized test suite according to the Ada Standard.

1.4 DEFINITION OF TERMS

INTRODUCTION

Ada Compiler	The software and any needed hardware that have to be added to a given host and target computer system to allow transformation of Ada programs into executable form and execution thereof.
Ada Compiler Validation Capability (ACVC)	The means for testing compliance of Ada implementations, consisting of the test suite, the support programs, the ACVC user's guide and the template for the validation summary report.
Ada Implementation	An Ada compiler with its host computer system and its target computer system
Ada Validation Facility (AVF)	The part of the certification body which carries out the procedures required to establish the compliance of an Ada implementation.
Ada Validation Organization (AVO)	The part of the certification body that provides technical guidance for operations of the Ada Certification system.
Compliance of an Ada Implementation	The ability of the implementation to pass an ACVC version.
Computer System	A functional unit, consisting of one or more computers and associated software, that uses common storage for all or part of a program and also for all or part of the data necessary for the execution of the program; executes user-written or user-designated programs; performs user-designated data manipulation, including arithmetic operations and logic operations; and that can execute programs that modify themselves during execution. A computer system may be a stand-alone unit or may consist of several inter-connected units.
Conformity	Fulfilment by a product, process or service of all requirements specified.
Customer	An individual or corporate entity who enters into an agreement with an AVF which specifies the terms and conditions for AVF services (of any kind) to be performed.
Declaration of Conformance	A formal statement from a customer assuring that conformity is realized or attainable on the Ada implementation for which validation status is realized.
Host Computer System	A computer system where Ada source programs are transformed into executable form.
Inapplicable test	A test that contains one or more test objectives found to be irrelevant for the given Ada implementation.

INTRODUCTION

Operating System	Software that controls the execution of programs and that provides services such as resource allocation, scheduling, input/output control, and data management. Usually, operating systems are predominantly software, but partial or complete hardware implementations are possible.
Target Computer System	A computer system where the executable form of Ada programs are executed.
Validated Ada Compiler	The compiler of a validated Ada implementation.
Validated Ada Implementation	An Ada implementation that has been validated successfully either by AVF testing or by registration [Pro90].
Validation	The process of checking the conformity of an Ada compiler to the Ada programming language and of issuing a certificate for this implementation.
Withdrawn test	A test found to be incorrect and not used in conformity testing. A test may be incorrect because it has an invalid test objective, fails to meet its test objective, or contains erroneous or illegal use of the Ada programming language.

CHAPTER 2

IMPLEMENTATION DEPENDENCIES

2.1 WITHDRAWN TESTS

The following tests have been withdrawn by the AVO. The rationale for withdrawing each test is available from either the AVO or the AVF. The publication date for this list of withdrawn tests is 90-10-12.

CE3812A	CE3814A	CE3902B			

2.2 INAPPLICABLE TESTS

A test is inapplicable if it contains test objectives which are irrelevant for a given Ada implementation. The inapplicability criteria for some tests are explained in documents issued by ISO and the AJPO known as Ada Issues and commonly referenced in the format AI-dddd. For this implementation, the following tests were inapplicable for the reasons indicated; references to Ada Issues are included as appropriate.

The following 285 tests have floating-point type declarations requiring more digits than SYSTEM.MAX_DIGITS:

C24113F..Y (20 tests)	C35705F..Y (20 tests)
C35706F..Y (20 tests)	C35707F..Y (20 tests)
C35708F..Y (20 tests)	C35802F..Z (21 tests)
C45241F..Y (20 tests)	C45321F..Y (20 tests)
C45421F..Y (20 tests)	C45521F..Z (21 tests)
C45524F..Z (21 tests)	C45621F..Z (21 tests)
C45641F..Y (20 tests)	C46012F..Z (21 tests)

IMPLEMENTATION DEPENDENCIES

The following 21 tests check for the predefined type `SHORT_INTEGER`:

C35404B	B36105C	C45231B	C45304B	C45411B
C45412B	C45502B	C45503B	C45504B	C45504E
C45611B	C45613B	C45614B	C45631B	C45632B
B52004E	C55B07B	B55B09D	B86001V	C86006D
CD7101E				

C35404D, C45231D, B86001X, C86006E, and CD7101G check for a predefined integer type with a name other than `INTEGER`, `LONG_INTEGER`, or `SHORT_INTEGER`.

C35702A, C35713B, C45423B, B86001T, and C86006H check for the predefined type `SHORT_FLOAT`.

C35713D and B86001Z check for a predefined floating-point type with a name other than `FLOAT`, `LONG_FLOAT`, or `SHORT_FLOAT`.

C45423A, C45523A and C45622A check that if `MACHINE_OVERFLOW` is `TRUE` and the results of various floating-point operations lie outside the range of the base type, then the proper exception is raised; for this implementation, `MACHINE_OVERFLOW` is `FALSE`.

C45531M..P and C45532M..P (8 tests) check fixed-point operations for types that require a `SYSTEM.MAX_MANTISSA` of 47 or greater; for this implementation, `MAX_MANTISSA` is less than 47.

C86001F recompiles package `SYSTEM`, making package `TEXT_IO`, and hence package `REPORT`, obsolete. For this implementation, the package `TEXT_IO` is dependent upon package `SYSTEM`.

B86001Y checks for a predefined fixed-point type other than `DURATION`.

C96005B checks for values of type `DURATION`'`BASE` that are outside the range of `DURATION`. There are no such values for this implementation.

CD1009C uses a representation clause specifying a non-default size for a floating-point type.

CD2A84A, CD2A84E, CD2A84I..J (2 tests), and CD2A84O use representation clauses specifying non-default sizes for access types.

The following 263 tests check for sequential, text, and direct access files:

CE2102A..C (3)	CE2102G..H (2)	CE2102K	CE2102N..Y (12)
CE2103C..D (2)	CE2104A..D (4)	CE2105A..B (2)	CE2106A..B (2)
CE2107A..H (8)	CE2107L	CE2108A..H (8)	CE2109A..C (3)
CE2110A..D (4)	CE2111A..I (9)	CE2115A..B (2)	CE2120A..B (2)
CE2201A..C (3)	EE2201D..E (2)	CE2201F..N (9)	CE2203A
CE2204A..D (4)	CE2205A	CE2206A	CE2208B
CE2401A..C (3)	EE2401D	CE2401E..F (2)	EE2401G

IMPLEMENTATION DEPENDENCIES

CE3411C	CE3412A	EE3412C	CE3413A
CE3413C	CE3414A	CE3602A..D (4)	CE3603A
CE3604A..B (2)	CE3605A..E (5)	CE3606A..B (2)	CE3704A..F (6)
CE3704M..O (3)	CE3705A..E (5)	CE3706D	CE3706F..G (2)
CE3804A..P (16)	CE3805A..B (2)	CE3806A..B (2)	CE3806D..E (2)
CE3806H	CE3904A..B (2)	CE3905A..C (3)	CE3905L
CE3906A..C (3)	CE3906E..F (2)		

CE3413B checks operations on text files; this implementation does not support external files. (See section 2.3).

CE3806G assumes that implementations not supporting text files will raise `USE_ERROR` if `TEXT_IO.CREATE` is called; for this implementation `NAME_ERROR` is raised if a non-null file name is specified. (See section 2.3).

2.3 TEST MODIFICATIONS

Modifications (see section 1.3) were required for 14 tests.

The following test was split because syntax errors at one point resulted in the compiler not detecting other errors in the test:

B97301E

C45524A..E (5 tests) were graded passed by Test Modification as directed by the AVO. These tests expect that a repeated division will result in zero; but the Ada standard only requires that the result lie in the smallest safe interval. Thus, the tests were modified to check that the result was within the smallest safe interval by adding the following code after line 138; the modified tests were passed:

```
ELSIF VAL <= F'SAFE_SMALL THEN COMMENT ("UNDERFLOW IS GRADUAL");
```

C64103A and C95084A were graded passed by Evaluation Modification as directed by the AVO. Because this implementation's actual values for `LONG_FLOAT'SAFE_LARGE` and

IMPLEMENTATION DEPENDENCIES

SHORT_FLOAT'LAST lie within one (SHORT_FLOAT) model interval of each other, the tests' floating-point applicability check may evaluate to TRUE and yet the subsequent expected exception need not be raised. The AVO ruled that the implementation's behaviour should be graded passed because the implementation passed the integer and fixed-point checks. The following REPORT.FAILED messages were produced after the type conversions at line 198 in C64103A and lines 101 and 250 in C95084A failed to raise exceptions:

C64103A: "EXCEPTION NOT RAISED AFTER CALL -P2 (B)"

C95084A "EXCEPTION NOT RAISED BEFORE CALL - T2 (A)"
"EXCEPTION NOT RAISED AFTER CALL - T5 (B)"

C64201C, C99005A and A98002A were graded passed by Test Modification as directed by the AVO. These tests respectively contain 12, 12 and 17 tasks; given the implementation's default amount of storage allocated to a task, this number of tasks causes STORAGE_ERROR to be raised. These tests were modified to include length clauses that specified 1K bytes for the task storage size (for tests C99005A and A98002A, this required that the single tasks be re-written as task types); the modified tests were passed.

CE3413B was graded inapplicable by Evaluation Modification as directed by the AVO. This test includes the expression "COUNT'LAST > 150000", which raises CONSTRAINT_ERROR on the implicit conversion of the integer literal to type COUNT since COUNT'LAST = 32,767; there is no handler for this exception, so test execution is terminated. The AVO ruled that this behaviour was acceptable; the AVO ruled that the test be graded inapplicable because it checks certain file operations and this implementation does not support external files.

CE3806G was graded inapplicable by Evaluation Modification as directed by the AVO. This test is inapplicable to implementations that do not support external files. However, the test incorrectly continues execution after handling NAME_ERROR at line 42 (and calling REPORT.NOT_APPLICABLE), and the subsequent attempt to create a file results in the test aborting with an unhandled NAME_ERROR exception.

CE3901A was graded passed by Test Modification as directed by the AVO. This test expects that implementations that do not support external files will raise USE_ERROR on the attempt to create a file at line 52; this implementation raises NAME_ERROR, as allowed by AI-00332. The test was modified by inserting '| NAME_ERROR' into the exception choice at line 52, and the modified test was passed.

CHAPTER 3

PROCESSING INFORMATION

3.1 TESTING ENVIRONMENT

The host and target computers systems were connected via a standard RS232 link. Other details concerning the Ada implementation tested in this validation effort is described adequately by the information given in the initial pages of this report.

For a point of contact for technical informatic., about this Ada implementation system, see:

Tim Magness
SD-Scicon UK Ltd
Pembroke House
Pembroke Broadway
Camberley
Surrey
GU15 3XD

For a point of contact for sales information about this Ada implementation system, see:

Colin Foster
SD-Scicon UK Ltd
Pembroke House
Pembroke Broadway
Camberley
Surrey
GU15 3XD

Testing of this Ada implementation was conducted at the customer's site by a validation team from the AVF.

3.2 SUMMARY OF TEST RESULTS

An Ada Implementation passes a given ACVC version if it processes each test of the customized test suite in accordance with the Ada Programming Language Standard, whether the test is applicable or inapplicable; otherwise, the Ada Implementation fails the ACVC: [Pro90].

For all processed tests (inapplicable and applicable), a result was obtained that conforms to the Ada Programming Language Standard.

a)	Total Number of Applicable Tests	3486
----	----------------------------------	------

PROCESSING INFORMATION

b)	Total Number of Withdrawn Tests	81	
c)	Processed Inapplicable Tests	603	
d)	Non-Processed I/O Tests	0	
e)	Non-Processed Floating-Point Precision Tests	0	
f)	Total Number of Inapplicable Tests	603	(c+d+e)
g)	Total Number of Tests for ACVC 1.11	4170	(a+b+f)

When this compiler was tested, the tests listed in section 2.1 had been withdrawn because of test errors.

3.3 TEST EXECUTION

Version 1.11 of the ACVC comprises 4170 tests. When this compiler was tested, the tests listed in section 2.1 had been withdrawn because of test errors. The AVF determined that 603 tests were inapplicable to this implementation. All inapplicable tests were processed during validation testing. In addition, the modified tests mentioned in section 2.3 were also processed.

A **magnetic tape** containing the customized test suite (see section 1.3) was taken on-site by the validation team for processing. The contents of the **magnetic tape** were loaded onto a VAX 8600 and were transferred via DECnet to the host computer system.

After the test files were loaded onto the host computer, the full set of tests was processed by the Ada implementation.

The tests were compiled and linked on the host computer system, as appropriate. The executable images were transferred to the target computer system by the communications link described above, and run. The results were captured on the host computer system.

Testing was performed using command scripts provided by the customer and reviewed by the validation team. See Appendix B for a complete listing of the processing options for this implementation. It also indicates the default options. The options invoked explicitly for validation testing during this test were:

/LIST	used for tests requiring compilation listings
/DEV=DAY_0	in-house compiler option to remove extraneous listing information eg dates and headers.

Test output, compiler and linker listings, and job logs were captured on **magnetic tape** and archived at the AVF. The listings examined on-site by the validation team were also archived.

APPENDIX A

MACRO PARAMETERS

This appendix contains the macro parameters used for customizing the ACVC. The meaning and purpose of these parameters are explained in [UG89]. The parameter values are presented in two tables. The first table lists the values that are defined in terms of the maximum input-line length, which is the value for \$MAX_IN-LEN--also listed here. These values are expressed here as Ada string aggregates, where "V" represents the maximum input-line length.

<u>Macro Parameter</u>	<u>Macro Value</u>
\$MAX_IN_LEN	255
\$BIG_ID1	(1..V-1 => 'A', V => '1')

APPENDIX B

COMPILATION SYSTEM OPTIONS

The compiler options of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this appendix are to compiler documentation and not to this report.

XDADA

XDADA

Invokes the XD Ada compiler to compile one or more source files.

Format **XDADA** *file-spec[,...]*

Command Qualifiers

/LIBRARY = directory-spec

Defaults

/LIBRARY = XDADA\$LIB

Positional Qualifiers

/[NO]ANALYSIS_DATA [= file-spec]

Prompt

_File:

Command Parameters

file-spec

Specifies one or more XD Ada source files to be compiled. If you do not specify a file type, the compiler uses the default file type of .ADA. No wildcard characters are allowed in the file specifications.

XDADA

If you specify more than one input file, you must separate adjacent file specifications with a comma (.). You cannot use a plus sign (+) to separate file specifications.

Description

The XDADA command is one of four commands used to compile compilation units. The other three are the XDACS COMPILE, RECOMPILE and LOAD commands.

The XDADA command can be used at any time to compile one or more source files (.ADA). Source files are compiled in the order they appear on the command line. If a source file contains more than one compilation unit, they are compiled in the order they appear in the source file.

The XDADA command compiles units in the context of the current program library. Whenever a compilation unit is compiled without error, the current program library is updated with the object module and other products of the compilation.

Command Qualifiers

/LIBRARY = directory-spec

Specifies the program library that is to be the current program library for the duration of the compilation. The directory specified must be an already existing XD Ada program library. No wildcard characters are allowed in the directory specification.

By default, the current program library is the program library last specified in an XDACS SET LIBRARY command. The logical name XDADA\$LIB is assigned to the program library specified in an XDACS SET LIBRARY command.

Positional Qualifiers

/ANALYSIS_DATA[= file-spec]

/NOANALYSIS_DATA (D)

Controls whether a data analysis file containing source code cross-reference and static analysis information is created. The data analysis file is supported only for use with DIGITAL layered products, such as the VAX Source Code Analyzer.

XDADA

One data analysis file is created for each source file compiled. The default directory for data analysis files is the current default directory. The default file name is the name of the source file being compiled. The default file type is .ANA. No wildcard characters are allowed in the file specification.

By default, no data analysis file is created.

/CHECK

/NOCHECK

Controls whether all run-time checks are suppressed. The /NOCHECK qualifier is equivalent to having all possible SUPPRESS pragmas in the source code.

Explicit use of the /CHECK qualifier overrides any occurrences of the pragmas SUPPRESS and SUPPRESS_ALL in the source code, without the need to edit the source code.

By default, run-time checks are suppressed only in cases where a pragma SUPPRESS or SUPPRESS_ALL appears in the source.

See the *Reference Manual for the Ada Programming Language* for more information on the pragmas SUPPRESS and SUPPRESS_ALL.

/COPY_SOURCE (D)

/NOCOPY_SOURCE

Controls whether a copied source file (.ADC) is created in the current program library when a compilation unit is compiled without error. The RECOMPILE command (and thus the COMPILE command) requires that a copied source file exist in the current program library for any unit that is to be recompiled.

By default, a copied source file is created in the current program library when a unit is compiled without error.

/DEBUG[=(option[,...])] (D)

/NODEBUG

Controls which compiler debugging options are provided. You can debug XD Ada programs with the XD Ada Debugger. You can request the following options:

XDADA

ALL	Provides both SYMBOLS and TRACEBACK.
NONE	Provides neither SYMBOLS nor TRACEBACK.
[NO]SYMBOLS	Controls whether debugger symbol records are included in the object file.
[NO]TRACEBACK	Controls whether traceback information (a subset of the debugger symbol information) is included in the object file.

By default, both debugger symbol records and traceback information are included in the object file (/DEBUG = ALL, or equivalently: /DEBUG).

/DIAGNOSTICS[=file-spec]

/NODIAGNOSTICS (D)

Controls whether a diagnostics file containing compiler messages and diagnostic information is created. The diagnostics file is supported only for use with DIGITAL layered products, such as the VAX Language-Sensitive Editor.

One diagnostics file is created for each source file compiled. The default directory for diagnostics files is the current default directory. The default file name is the name of the source file being compiled. The default file type is .DIA. No wildcard characters are allowed in the file specification.

By default, no diagnostics file is created.

/ERROR_LIMIT[=n]

/NOERROR_LIMIT

Controls whether execution of the XDADA command for a given compilation unit is terminated upon the occurrence of the nth E-level error within that unit.

Error counts are not accumulated across a sequence of compilation units. If the /ERROR_LIMIT = n option is specified, each compilation unit may have up to n-1 errors without terminating the compilation. When the error limit is reached within a compilation unit, compilation of that unit is terminated, but compilation of subsequent units continues.

The /ERROR_LIMIT = 0 option is equivalent to ERROR_LIMIT = 1.

By default, execution of the XDADA command is terminated for a given compilation unit upon the occurrence of the 30th E-level error within that unit (equivalent to /ERROR_LIMIT = 30).

XDADA

/LIST[=file-spec]

/NOLIST (D)

Controls whether a listing file is created. One listing file is created for each source file compiled. The default directory for listing files is the current default directory. The default file name is the name of the source file being compiled. The default file type is .LIS. No wildcard characters are allowed in the file specification.

By default, the XDADA command does not create a listing file.

/LOAD[=option] (D)

/NOLOAD

Controls whether the current program library is updated with the successfully processed units contained in the specified source files. Depending on other qualifiers specified (or not specified) with the XDADA command, processing can involve full compilation, syntax checking only, and so on. The /NOLOAD qualifier causes the units in the specified source files to be processed, but prevents the current program library from being updated.

You can specify the following option:

[NO]REPLACE

Controls whether a unit added to the current program library replaces an existing unit with the same name. If you specify the NOREPLACE option, the unit is added to the current program library only if no existing unit has the same name, except if the new unit is the corresponding body of an existing specification or vice versa.

By default, the current program library is updated with the successfully processed units, and a unit added to the current program library replaces an existing unit with the same name.

/MACHINE_CODE[=option]

/NOMACHINE_CODE (D)

Controls whether generated machine code (approximating assembly language notation) is included in the listing file.

You can specify one of the following options:

SYMBOLIC:NONE	Provides machine code listing with no annotation.
SYMBOLIC:NORMAL	Provides machine code in the listing file; where possible, instructions are annotated with simple Ada names.
SYMBOLIC:MAXIMAL	Provides machine code in the listing file; where possible, instructions are annotated with Ada names, in expanded form if necessary.

The /MACHINE_CODE qualifier without options is equivalent to /MACHINE_CODE=SYMBOLIC:NORMAL.

By default, generated machine code is not included in the listing file.

/NOTE_SOURCE (D)

/NONOTE_SOURCE

Controls whether the file specification of the source file is noted in the program library when a unit is compiled without error. The COMPILER command uses this information to locate revised source files.

By default, the file specification of the source file is noted in the program library when a unit is compiled without error.

/OPTIMIZE[=(option[, ...])]

/NOOPTIMIZE

Controls the level of optimization that is applied in producing the compiled code. You can specify one of the following primary options:

TIME	Provides full optimization with time as the primary optimization criterion. Overrides any occurrences of the pragma OPTIMIZE(SPACE) in the source code.
SPACE	Provides full optimization with space as the primary optimization criterion. Overrides any occurrences of the pragma OPTIMIZE(TIME) in the source code.
DEVELOPMENT	Suggested when active development of a program is in progress. Provides some optimization, but development considerations and ease of debugging take preference over optimization. This option overrides pragmas that establish a dependence on a subprogram (the pragma INLINE), and thus reduces the need for recompilations when such bodies are modified.

XDADA

NONE

Provides no optimization. Suppresses expansions in line of subprograms, including those specified by the pragma `INLINE`.

The `/NOOPTIMIZE` qualifier is equivalent to `/OPTIMIZE = NONE`.

By default, the XDADA command applies full optimization with space as the primary optimization criterion (like `/OPTIMIZE = SPACE`, but observing uses of the pragma `OPTIMIZE`).

The `/OPTIMIZE` qualifier also has a set of secondary options that you can use separately or together with the primary options to override the default behavior for inline expansion and code motion.

The `INLINE` secondary option can have the following values:

`INLINE:NONE`

Disables subprogram expansion in line. This option overrides any occurrences of the pragma `INLINE` in the source code, without having to edit the source file. It also disables implicit expansion in line of subprograms. (*Implicit expansion in line* means that the compiler assumes a pragma `INLINE` for certain subprograms as an optimization.) A call to a subprogram in another unit is not expanded in line, regardless of the `/OPTIMIZE` options in effect when that unit was compiled.

`INLINE:NORMAL`

Provides normal subprogram expansion in line. Subprograms to which an explicit pragma `INLINE` applies are expanded in line under certain conditions. In addition, some subprograms are implicitly expanded in line. The compiler assumes a pragma `INLINE` for calls to some small local subprograms (subprograms that are declared in the same unit as the unit in which the call occurs).

`INLINE:SUBPROGRAMS`

Provides maximal subprogram expansion in line. In addition to the normal subprogram expansion in line that occurs when `INLINE:NORMAL` is specified, this option results in implicit expansion in line of some small subprograms declared in other units. The compiler assumes a pragma `INLINE` for any subprogram if it improves execution speed and reduces code size. This option may establish a dependence on the body of another unit, as would be the case if a pragma `INLINE` were specified explicitly in the source code.

INLINE:MAXIMAL	Provides maximal subprogram expansion in line. Maximal subprogram expansion in line occurs as for INLINE:SUBPROGRAMS.
INLINE:GENERIC	Provides normal subprogram inline expansion and maximal generic inline expansion. With this option, subprogram inline expansion occurs in the same manner as for INLINE:NORMAL. The compiler assumes a pragma INLINE_GENERIC for every instantiation in the unit being compiled unless a generic body is not available. This option may establish a dependence on the body of another unit, as would be the case if a pragma INLINE_GENERIC were specified explicitly in the source code.

The MOTION secondary option can have the following values:

MOTION:NONE	Disables code motion optimizations.
MOTION:LOOPS	Permits code motion optimization of loops. Where the compiler detects that a loop body contains invariant processing, it may generate code in which this processing is performed before entry to the loop instead of within the loop.
MOTION:MAXIMAL	Permits all code motion optimizations. In addition to the optimization of loops that occurs when MOTION:LOOPS is specified, this option permits analogous optimization of if and case statements: where the compiler detects that the branches of an if or case statement contain common processing, it may generate code in which this processing is performed before evaluation of the corresponding condition or case expression instead of within the branches.

By default, the /OPTIMIZE qualifier primary options have the following secondary-option values:

/OPTIMIZE=TIME	=(INLINE:NORMAL,MOTION:LOOPS)
/OPTIMIZE=SPACE	=(INLINE:NORMAL,MOTION:MAXIMAL)
/OPTIMIZE=DEVELOPMENT	=(INLINE:NONE,MOTION:NONE)
/OPTIMIZE=NONE	=(INLINE:NONE,MOTION:NONE)

/PREDEFINED_UNIT

/NOPREDEFINED_UNIT (D)

Controls the compilation of package \$RUN_TIME_SYSTEM, package \$TASKING_SYSTEM, and package MACHINE_CODE. You must specify this qualifier in order to be able to compile these packages. The

XDADA

qualifier is not required for the compilation of any other source files. See the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for more information.

By default, `/PREDEFINED_UNIT` is omitted.

`/SHOW[=option] (D)`

`/NOSHOW`

Controls the listing file options included when a listing file is provided. You can specify one of the following options:

ALL	Provides all listing file options.
[NO]PORTABILITY	Controls whether a program portability summary is included in the listing file. By default, the XDADA command provides a portability summary (<code>/SHOW=PORTABILITY</code>). See Appendix E for details of what can be included in a portability summary. See Chapter 5 of Version 2.0 of <i>Developing Ada Programs or VMS Systems</i> for more information on program portability.
NONE	Provides none of the listing file options (same as <code>/NOSHOW</code>).

By default, the XDADA command provides a portability summary (`/SHOW=PORTABILITY`).

`/SYNTAX_ONLY`

`/NOSYNTAX_ONLY (D)`

Controls whether the source file is to be checked only for correct syntax. If you specify the `/SYNTAX_ONLY` qualifier, other compiler checks are not performed (for example, semantic analysis, type checking, and so on).

In the presence of the `/LOAD=REPLACE` qualifier (the default), the `/SYNTAX_ONLY` qualifier updates the current program library with syntax-checked-only units. The units are considered to be obsolete and must be subsequently recompiled.

In the presence of the `/NOLOAD` qualifier, the `/SYNTAX_ONLY` qualifier checks the syntax of the specified units but does not update the library.

By default, the compiler performs all checks.

**/WARNINGS[= (message-option[,...])]
/NOWARNINGS**

Controls which categories of informational (I-level) and warning (W-level) messages are displayed and where those messages are displayed. You can specify any combination of the following message options:

WARNINGS: (*destination*[,...])
NOWARNINGS

WEAK_WARNINGS: (*destination*[,...])
NOWEAK_WARNINGS

SUPPLEMENTAL: (*destination*[,...])
NOSUPPLEMENTAL

COMPILATION_NOTES: (*destination*[,...])
NOCOMPILATION_NOTES

STATUS: (*destination*[,...])
NOSTATUS

The possible values of *destination* are ALL, NONE, or any combination of **TERMINAL** (terminal device), **LISTING** (listing file), **DIAGNOSTICS** (diagnostics file). The message categories are summarized as follows:

WARNINGS	W-level: Indicates a definite problem in a legal program, for example, an unknown pragma.
WEAK_WARNINGS	I-level: Indicates a potential problem in a legal program; for example, a possible CONSTRAINT_ERROR at run time. These are the only kind of I-level messages that are counted in the summary statistics at the end of a compilation.
SUPPLEMENTAL	I-level: Additional information associated with preceding E-level or W-level diagnostics.
COMPILATION_NOTES	I-level: Information about how the compiler translated a program, such as record layout, parameter-passing mechanisms, or decisions made for the pragmas INLINE , INTERFACE , or the import-subprogram pragmas.
STATUS	I-level: End of compilation statistics and other messages.

XDADA

The defaults are as follows.

```
/WARNINGS=(WARN:ALL,WEAK:ALL,SUPP:ALL,COMP:NONE,STAT:LIST)
```

Note that abbreviations are valid.

If you specify only some of the message categories with the /WARNINGS qualifier, the default values for other categories are used.

Examples

1. \$ XDADA MODEL_INTERFACE_,MODEL_INTERFACE,CONTROL_LOOP

The XDADA command compiles the compilation units contained in the three files MODEL_INTERFACE_.ADA, MODEL_INTERFACE.ADA, and CONTROL_LOOP.ADA, in the order given.

2. \$ XDADA/LIST/SHOW=ALL SCREEN_IO_,SCREEN_IO

The XDADA command compiles the compilation units contained in the two files SCREEN_IO_.ADA and SCREEN_IO.ADA, in the order given. The /LIST qualifier creates the listing files SCREEN_IO_.LIS and SCREEN_IO.LIS in the current default directory. The /SHOW=ALL qualifier causes all listing file options to be provided in the listing files.

LINKER OPTIONS

The linker options of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this appendix are to linker documentation and not to this report.

LINK

Creates an executable image file for the specified units. At Version 1.2, a new qualifier, /SELECTIVE, is supplied. The complete command specification is given for convenience.

Format **LINK** *unit-name[,...]* [*file-spec[,...]*]
 LINK/NOMAIN *unit-name[,...]* *file-spec[,...]*

LINK/NOMAIN only permissible with a single address state program.

Command Qualifiers	Defaults
/AFTER = time	/AFTER = TODAY
/BATCH_LOG = file-spec	See text.
/BRIEF	See text.
/COMMAND[= file-spec]	See text.
/[NO]DEBUG	/NODEBUG
/ELABORATION = file-spec	See text.
/FULL	See text.
/[NO]IMAGE[= file-spec]	/IMAGE
/[NO]KEEP	/KEEP
/[NO]LOG	/NOLOG
/[NO]MAIN	/MAIN

/[NO]SELECTIVE	/SELECTIVE
/SUBMIT	/WAIT
/WAIT	/WAIT
Parameter Qualifiers	Defaults
/LIBRARY	See text.
/MAPPING	See text.
/TARGET	See text.

LINK

Prompts

_Unit:

_File:

Command Parameters

unit-name

By default (or if you specify the /MAIN qualifier):

- You can specify up to 16 units (one per address state), the source code of which must be written in XD Ada.
- The parameter *unit-name* specifies an XD Ada main program, which must be a procedure with no parameters.

The /NOMAIN qualifier can only be used with a single address state program. If you specify the /NOMAIN qualifier:

- You can specify one or more foreign units that are to be included in the executable image. The unit names may include percent signs (%) and asterisks (*) as wildcard characters. (See the *VMS DCL Concepts Manual* for detailed information on wildcard characters.)
- The image transfer address comes from one of the foreign files specified.

file-spec

Specifies a list of object files, object libraries, mapping definition files, and target definition files, that are to be used in linking the program. The default directory is the current default directory. The default file type is .XOB, unless the /LIBRARY, /MAPPING, or /TARGET qualifier is used. No wildcard characters are allowed in a file specification.

If the file is an object library, you must use the /LIBRARY qualifier. The default file type is .XLB.

If the file is a mapping definition file, you must use the /MAPPING qualifier. The default file type is .MPD.

If the file is a target definition file you must use the /TARGET qualifier. The default file type is .TGD.

If you specify the /NOMAIN qualifier, the image transfer address comes from one of the files (not units) specified.

For a multiple program build, the list of foreign file specifications will be included in the build for each program in each address state.

Description

The LINK command performs the following steps:

1. Runs the prebuild phase to generate an elaboration list.
2. Checks if a pragma LINK_OPTION is specified for the main program, and if specified, verifies that the designated link option name is available in the current program library. If available, the copied link option files in the library corresponding to the link option are used, unless overridden by the /TARGET or /MAPPING qualifiers.

Note that, unlike the CHECK command, the pragma LINK_OPTION association for units other than the main program unit is not checked.

If no target link option is given for the main program unit or the designated target link option is not found in the library, and the logical name XDADA\$TARGET_DEF is not defined, and a /TARGET qualifier is not specified on the LINK command line, an error is issued. If no mapping link option is given for the main program unit or the designated mapping link option is not found in the library, and the logical name XDADA\$MAPPING_DEF is not defined, and a /MAPPING qualifier is not specified on the XDACS LINK command line, the default mapping in the target definition file is used.

3. If LINK/NOMAIN is not specified, checks that only one unit is specified and that it is an XD Ada main program.
4. Forms the closure of the main program (LINK/MAIN) or of the specified units (LINK/NOMAIN) and verifies that all units in the closure are present, current and complete. If XDACS detects an error, the operation is terminated at the end of the prebuild phase.
5. Creates a DCL command file for the builder. The command file is deleted after the LINK operation is completed or terminated, unless LINK/COMMAND is specified. If LINK/COMMAND is specified, the command file is retained for future use, and the build phase is not carried out.
6. Unless the /COMMAND qualifier is specified, performs the build phase as follows:
 - a. By default (LINK/WAIT), the command file generated in step 5 is executed in a subprocess. You must wait for the build operation to terminate before issuing another command. Note

LINK

that when you specify the /WAIT qualifier (the default), process logical names are propagated to the subprocess generated to execute the command file.

- b. If you specify the /SUBMIT qualifier, the builder command file is submitted as a batch job.
- 7. If the /DEBUG qualifier is included in the command line the debug symbol table information is placed in the .XXE file.
- 8. Creates a loadable output file with a default file type of .XXE.

XDACS output originating before the builder is invoked is reported to your terminal by default, or to a file specified with the /OUTPUT qualifier. Diagnostics are reported to your terminal, by default, or to a log file if the LINK command is executed in batch mode (XDACS LINK/SUBMIT).

See Chapter 7, Chapter 8, and Chapter 9 for more information on the XD Ada target-specific builder commands.

Command Qualifiers

/AFTER = time

Requests that the batch job be held until after a specific time, when the LINK command is executed in batch mode (LINK/SUBMIT). If the specified time has already passed, the job is queued for immediate processing.

You can specify either an absolute time or a combination of absolute and delta time. See the *VMS DCL Concepts Manual* (or type HELP Specify Date-Time at the DCL prompt) for complete information on specifying time values.

/BATCH_LOG = file-spec

Provides a file specification for the batch log file when the LINK command is executed in batch mode (LINK/SUBMIT).

If you do not give a directory specification with the *file-spec* option, the batch log file is created by default in the current default directory. If you do not give a file specification, the default file name is the job name specified with the /NAME=job-name qualifier. If no job name has been specified, the program library manager creates a file name comprising up to the first 39 characters of the first unit name specified. If you specified LINK/NOMAIN and no job name and there is a wildcard

LINK

character in the first unit specified, the program library manager uses the default file name XDACS_LINK. The default file type is .LOG.

/BRIEF

Directs the builder to produce a brief image map file. The /BRIEF qualifier is valid only if you also specify the /MAP qualifier with the LINK command. The /BRIEF qualifier is incompatible with the /FULL qualifier.

A brief image map file contains only the following sections:

- Object module information
- Segment mapping information
- Link run statistics

See also the description of the /FULL qualifier.

/COMMAND[=file-spec]

Controls whether the builder is invoked as a result of the LINK command, and determines whether the command file generated to invoke the builder is saved. If you specify the /COMMAND qualifier, XDACS does not invoke the builder, and the generated command file is saved for you to invoke or submit as a batch job.

The *file-spec* option allows you to enter a file specification for the generated command file. The default directory for the command file is the current default directory. By default, XDACS provides a file name comprising up to the first 39 characters of the first unit name specified. If you specified LINK/NOMAIN and you used a wildcard character in the first unit name specified, the program library manager uses the default file name XDACS_LINK. The default file type is .COM. No wildcard characters are allowed in the file specification.

By default, if the /COMMAND qualifier is not specified, XDACS deletes the generated command file when the LINK command completes normally or is terminated.

/DEBUG

/NODEBUG (D)

Controls whether a debugger symbol table is generated in the loadable image file.

By default, no debugger symbol table is created.

LINK

/ELABORATION = file-spec

Provides a file specification for the text file generated by the LINK command. The file is retained by XDACS only when the /COMMAND qualifier is used: that is, when the result of the LINK operation is to produce a builder command file for future use, rather than to invoke the builder immediately.

The generated text file contains the table that directs the elaboration of library packages in the closure of the units specified. Unless you also specify the /NOMAIN qualifier, the text file also contains the image transfer address.

The default directory for the generated text file is the current default directory. The default file type is .ELB. No wildcard characters are allowed in the file specification.

By default, if you do not specify the /ELABORATION qualifier, XDACS provides a file name comprising up to the first 39 characters of the first unit name specified.

By default, if you do not specify the /COMMAND qualifier, XDACS deletes the generated text file when the LINK command completes normally or is terminated.

/FULL

Directs the builder to produce a full image map file, which is the most complete image map. The /FULL qualifier is valid only if you also specify the /MAP qualifier with the LINK command. Also, the /FULL qualifier is incompatible with the /BRIEF qualifier.

A full image map file contains the following sections:

- Object module information
- Segment mapping information
- Symbol address information
- Exception numbers
- Link run statistics

/IMAGE[= file-spec] (D)

/NOIMAGE

Controls whether the LINK command creates a loadable image file and optionally provides a file specification for the file. The default file type is .XXE. No wildcard characters are allowed in the file specification.

LINK

By default, an executable image file is created with a file name comprising up to the first 39 characters of the first unit name specified.

/KEEP (D)

/NOKEEP

Controls whether the batch log file generated is deleted after it is printed when the LINK command is executed in batch mode (LINK/SUBMIT).

By default, the log file is not deleted.

/LOG

/NOLOG (D)

Controls whether a list of all the units included in the executable image is displayed. The display shows the units according to the order of elaboration for the program.

By default, a list of all the units included in the executable image is not displayed.

/MAIN (D)

/NOMAIN

Controls where the image transfer address is to be found.

The /MAIN qualifier indicates that the XD Ada unit specified determines the image transfer address, and hence is to be a main program.

The /NOMAIN qualifier indicates that the image transfer address comes from one of the files specified, and not from one of the XD Ada units specified.

By default (/MAIN), only one XD Ada unit can be specified, and that unit must be an XD Ada main program.

/MAP[= file-spec]

/NOMAP (D)

Controls whether the builder creates an image map file and optionally provides a file specification for the file. The default directory for the image map file is the current directory. The default file name comprises up to the first 39 characters of the first unit name specified. The default file type is .MAP. No wildcard characters are allowed in the file specification.

If neither the /BRIEF nor the /FULL qualifier is specified with the /MAP qualifier, /BRIEF is assumed.

LINK

By default, no image map file is created.

/NAME = *job-name*

Specifies a string to be used as the job name and as the file name for the batch log file when the LINK command is executed in batch mode (LINK/SUBMIT). The job name can have from 1 to 39 characters.

By default, if you do not specify the /NAME qualifier, XDACS creates a job name comprising up to the first 39 characters of the first unit name specified. If you specify LINK/NOMAIN but do not specify the /NAME qualifier, and you use a wildcard character in the first unit name specified, the program library manager uses the default file name XDACS_LINK. In these cases, the job name is also the file name of the batch log file.

/NOTIFY (D)

/NONOTIFY

Controls whether a message is broadcast when the LINK command is executed in batch mode (LINK/SUBMIT). The message is broadcast to any terminal at which you are logged in, notifying you that your job has been completed or terminated

By default, a message is broadcast.

OUTPUT = *file-spec*

Requests that any output generated before the builder is invoked be written to the file specified rather than to SYS\$OUTPUT. Any diagnostic messages are written to both SYS\$OUTPUT and the file.

The default directory is the current default directory. If you specify a file type but omit the file name, the default file name is XDACS. The default file type is .LIS. No wildcard characters are allowed in the file specification.

By default, the LINK command output is written to SYS\$OUTPUT.

/PRINTER[= *queue-name*]

/NOPRINTER (D)

Controls whether the log file is queued for printing when the LINK command is executed in batch mode (LINK/SUBMIT) and the batch job is completed.

The /PRINTER qualifier allows you to specify a particular print queue. The default print queue for the log file is SYS\$PRINT.

LINK

By default, the log file is not queued for printing. If you specify **/NOPRINTER**, **/KEEP** is assumed.

/QUEUE = queue-name

Specifies the batch job queue in which the job is entered when the **LINK** command is executed in batch mode (**LINK/SUBMIT**).

By default, if the **/QUEUE** qualifier is not specified, the job is placed in the default system batch job queue, **SYSSBATCH**.

/SELECTIVE (D)

/NOSELECTIVE

Specifies whether selective linking is performed.

Performing selective linking ensures that only subprograms that are called will be linked into the program image. Subprograms within the closure of the main program that are not actually called will be omitted from the image file. Selective linking produces a program image that has been optimized according to size.

Non-selective linking ensures that all defined subprograms are linked into the image.

By default, selective linking is performed.

/SUBMIT

Directs XDACS to submit the command file generated for the builder to a batch queue. You can continue to issue commands in your current process without waiting for the batch job to complete. The builder output is written to a batch log file.

By default, the generated command file is executed in a subprocess (**LINK/WAIT**).

/WAIT

Directs XDACS to execute the command file generated for the builder in a subprocess. Execution of your current process is suspended until the subprocess completes. The builder output is written directly to your terminal. Note that process logical names are propagated to the subprocess generated to execute the command file.

By default, XDACS executes the command file generated for the builder in a subprocess: you must wait for the subprocess to terminate before you can issue another command.

LINK

Parameter Qualifiers

/LIBRARY

Indicates that the associated input file is an object module library to be searched for modules to resolve any undefined symbols in the input files. The default file type is .XLB.

By default, if you do not specify the /LIBRARY qualifier, the file is assumed to be an object file with a default file type of .XOB.

/MAPPING

Indicates that the associated input file is a mapping definition file. Mapping definition files control the location of the program on the target system. The default file type is .MPD.

By default, if you do not specify the /MAPPING qualifier, the file is assumed to be an object file with a default file type of .XOB.

/TARGET

Indicates that the associated input file is a target definition file. Target definition files describe the target system's memory. The default file type is .TGD.

By default, if you do not specify the /TARGET qualifier, the file is assumed to be an object file with a default file type of .XOB.

Examples

1. XDACS> LINK CONTROL_LOOP

%ACS-I-CL_LINKING, Invoking the XD Ada Builder

The LINK command forms the closure of the unit CONTROL_LOOP, which is an XD Ada main program, creates a builder command file and package elaboration file, then invokes the command file in a spawned subprocess.

2. XDACS> LINK/SUBMIT CONTROL_LOOP LOOP_FUNCTIONS/LIBRARY

%ACS-I-CL_SUBMITTED, Job CONTROL_LOOP (queue ALL_BATCH, entry 134) started on FAST_BATCH

The LINK command instructs the builder to link the closure of the XD Ada main program CONTROL_LOOP against the library LOOP_FUNCTIONS.XLB. The /SUBMIT qualifier causes XDACS to submit the builder command file as a batch job.

LINK

3. XDACS> LINK/NOMAIN FLUID_VOLUME,COUNTER MONITOR.XOB
%ACS-I-CL_LINKING, Invoking the XD Ada Builder

The LINK command builds the XD Ada units FLUID_VOLUME and COUNTER with the foreign object file MONITOR.XOB. The /NOMAIN qualifier tells the builder that the image transfer address is in the foreign file.

APPENDIX C

APPENDIX F OF THE Ada STANDARD

The only allowed implementation dependencies correspond to implementation-dependent pragmas, to certain machine-dependent conventions as mentioned in Chapter 13 of the Ada Standard, and to certain allowed restrictions on representation clauses. The implementation-dependent characteristics of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this Appendix are to compiler documentation and not to this report. Implementation-specific portions of the package STANDARD, which are not a part of Appendix F, are:

package STANDARD is

type INTEGER is range $-2^{15} .. (2^{15})-1$;

type LONG_INTEGER is range $-2^{31} .. (2^{31})-1$;

type FLOAT is digits 6 range $-(2^{128} - 2^{106}) .. (2^{128} - 2^{106})$;

type LONG_FLOAT is digits 9 range $-(2^{128} - 2^{96}) .. (2^{128} - 2^{96})$;

type DURATION is delta 1.0E-4 range -131072.0000 .. 131071.9999;

end STANDARD;

Implementation-Dependent Characteristics

NOTE

This appendix is not part of the standard definition of the Ada programming language.

This appendix summarizes the following implementation-dependent characteristics of XD Ada:

- Listing the XD Ada pragmas and attributes.
- Giving the specification of the package **SYSTEM**.
- Presenting the restrictions on representation clauses and unchecked type conversions.
- Giving the conventions for names denoting implementation-dependent components in record representation clauses.
- Giving the interpretation of expressions in address clauses.
- Presenting the implementation-dependent characteristics of the input-output packages.
- Presenting other implementation-dependent characteristics.

F.1 Implementation-Dependent Pragmas

XD Ada provides the following pragmas, which are defined elsewhere in the text. In addition, XD Ada restricts the predefined language pragmas `INLINE` and `INTERFACE`, provides pragma `VOLATILE` in addition to pragma `SHARED`, and provides pragma `SUPPRESS_ALL` in addition to pragma `SUPPRESS`. See Annex B for a descriptive pragma summary.

- `CALL_SEQUENCE_FUNCTION` (see Annex B)
- `CALL_SEQUENCE_PROCEDURE` (see Annex B)
- `EXPORT_EXCEPTION` (see Section 13.9a.3.2)
- `EXPORT_FUNCTION` (see Section 13.9a.1.2)
- `EXPORT_OBJECT` (see Section 13.9a.2.2)
- `EXPORT_PROCEDURE` (see Section 13.9a.1.2)
- `IMPORT_EXCEPTION` (see Section 13.9a.3.1)
- `IMPORT_FUNCTION` (see Section 13.9a.1.1)
- `IMPORT_OBJECT` (see Section 13.9a.2.1)
- `IMPORT_PROCEDURE` (see Section 13.9a.1.1)
- `LEVEL` (see Section 13.5.1)
- `LINK_OPTION` (see Annex B)
- `SUPPRESS_ALL` (see Section 11.7)
- `TITLE` (see Annex B)
- `VOLATILE` (see Section 9.11)

F.2 Implementation-Dependent Attributes

XD Ada provides the following attributes, which are defined elsewhere in the text. See Appendix A for a descriptive attribute summary.

- `BIT` (see Section 13.7.2)
- `MACHINE_SIZE` (see Section 13.7.2)
- `TYPE_CLASS` (see Section 13.7a.2)

F.3 Specification of the Package System

The package SYSTEM for the MIL-STD-1750A is as follows:

F.3.1 Package System for the MIL-STD-1750A Target

package SYSTEM is

```
    type NAME is (MIL_STD_1750A);

    SYSTEM_NAME      : constant NAME := MIL_STD_1750A;
    STORAGE_UNIT     : constant := 16;
    MEMORY_SIZE      : constant := 2**17;
    MIN_INT           : constant := -(2**31);
    MAX_INT           : constant := 2**31-1;
    MAX_DIGITS        : constant := 9;
    MAX_MANTISSA      : constant := 31;
    FINE_DELTA        : constant := 2.0*(-31);
    TICK              : constant := 100.0E-6;
    subtype PRIORITY is INTEGER range 0 .. 15;

    subtype LEVEL is INTEGER range 0 .. 7;

-- Address type
--
    type ADDRESS is private;

    ADDRESS_ZERO : constant ADDRESS;
    type ADDRESS_INT is range -32768 .. 32767;
    function TO_ADDRESS      (X : ADDRESS_INT)      return ADDRESS;
    function TO_ADDRESS      (X : {universal_integer}) return ADDRESS;
    function TO_ADDRESS_INT  (X : ADDRESS)          return ADDRESS_INT;

    function "+" (LEFT : ADDRESS;    RIGHT : ADDRESS_INT) return ADDRESS;
    function "+" (LEFT : ADDRESS_INT; RIGHT : ADDRESS)    return ADDRESS;
    function "-" (LEFT : ADDRESS;    RIGHT : ADDRESS)    return ADDRESS_INT;
    function "-" (LEFT : ADDRESS;    RIGHT : ADDRESS_INT) return ADDRESS;

-- function "=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
-- function "/=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
-- function "<" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
-- function "<=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
-- function ">" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
-- function ">=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;

--
-- Note that because ADDRESS is a private type
-- the functions "=" and "/=" are already available
```

```

-- Generic functions used to access memory
--
generic
  type TARGET is private;
  function FETCH_FROM_ADDRESS (A : ADDRESS) return TARGET;
generic
  type TARGET is private;
  procedure ASSIGN_TO_ADDRESS (A : ADDRESS; T : TARGET);
  type TYPE_CLASS is (TYPE_CLASS_ENUMERATION,
    TYPE_CLASS_INTEGER,
    TYPE_CLASS_FIXED_POINT,
    TYPE_CLASS_FLOATING_POINT,
    TYPE_CLASS_ARRAY,
    TYPE_CLASS_RECORD,
    TYPE_CLASS_ACCESS,
    TYPE_CLASS_TASK,
    TYPE_CLASS_ADDRESS);

--
-- XD Ada hardware-oriented types and functions
--
type BIT_ARRAY is array (INTEGER range <>) of BOOLEAN;
pragma PACK(BIT_ARRAY);
subtype BIT_ARRAY_16 is BIT_ARRAY (0 .. 15);
subtype BIT_ARRAY_32 is BIT_ARRAY (0 .. 31);

type UNSIGNED_WORD is range 0 .. 65535;
for UNSIGNED_WORD'SIZE use 16;

function "not" (LEFT : UNSIGNED_WORD) return UNSIGNED_WORD;
function "and" (LEFT, RIGHT : UNSIGNED_WORD) return UNSIGNED_WORD;
function "or" (LEFT, RIGHT : UNSIGNED_WORD) return UNSIGNED_WORD;
function "xor" (LEFT, RIGHT : UNSIGNED_WORD) return UNSIGNED_WORD;

function TO_UNSIGNED_WORD (X : BIT_ARRAY_16) return UNSIGNED_WORD;
function TO_BIT_ARRAY_16 (X : UNSIGNED_WORD) return BIT_ARRAY_16;

type UNSIGNED_WORD_ARRAY is array (INTEGER range <>) of UNSIGNED_WORD;

type UNSIGNED_LONGWORD is range MIN_INT .. MAX_INT;
for UNSIGNED_LONGWORD'SIZE use 32;

function "not" (LEFT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;
function "and" (LEFT, RIGHT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;
function "or" (LEFT, RIGHT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;
function "xor" (LEFT, RIGHT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;

function TO_UNSIGNED_LONGWORD (X : BIT_ARRAY_32) return UNSIGNED_LONGWORD;
function TO_BIT_ARRAY_32 (X : UNSIGNED_WORD) return BIT_ARRAY_32;

type UNSIGNED_LONGWORD_ARRAY is array (INTEGER range <>) of UNSIGNED_LONGWORD;

```

F-4 Implementation-Dependent Characteristics

```
-- Conventional names for static subtypes of type UNSIGNED_LONGWORD
```

```
--
```

```
subtype UNSIGNED_1 is UNSIGNED_LONGWORD range 0 .. 2** 1-1;  
subtype UNSIGNED_2 is UNSIGNED_LONGWORD range 0 .. 2** 2-1;  
subtype UNSIGNED_3 is UNSIGNED_LONGWORD range 0 .. 2** 3-1;  
subtype UNSIGNED_4 is UNSIGNED_LONGWORD range 0 .. 2** 4-1;  
subtype UNSIGNED_5 is UNSIGNED_LONGWORD range 0 .. 2** 5-1;  
subtype UNSIGNED_6 is UNSIGNED_LONGWORD range 0 .. 2** 6-1;  
subtype UNSIGNED_7 is UNSIGNED_LONGWORD range 0 .. 2** 7-1;  
subtype UNSIGNED_8 is UNSIGNED_LONGWORD range 0 .. 2** 8-1;  
subtype UNSIGNED_9 is UNSIGNED_LONGWORD range 0 .. 2** 9-1;  
subtype UNSIGNED_10 is UNSIGNED_LONGWORD range 0 .. 2**10-1;  
subtype UNSIGNED_11 is UNSIGNED_LONGWORD range 0 .. 2**11-1;  
subtype UNSIGNED_12 is UNSIGNED_LONGWORD range 0 .. 2**12-1;  
subtype UNSIGNED_13 is UNSIGNED_LONGWORD range 0 .. 2**13-1;  
subtype UNSIGNED_14 is UNSIGNED_LONGWORD range 0 .. 2**14-1;  
subtype UNSIGNED_15 is UNSIGNED_LONGWORD range 0 .. 2**15-1;  
subtype UNSIGNED_16 is UNSIGNED_LONGWORD range 0 .. 2**16-1;  
subtype UNSIGNED_17 is UNSIGNED_LONGWORD range 0 .. 2**17-1;  
subtype UNSIGNED_18 is UNSIGNED_LONGWORD range 0 .. 2**18-1;  
subtype UNSIGNED_19 is UNSIGNED_LONGWORD range 0 .. 2**19-1;  
subtype UNSIGNED_20 is UNSIGNED_LONGWORD range 0 .. 2**20-1;  
subtype UNSIGNED_21 is UNSIGNED_LONGWORD range 0 .. 2**21-1;  
subtype UNSIGNED_22 is UNSIGNED_LONGWORD range 0 .. 2**22-1;  
subtype UNSIGNED_23 is UNSIGNED_LONGWORD range 0 .. 2**23-1;  
subtype UNSIGNED_24 is UNSIGNED_LONGWORD range 0 .. 2**24-1;  
subtype UNSIGNED_25 is UNSIGNED_LONGWORD range 0 .. 2**25-1;  
subtype UNSIGNED_26 is UNSIGNED_LONGWORD range 0 .. 2**26-1;  
subtype UNSIGNED_27 is UNSIGNED_LONGWORD range 0 .. 2**27-1;  
subtype UNSIGNED_28 is UNSIGNED_LONGWORD range 0 .. 2**28-1;  
subtype UNSIGNED_29 is UNSIGNED_LONGWORD range 0 .. 2**29-1;

```

```
-- Not shown
```

```
end SYSTEM;
```

F.4 Restrictions on Representation Clauses

The representation clauses allowed in XD Ada are length, enumeration, record representation, and address clauses.

F.5 Conventions for Implementation-Generated Names Denoting Implementation-Dependent Components in Record Representation Clauses

XD Ada does not allocate implementation-dependent components in records.

F.6 Interpretation of Expressions Appearing in Address Clauses

Expressions appearing in address clauses must be of the type ADDRESS defined in package SYSTEM (see Section 13.7a.1 and Section F.3).

XD Ada allows address clauses for variables (see Section 13.5). For address clauses on variables, the address expression is interpreted as a MIL-STD-1750A 16-bit logical address.

XD Ada supports address clauses on task entries to allow interrupts to cause a reschedule directly. For address clauses on task entries, the address expression is interpreted as a MIL-STD-1750A interrupt number in the range 0 .. 15.

In XD Ada for MIL-STD-1750A, values of type SYSTEM.ADDRESS are interpreted as integers in the range $-2^{15} \dots 2^{15} - 1$. As SYSTEM.ADDRESS is a private type, the only operations allowed on objects of this type are those given in package SYSTEM.

F.7 Restrictions on Unchecked Type Conversions

XD Ada supports the generic function UNCHECKED_CONVERSION with the restrictions given in Section 13.10.2.

F.8 Implementation-Dependent Characteristics of Input-Output Packages

The packages `SEQUENTIAL_IO` and `DIRECT_IO` are implemented as null packages that conform to the specification given in the *Reference Manual for the Ada Programming Language*. The packages raise the exceptions specified in Chapter 14 of the *Reference Manual for the Ada Programming Language*. The three possible exceptions that are raised by these packages are given here, in the order in which they are raised.

Exception	When Raised
<code>STATUS_ERROR</code>	Raised by an attempt to operate upon or close a file that is not open (no files can be opened).
<code>NAME_ERROR</code>	Raised if a file name is given with a call of <code>CREATE</code> or <code>OPEN</code> .
<code>USE_ERROR</code>	Raised if exception <code>STATUS_ERROR</code> is not raised.

`MODE_ERROR` cannot be raised since no file can be opened (therefore it cannot have a current mode).

The predefined package `LOW_LEVEL_IO` is provided.

F.8.1 The Package `TEXT_IO`

The package `TEXT_IO` conforms to the specification given in the *Reference Manual for the Ada Programming Language*. String input-output is implemented as defined. File input-output is supported to `STANDARD_INPUT` and `STANDARD_OUTPUT` only. The possible exceptions that are raised by package `TEXT_IO` are as follows:

Exception	When Raised
STATUS_ERROR	Raised by an attempt to operate upon or close a file that is not open (no files can be opened).
NAME_ERROR	Raised if a file name is given with a call of CREATE or OPEN.
MODE_ERROR	Raised by an attempt to read from, or test for the end of, STANDARD_OUTPUT, or to write to STANDARD_INPUT.
END_ERROR	Raised by an attempt to read past the end of STANDARD_INPUT.
USE_ERROR	Raised when an unsupported operation is attempted, that would otherwise be legal.

The type COUNT is defined as follows:

```
type COUNT is range 0 .. INTEGER'LAST;
```

The subtype FIELD is defined as follows:

```
type FIELD is INTEGER range 0 .. 132;
```

F.8.2 The Package IO_EXCEPTIONS

The specification of the package IO_EXCEPTIONS is the same as that given in the *Reference Manual for the Ada Programming Language*.

F.9 Other Implementation Characteristics

Implementation characteristics associated with the definition of a main program, various numeric ranges, and implementation limits are summarized in the following sections.

F.9.1 Definition of a Main Program

Any library procedure can be used as a main program provided that it has no formal parameters.

F.9.2 Values of Integer Attributes

The ranges of values for integer types declared in package STANDARD are as follows:

INTEGER	$-2^{15} .. 2^{15} - 1$	(-32768 .. 32767)
LONG_INTEGER	$-2^{31} .. 2^{31} - 1$	(-2147483648 .. 2147483647)

For the package TEXT_IO, the range of values for types COUNT and FIELD are as follows:

COUNT	$0 .. 2^{15} - 1$	(0 .. 32767)
FIELD	$0 .. 132$	

F.9.3 Values of Floating-Point Attributes

Floating-point types are described in Section 3.5.7. The representation attributes of floating-point types are summarized in the following table:

	FLOAT	LONG_FLOAT
DIGITS	6	9
SIZE	32	48
MANTISSA	21	31
EMAX	84	124
EPSILON	2^{-20}	2^{-30}
SMALL	2^{-85}	2^{-125}
LARGE	$2^{84}-2^{63}$	$2^{124}-2^{93}$
SAFE_EMAX	127	127
SAFE_SMALL	2^{-126}	2^{-126}
SAFE_LARGE	$2^{127}-2^{106}$	$2^{127}-2^{96}$
FIRST	$-(2^{128}-2^{106})$	$-(2^{128}-2^{96})$
LAST	$2^{128}-2^{106}$	$2^{128}-2^{96}$
MACHINE_RADIX	2	2
MACHINE_MANTISSA	23	39
MACHINE_EMAX	127	127
MACHINE_EMIN	-128	128
MACHINE_ROUNDS	FALSE	FALSE
MACHINE_OVERFLOWS	FALSE	FALSE

F.9.4 Attributes of Type DURATION

The values of the significant attributes of type DURATION are as follows:

DURATION'DELTA	1.E-4	(10 ⁻⁴)
DURATION'SMALL	2#1.0#E-14	(2 ⁻¹⁴)
DURATION'FIRST	-131072.0000	(-2 ¹⁷)
DURATION'LAST	131071.9999	(2 ¹⁷ - 'DELTA)

F.9.5 Implementation Limits

Limit	Description
255	Maximum identifier length (number of characters)
255	Maximum number of characters in a source line
2 ¹⁰	Maximum number of library units and subunits in a compilation closure ¹
2 ¹²	Maximum number of library units and subunits in an execution closure ²
2 ¹⁶ - 1	Maximum number of enumeration literals in an enumeration type definition
2 ¹⁶ - 1	Maximum number of lines in a source file
2 ¹⁵ x 16	Maximum number of bits in any object
2 ¹⁶ - 1	Maximum number of exceptions

¹The compilation closure of a given unit is the total set of units that the given unit depends on, directly and indirectly.

²The execution closure of a given unit is the compilation closure plus all associated secondary units.

Implementation-Dependent Characteristics

This appendix describes Version 1.2 additions to the range of implementation-dependent pragmas.

F.1 Implementation-Dependent Pragmas

XD Ada MIL-STD-1750A Version 1.2 supplies three new pragmas, `DIRECT_INTERRUPT_ENTRY`, `IDENT` and `TIME_SLICE`. In the following full list of supported pragmas, references refer to sections in the *XD Ada MIL-STD-1750A Supplement to the Ada Language Reference Manual*, unless updated by sections supplied in this manual.

- `CALL_SEQUENCE_FUNCTION` (see Annex B)
- `CALL_SEQUENCE_PROCEDURE` (see Annex B)
- `DIRECT_INTERRUPT_ENTRY` (see Section 13.5.1)
- `EXPORT_EXCEPTION` (see Section 13.9a.3.2)
- `EXPORT_FUNCTION` (see Section 13.9a.1.2)
- `EXPORT_OBJECT` (see Section 13.9a.2.2)
- `EXPORT_PROCEDURE` (see Section 13.9a.1.2)
- `IDENT` (see Annex B)
- `IMPORT_EXCEPTION` (see Section 13.9a.3.1)
- `IMPORT_FUNCTION` (see Section 13.9a.1.1)
- `IMPORT_OBJECT` (see Section 13.9a.2.1)
- `IMPORT_PROCEDURE` (see Section 13.9a.1.1)

- LEVEL (see Section 13.5.1)
- LINK_OPTION (see Annex B)
- SUPPRESS_ALL (see Section 11.7)
- TITLE (see Annex B)
- TIME_SLICE (see Section 9.8a)
- VOLATILE (see Section 9.11)

Representation Clauses and Implementation-Dependent Features

Supplementary XD Ada information is provided for Sections 13.1, 13.2, 13.3, 13.4, 13.5, 13.5.1, 13.7, 13.7.1, 13.7.2, 13.7.3, 13.8, 13.9, 13.10.1 and 13.10.2. Two additional sections, Section 13.7a and Section 13.9a, provide XD Ada information on the package SYSTEM and on the XD Ada import and export pragmas.

13.1 Representation Clauses

The following information supplements paragraphs 4 and 8:

In XD Ada, an address clause can only apply to a variable or a single entry; an address clause cannot apply to a constant, subprogram, package, or task unit. See Section 13.5 for further explanation.

The following information supplements paragraph 13:

Pragma PACK is implemented in XD Ada. As the behavior of pragma PACK is implementation dependent, users are advised to use representation clauses to ensure a particular representation across targets.

In XD Ada, all array and record components are aligned on word boundaries by default; the effect of pragma PACK on a record or array is to cause those components that are packable to be allocated in adjacent bits without regard to word boundaries. Whether any particular component is packable depends on the rules for its type; the *XD Ada MIL-STD-1750A Run-Time Reference Manual* gives information on which

types can be packed as components of composite types, as well as information on how these types are packed.

A record component that begins a variant is always allocated at the next word boundary; a variant that begins on other than a word boundary can be obtained only with a record representation clause.

XD Ada provides no additional representation pragmas.

The following information supplements paragraph 14:

XD Ada does not allow a representation clause for a type that depends on a generic formal type. A type depends on a generic formal type if it has a subcomponent of a generic formal type or a subcomponent that depends on a generic formal type, or if it is derived from a generic formal type or a type that depends on a generic formal type.

13.2 Length Clauses

The following information supplements paragraph 6:

In XD Ada, for a discrete type, the given size must not exceed 32 (bits). The given size becomes the default allocation for all objects and components (in arrays and records) of that type. However, sizes of objects may be increased by the compiler for optimization purposes.

For integer and enumeration types, the given size affects the internal representation as follows: for integer types, high order bits are sign-extended; for enumeration types, the high order bits may be either zero- or sign-extended depending upon the base representation that is selected. For all other types, the given size must equal the size that would apply in the absence of a size specification.

The following information supplements paragraph 8:

The specification of a collection size is interpreted as follows. If the value of the expression is greater than or equal to zero, the specified size is then used as the initial size of the collection; the collection is not extended should that initial allocation be exhausted. In the absence of a T'SORAGE_SIZE, no storage is initially allocated for the collection; storage is allocated from the heap as needed, until all heap memory is exhausted. If the value is less than zero, the exception CONSTRAINT_ERROR is raised.

The following information supplements paragraph 10:

A task storage specification overrides the default task storage size. The specification is interpreted as follows. If the value of the expression is

greater than zero, the specified size determines the number of storage units (words) to be allocated for an activation of the task of the given type. In the absence of a T'SORAGE_SIZE, a default allocation is used. If the value is less than zero, the exception CONSTRAINT_ERROR is raised.

The following information supplements paragraphs 8 and 10:

NOTE

The *XD Ada MIL-STD-1750A Run-Time Reference Manual* discusses task and access type storage and storage allocation in more detail.

The following information supplements paragraph 12:

Arbitrary values of *small* are not accepted.

13.3 Enumeration Representation Clauses

The following information supplements paragraph 4:

In XD Ada, the only specific restriction on enumeration representation clauses is that each expression for an integer code must have a value in the range MIN_INT .. MAX_INT.

13.4 Record Representation Clauses

The following information supplements paragraph 4:

For statically allocated objects and for objects allocated from a collection in XD Ada, the simple expression in an alignment clause must be a power of two. The upper limit is 2^{16} . The alignment then occurs at a location that is a number of words times the value of the simple expression: a value of 1 causes word alignment, a value of 2 causes longword alignment, and so on.

Further restrictions apply for objects declared within a subprogram, where XD Ada restricts the alignment to mod 1. In other words, stack-allocated objects can only be word aligned.

Bit-alignable representation clauses are provided for discrete types, arrays of discrete types, and record types.

See the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for information on how objects are allocated.

The following information supplements paragraph 5:

A component clause specifies the *storage place* of a component relative to the start of the record. In XD Ada for MIL-STD-1750A targets, the size of a storage unit (SYSTEM.STORAGE_UNIT) is 16 bits (one word). If the number of bits specified by the range is sufficient for the component subtype, the requested size and placement of the field is observed (and overlaps storage boundaries if necessary); otherwise, the specification is illegal. For a component of a discrete type, the number of bits must not exceed 32; for a component of any other type, the size must not exceed the actual size of the component. See the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for information about determining the number of bits that are sufficient for any given subtype.

Component values in XD Ada are biased when a component clause requires a very small component storage space; each value stored is the unsigned quantity formed by subtracting COMPONENT_SUBTYPE·FIRST from the original value. See the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for more detailed information.

Component clauses in XD Ada are restricted as follows. Any component that is not packable must be allocated on a word boundary. Components that are packable can be allocated without restriction. See the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for a definition and description of packable components.

The following information supplements paragraph 6:

Components named in a component clause are allocated first; then, unnamed components are allocated in the order in which they are written in the record type declaration. Variants can be overlapped. If pragma PACK is specified, packed allocation rules (see Section 13.1) are used; otherwise, unpacked allocation is used.

The following information supplements paragraph 8:

XD Ada generates no implementation-dependent components or names.

The following information supplements the Notes section:

The example of record representation and address clauses in the *Reference Manual for the Ada Programming Language* is not relevant for XD Ada as it assumes that type ADDRESS is represented in 24 bits, whereas in XD Ada type ADDRESS is represented in 16 bits. The following example is appropriate to XD Ada:

Example:

```

type CONDITION_CODE is (C,P,Z,N);
type CONDITION_CODES is array (CONDITION_CODE) of BOOLEAN;
pragma PACK (CONDITION_CODES);

type PROGRAM_STATUS_WORD is
  record
    CS      : CONDITION_CODES
    RESERVED : INTEGER range 0 .. 15;
    PS      : INTEGER range 0 .. 15;
    AS      : INTEGER range 0 .. 15;
  end record;

for PROGRAM_STATUS_WORD use
  record at mod 1;
    CS      at 0 range 0  .. 3;
    RESERVED at 0 range 4  .. 7;
    PS      at 0 range 8  .. 11;
    AS      at 0 range 12 .. 15;
  end record;
for PROGRAM_STATUS_WORD'SIZE use 1 * SYSTEM.STORAGE_UNIT;

```

Note on the example:

The record representation clause defines the record layout. The length clause guarantees that exactly one storage unit is used.

Component Specification Example:

```

subtype S is INTEGER range 10 .. 13;

type REC is
  record
    X : S;
    Y : S;
  end record;

for REC use
  record
    X at 0 range 0 .. 3;  -- legal because 4 bits
                          -- are sufficient
    Y at 0 range 4 .. 4;  -- illegal because 1 bit is
                          -- not enough to represent
                          -- an integer of subtype S
  end record;

```

Notes on the example:

The subtype declaration in this example implies an integer with a minimum size of four bits. However, the components X and Y of subtype S are biased and can be stored in only two bits. The component clause for X is legal because it requires at least the minimum number of bits required for the integer subtype; the component clause for Y is illegal because it does not allow enough bits to represent the integer subtype.

13.5 Address Clauses

The following information supplements paragraph 7:

Like VAX Ada, XD Ada supports address clauses.

In XD Ada, the simple name must be the name of a variable. XD Ada does not allow address clauses that name constants; or subprogram, package, or task units.

An intermediate pointer is created only if the resulting address is not a compile-time constant.

The placement of an address clause in XD Ada must follow the rules given in Section 13.1. In other words, the clause and the variable declaration must both occur immediately within the same declarative part or package specification, and the declaration must occur before the clause. The restrictions for forcing occurrences also apply; with respect to address clauses, any occurrence of the variable name after its declaration is a forcing occurrence.

Address clauses are not allowed in combination with any of the XD Ada pragmas for importing or exporting objects. If used in such cases, the pragma involved is ignored.

The following information supplements the Notes section:

Also, if an address clause is specified for an object of a type that has been declared with an alignment clause, the alignment required for the address is checked against the alignment given for the record type. If the two are incompatible, the exception PROGRAM_ERROR is raised.

The same check applies to a type that contains a component of a type that has been declared with an alignment clause (the alignment of the component forces the alignment of the containing type).

13.5.1 Interrupts

The following information supplements all of this section:

Unlike VAX Ada, XD Ada supports interrupts. The address in the use clause is the 1750A interrupt number.

XD Ada provides the additional pragma `LEVEL`. This pragma is given for a task type, or single task of anonymous type, and gives the level for its interrupts.

There are two ways an interrupt entry can be handled, according to whether or not the task has a pragma `LEVEL`. The *XD Ada MIL-STD-1750A Run-Time Reference Manual* gives examples of interrupt handlers.

Tasks with interrupt entries but no pragma run at interrupt level whilst accepting an interrupt in a rendezvous. Other interrupts of the same level or lower levels are inhibited. It is possible to lose interrupts with this method.

Tasks with interrupt entries and a pragma `LEVEL` always run at interrupt level, whether inside or outside a rendezvous. This enables the user to avoid losing interrupts.

An interrupt entry to a task with the pragma behaves like an ordinary entry call. An interrupt entry to a task with no pragma behaves like a conditional entry call. If there is an accept statement waiting for the interrupt, the body of the accept statement is executed immediately. When the body is complete, the task is inserted in the ready queue and the interrupt completed by a return-from-interrupt instruction. The accept statement can make excursions into other routines, and can even make entry calls, but must not suspend the task before the interrupt is dismissed, otherwise the program repeatedly services the interrupt unsuccessfully.

Writing interrupt handlers in XD Ada requires detailed knowledge of the behavior of the target computer's interrupt system. It is not possible simply to place a use clause on an entry to achieve the desired effect.

13.7 The Package System

The following information supplements paragraph 1:

XD Ada additions to the package SYSTEM are described in Section 13.7a.

The following information supplements paragraph 3:

Addresses are treated as 16-bit logical addresses as represented on the target in a register or memory location. The physical address is determined by the page registers and the address state.

The following information supplements paragraph 5:

In XD Ada, the enumeration literal for SYSTEM_NAME is MIL-STD-1750A.

The following information supplements paragraph 7:

In XD Ada, the value given for STORAGE_UNIT must be 16 (bits).

The following information supplements paragraph 9:

In XD Ada, the number given for MEMORY_SIZE must be 131072. Like VAX Ada, XD Ada does not provide support for checking or ensuring that the given size is not exceeded.

The following information supplements paragraph 11:

As with VAX Ada, XD Ada imposes no further limitations on these pragmas. To reduce the amount of recompilation required, XD Ada identifies those units that have a real dependence on the values affected by these pragmas; only such units must be recompiled. In particular, predefined XD Ada packages do not depend on the values affected by these pragmas, and none require recompilation if these pragmas are used.

13.7a XD Ada Additions to the Package SYSTEM

In addition to the language-required declarations in package SYSTEM, XD Ada declares the operations, constants, types, and subtypes described in the following sections.

13.7a.1 Properties of the Type ADDRESS

In XD Ada, ADDRESS is a private type for which the following operations are declared:

```
-- Address type
--
type ADDRESS is private;
ADDRESS_ZERO : constant ADDRESS;
type ADDRESS_INT is range -32768 .. 32767;

function TO_ADDRESS      (X : ADDRESS_INT)      return ADDRESS;
function TO_ADDRESS      (X : (universal_integer)) return ADDRESS;
function TO_ADDRESS_INT  (X : ADDRESS)          return ADDRESS_INT;

function "+" (LEFT : ADDRESS;    RIGHT : ADDRESS_INT) return ADDRESS;
function "+" (LEFT : ADDRESS_INT; RIGHT : ADDRESS)    return ADDRESS;
function "-" (LEFT : ADDRESS;    RIGHT : ADDRESS_INT) return ADDRESS_INT;
function "-" (LEFT : ADDRESS_INT; RIGHT : ADDRESS)    return ADDRESS;
function "-" (LEFT : ADDRESS;    RIGHT : ADDRESS_INT) return ADDRESS;
function "-" (LEFT : ADDRESS_INT; RIGHT : ADDRESS)    return ADDRESS;

-- function "=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
-- function "/=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
function "<" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
function "<=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
function ">" (LEFT, RIGHT : ADDRESS) return BOOLEAN;
function ">=" (LEFT, RIGHT : ADDRESS) return BOOLEAN;

--
-- Note that because ADDRESS is a private type
-- the functions "=" and "/=" are already available

-- Generic functions used to access memory
--
generic
  type TARGET is private;
function FETCH_FROM_ADDRESS (A : ADDRESS) return TARGET;

generic
  type TARGET is private;
procedure ASSIGN_TO_ADDRESS (A : ADDRESS; T : TARGET);
```

The addition, subtraction, and relational functions provide arithmetic and comparative operations for addresses. The generic subprograms `FETCH_FROM_ADDRESS` and `ASSIGN_TO_ADDRESS` provide operations for reading from or writing to a given address interpreted as having any desired type. `ADDRESS_ZERO` is a deferred constant whose value corresponds to the first (machine) address.

In an instantiation of `FETCH_FROM_ADDRESS` or `ASSIGN_TO_ADDRESS`, the actual subtype corresponding to the formal type `T` must not be an unconstrained array type or an unconstrained type with discriminants. If the actual subtype is a type with discriminants, the value fetched by a call of a function resulting from an instantiation of `FETCH_FROM_ADDRESS` is checked to ensure that the discriminants satisfy the constraints of the actual subtype. In any other case, no check is made.

Example:

```
X : INTEGER;
A : SYSTEM.ADDRESS := X'ADDRESS;    -- legal

function FETCH is new FETCH_FROM_ADDRESS(INTEGER);
procedure ASSIGN is new ASSIGN_TO_ADDRESS(INTEGER);

X := FETCH(A);                      -- like "X := A.all;"
ASSIGN(A,X);                        -- like "A.all := X;"
```

13.7a.2 Type Class Enumeration Type

XD Ada declares the following enumeration type for identifying the various Ada type classes:

```
type TYPE_CLASS is (TYPE_CLASS_ENUMERATION,
                    TYPE_CLASS_INTEGER,
                    TYPE_CLASS_FIXED_POINT,
                    TYPE_CLASS_FLOATING_POINT,
                    TYPE_CLASS_ARRAY,
                    TYPE_CLASS_RECORD,
                    TYPE_CLASS_ACCESS,
                    TYPE_CLASS_TASK,
                    TYPE_CLASS_ADDRESS);
```

In addition to the usual operations for discrete types (see Section 3.5.5), XD Ada provides the attribute `TYPE_CLASS`.

For every type or subtype `T`:

`T.TYPE_CLASS` Yields the value of the type class for the full type of `T`. If `T` is a generic formal type, then the value is that for the corresponding actual subtype. The value of this attribute is of the type `TYPE_CLASS`.

This attribute is only allowed if its unit names the predefined package `SYSTEM` in a `with` clause.

Examples:

Given

```
type MY_INT is range 1..10;
type NEW_INT is new STRING;
package PACK is
  type PRIV is private;
private
  type PRIV is new FLOAT;
end PACK;
```

then

```
-- MY_INT'TYPE_CLASS    equals    TYPE_CLASS_INTEGER
-- NEW_INT'TYPE_CLASS    equals    TYPE_CLASS_ARRAY
-- PRIV'TYPE_CLASS       equals    TYPE_CLASS_FLOATING_POINT
```

13.7a.3 Hardware-Oriented Types and Functions

XD Ada declares the following types, subtypes, and functions for convenience in working with MIL-STD-1750A hardware-oriented storage:

```
--
-- XD Ada hardware-oriented types and functions
--
type BIT_ARRAY is array (INTEGER range <>) of BOOLEAN;
pragma PACK(BIT_ARRAY);
subtype BIT_ARRAY_16 is BIT_ARRAY (0 .. 15);
subtype BIT_ARRAY_32 is BIT_ARRAY (0 .. 31);
type UNSIGNED_WORD is range 0 .. 65535;
for UNSIGNED_WORD'SIZE use 16;
function "not" (LEFT : UNSIGNED_WORD) return UNSIGNED_WORD;
function "and" (LEFT, RIGHT : UNSIGNED_WORD) return UNSIGNED_WORD;
function "or" (LEFT, RIGHT : UNSIGNED_WORD) return UNSIGNED_WORD;
function "xor" (LEFT, RIGHT : UNSIGNED_WORD) return UNSIGNED_WORD;

function TO_UNSIGNED_WORD (X : BIT_ARRAY_16) return UNSIGNED_WORD;
function TO_BIT_ARRAY_16 (X : UNSIGNED_WORD) return BIT_ARRAY_16;
type UNSIGNED_WORD_ARRAY is array (INTEGER range <>) of UNSIGNED_WORD;

--
type UNSIGNED_LONGWORD is range MIN_INT .. MAX_INT;
for UNSIGNED_LONGWORD'SIZE use 32;
function "not" (LEFT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;
function "and" (LEFT, RIGHT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;
function "or" (LEFT, RIGHT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;
function "xor" (LEFT, RIGHT : UNSIGNED_LONGWORD) return UNSIGNED_LONGWORD;
```

```

function TO_UNSIGNED_LONGWORD (X : BIT_ARRAY_32) return UNSIGNED_LONGWORD;
function TO_BIT_ARRAY_32 (X : UNSIGNED_WORD) return BIT_ARRAY_32;

type UNSIGNED_LONGWORD_ARRAY is array (INTEGER range <>) of UNSIGNED_LONGWORD;

```

13.7a.4 Conventional Names for Unsigned Longwords

The following XD Ada declarations provide conventional names for static subtypes of the predefined type UNSIGNED_LONGWORD:

```

subtype UNSIGNED_1 is UNSIGNED_LONGWORD range 0 .. 2** 1-1;
subtype UNSIGNED_2 is UNSIGNED_LONGWORD range 0 .. 2** 2-1;
subtype UNSIGNED_3 is UNSIGNED_LONGWORD range 0 .. 2** 3-1;
subtype UNSIGNED_4 is UNSIGNED_LONGWORD range 0 .. 2** 4-1;
subtype UNSIGNED_5 is UNSIGNED_LONGWORD range 0 .. 2** 5-1;
subtype UNSIGNED_6 is UNSIGNED_LONGWORD range 0 .. 2** 6-1;
subtype UNSIGNED_7 is UNSIGNED_LONGWORD range 0 .. 2** 7-1;
subtype UNSIGNED_8 is UNSIGNED_LONGWORD range 0 .. 2** 8-1;
subtype UNSIGNED_9 is UNSIGNED_LONGWORD range 0 .. 2** 9-1;
subtype UNSIGNED_10 is UNSIGNED_LONGWORD range 0 .. 2**10-1;
subtype UNSIGNED_11 is UNSIGNED_LONGWORD range 0 .. 2**11-1;
subtype UNSIGNED_12 is UNSIGNED_LONGWORD range 0 .. 2**12-1;
subtype UNSIGNED_13 is UNSIGNED_LONGWORD range 0 .. 2**13-1;
subtype UNSIGNED_14 is UNSIGNED_LONGWORD range 0 .. 2**14-1;
subtype UNSIGNED_15 is UNSIGNED_LONGWORD range 0 .. 2**15-1;
subtype UNSIGNED_16 is UNSIGNED_LONGWORD range 0 .. 2**16-1;
subtype UNSIGNED_17 is UNSIGNED_LONGWORD range 0 .. 2**17-1;
subtype UNSIGNED_18 is UNSIGNED_LONGWORD range 0 .. 2**18-1;
subtype UNSIGNED_19 is UNSIGNED_LONGWORD range 0 .. 2**19-1;
subtype UNSIGNED_20 is UNSIGNED_LONGWORD range 0 .. 2**20-1;
subtype UNSIGNED_21 is UNSIGNED_LONGWORD range 0 .. 2**21-1;
subtype UNSIGNED_22 is UNSIGNED_LONGWORD range 0 .. 2**22-1;
subtype UNSIGNED_23 is UNSIGNED_LONGWORD range 0 .. 2**23-1;
subtype UNSIGNED_24 is UNSIGNED_LONGWORD range 0 .. 2**24-1;
subtype UNSIGNED_25 is UNSIGNED_LONGWORD range 0 .. 2**25-1;
subtype UNSIGNED_26 is UNSIGNED_LONGWORD range 0 .. 2**26-1;
subtype UNSIGNED_27 is UNSIGNED_LONGWORD range 0 .. 2**27-1;
subtype UNSIGNED_28 is UNSIGNED_LONGWORD range 0 .. 2**28-1;
subtype UNSIGNED_29 is UNSIGNED_LONGWORD range 0 .. 2**29-1;
subtype UNSIGNED_30 is UNSIGNED_LONGWORD range 0 .. 2**30-1;
subtype UNSIGNED_31 is UNSIGNED_LONGWORD range 0 .. 2**31-1;

```

13.7.1 System-Dependent Named Numbers

In XD Ada, the values for system-dependent named numbers are as shown in the following table.

Attribute	MIL-STD-1750A
MIN_INT	-2^{31}
MAX_INT	$2^{31}-1$
MAX_DIGITS	9
MAX_MANTISSA	31
FINE_DELTA	2.0^{-31}
TICK	100.0×10^{-6}

13.7.2 Representation Attributes

The following information supplements all of this section:

For any object, program unit, label, or entry X:

X'ADDRESS Yields the address of the first of the storage elements allocated to X. For a subprogram, package, task unit or label, this value refers to the machine code associated with the corresponding body or statement. For an entry for which an address clause has been given, the value refers to the offset of the interrupt vector from the vector base register. The value of this attribute is of the type ADDRESS defined in the package SYSTEM.

For an object that is a variable, the value is the actual address of the variable (which may be statically or dynamically allocated). This attribute forces a variable to be allocated in memory rather than in a register, and causes the variable to be marked as volatile for the duration of the block statement or body containing use of the attribute. If the location of the variable is not word-aligned, the value is the address of the lowest word that contains the variable. For an object that is a constant, the value is the address of the constant value in memory; however, two occurrences of C'ADDRESS, where

C denotes a constant, may or may not yield the same address value. For an object that is a named number, the value is zero (ADDRESS_ZERO).

NOTE

In the context of these representation attributes, ADDRESS_ZERO means only that no useful interpretation of a nonzero value is currently supported. That is, its use as a result of C'ADDRESS is subject to change.

For an access object, X.all'ADDRESS is the address of the designated object; X.all'ADDRESS is subject to an ACCESS_CHECK for the designated object. For a record component, X.C'ADDRESS is subject to a DISCRIMINANT_CHECK for an object in a variant part. For an array component or slice, X(I)'ADDRESS or X(I1...I2)'ADDRESS is subject to an INDEX_CHECK for the denoted component or slice.

For program units that are task units or package units, the value is zero (ADDRESS_ZERO). For program units that are subprograms, the value is the same as the address that would be exported. (See Section 13.9a.1.4 (LRM) for information on pragmas EXPORT_FUNCTION and EXPORT_PROCEDURE).

For entries, the value is zero (ADDRESS_ZERO).

For labels, the value is the address of the machine code which follows the label.

For any type or subtype X, or for any object X:

X.SIZE

For a type or a subtype, the value is limited to values in the range 0 .. MAX_INT; the exception NUMERIC_ERROR (see Section 11.1) is raised for values outside this range. For an object that is a variable or a constant in XD Ada, the value is its size in bits. For an object that is a named number, the value is zero. For a record component, X.C.SIZE is subject to a DISCRIMINANT_CHECK

for an object in a variant part. For an array component or slice, $X(I)'SIZE$ or $X(I1..I2)'SIZE$ is subject to an `INDEX_CHECK` for the denoted component or slice.

For any type or subtype X :

$X'MACHINE_SIZE$ Yields the number of machine bits to be allocated for variables of the type or subtype. This value takes into account any padding bits used by XD Ada when allocating a variable on a word boundary. The value of this attribute is of the type *universal_integer*.

The value is always a multiple of 16 (bits). In particular, for discrete types it is 16, or 32. The value is limited to the range $0..MAX_INT$; the exception `NUMERIC_ERROR` is raised for values outside this range.

For any object X :

$X'BIT$

Yields the bit offset within the storage unit (word) that contains the first bit of the storage allocated for the object. The value of this attribute is of the type *universal_integer*, and is always in the range $0..15$.

For an object that is a variable or a constant allocated in a register, the value is zero. (The use of this attribute does not force the allocation of a variable to memory.) For an object that is a formal parameter, this attribute applies either to the matching actual parameter or to a copy of the matching actual parameter. For an access object, the value is zero (in the absence of `CONSTRAINT_ERROR`); $X.all'BIT$ is subject to an `ACCESS_CHECK` for the designated object. For a record component, $X.C'BIT$ is subject to a `DISCRIMINANT_CHECK` for a component in a variant part. For an array component or slice, $X(I)'BIT$ or $X(I1..I2)'BIT$ is subject to an `INDEX_CHECK` for the denoted component or slice.

The following information supplements the Notes section:

The attribute `X'MACHINE_SIZE` gives the size that would be used for a variable of the type or subtype; it does not give the size that may be used for a component of that type or subtype.

The machine size of a type or subtype can be influenced by representation clauses, unlike the size of a type or subtype, which is independent of representation clauses. The machine size of a base type can be less than, equal to, or greater than the size of that same base type. See the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for examples and additional discussion.

13.7.3 Representation Attributes of Real Types

The following information supplements paragraphs 3 and 4:

For both fixed- and floating-point types:

`T'MACHINE_ROUNDS` In XD Ada this value is FALSE

`T'MACHINE_OVERFLOWS` In XD Ada this value is FALSE

The XD Ada values of the other representation attributes for floating-point types are dependent on the floating-point type and are listed in Appendix F.

13.8 Machine Code Insertions

The following information supplements paragraph 4:

XD Ada provides the package `MACHINE_CODE`. Machine code insertions can be expanded in line.

This predefined package and not a user-defined package must be named in a `with` clause that applies to the compilation unit in which the code statement occurs.

The following is an example of `MACHINE_CODE` and the `with` clause in use:

```

with MACHINE_CODE;

procedure INC ( N: in out INTEGER);

pragma CALL_SEQUENCE_PROCEDURE (
  INC,
  MECHANISM => (VALUE (R4) ),
  PRESERVED_REGISTERS => (R0, R1, R2, R3, R5, R6,
                          R7, R8, R9, R12, R13, R14 ));

procedure INC ( N: in out INTEGER) is
begin
  AISP_INST'(OPCODE => AISP,
             RA      => R4,
             N       => N1);

end INC;

```

XD Ada provides the pragma `CALL_SEQUENCE_PROCEDURE` which specifies parameter-passing mechanisms for machine code procedures. The pragma is defined in Appendix B. Examples of machine code insertion are given in Section 6.1 of the *XD Ada MIL-STD-1750A Run-Time Reference Manual*. For the specification of the package `MACHINE_CODE`, see Appendix D of the *XD Ada MIL-STD-1750A Run-Time Reference Manual*.

13.9 Interface to Other Languages

The following information supplements paragraph 4:

As with VAX Ada, use of pragma `INTERFACE` in XD Ada is interpreted as being equivalent to supplying the body of the named subprogram or subprograms. Therefore, the following rules apply:

- If a subprogram body is given later for a subprogram named with pragma `INTERFACE`, the body is illegal.
- If pragma `INTERFACE` names a subprogram body, the pragma is illegal.
- If a duplicate pragma `INTERFACE` is given, the latter pragma is illegal.

In XD Ada, pragma `INTERFACE` applies to a renaming only if the renaming occurs in the same declarative part or package specification as the pragma. The renamed subprogram must also occur in that same declarative part or package specification; renamed subprograms that occur outside the declarative part or package specification are ignored (without a warning diagnostic).

In addition, XD Ada interprets the effect of pragma INTERFACE in such a way that it accepts and ignores implicit declarations of subprograms (such as predefined operators, derived subprograms, attribute functions, and so on).

Dependent upon its use in an XD Ada program, pragma INTERFACE is interpreted in combination with one of two XD Ada import subprogram pragmas: IMPORT_FUNCTION or IMPORT_PROCEDURE. These pragmas are described in Section 13.9a.1.

The language name is ignored, and so may be any identifier that suggests the language, source, or nature of the imported subprogram.

If pragma INTERFACE is used without one of these import pragmas, a default interpretation is used, as follows:

- If the subprogram name applies to a single subprogram, then a default import pragma is assumed as follows:

For a function, the default is as follows:

```
pragma IMPORT_FUNCTION (function_designator);
```

For a procedure, the default is as follows:

```
pragma IMPORT_PROCEDURE (procedure_identifier);
```

- If the subprogram name applies to two or more subprograms, the pragma applies to all of them. However, a warning is given if the appropriate XD Ada import pragmas are not given for all of the subprograms.

Whether or not pragma INTERFACE is used with an import pragma, the subprogram name must be an identifier, or a string literal that denotes an operator symbol. In the following example, pragma INTERFACE specifies that the indicated routines SQRT and EXP are to be imported and used as bodies for the XD Ada functions SQRT and EXP in package FORT_LIB:

```
package FORT_LIB is
  function SQRT(X : FLOAT) return FLOAT;
  function EXP(X : FLOAT) return FLOAT;
private
  pragma INTERFACE(FORTRAN, SQRT);
  pragma INTERFACE(FORTRAN, EXP);
end FORT_LIB;
```

The following information supplements paragraph 5:

In XD Ada, the example package FORT_LIB is interpreted as follows: pragma INTERFACE specifies that the indicated routines SQRT and EXP are to be imported and used as bodies for the Ada functions SQRT and EXP in package FORT_LIB.

```
package CHOOSE_R is
  procedure P(X : INTEGER);
  procedure P(X : FLOAT);
private
  procedure R(X : FLOAT) renames P;
  pragma INTERFACE(ASSEMBLER, R);
end CHOOSE_R;
```

In this example, pragma INTERFACE indicates that the body for the second procedure P is to be imported as routine R.

The following information supplements the Notes section:

The meaning of the subprogram name is determined as for any name (see Section 8.3 (LRM)), except that the name can denote more than one subprogram. Thus, in the following declaration the pragma INTERFACE applies to the first two procedures; it does not apply to the third because the declaration is not visible at the place of the pragma.

```
procedure P (B: BOOLEAN);
procedure P (I: INTEGER);
pragma INTERFACE (ASSEMBLER, P);
procedure P (F: FLOAT);
```

This same interpretation is made for pragmas used to import and export subprograms (see Section 13.9a.1).

If pragma INTERFACE and pragma INLINE are used together, the pragma INLINE is ignored regardless of the order in which the two pragmas appear.

Refer to Chapter 3 of the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for subprogram calling conventions and run-time organisation, while Chapter 6 of the same manual describes low-level interfaces and assembly language modules.

13.9a XD Ada Import and Export Pragmas

XD Ada provides import and export pragmas designed specifically for constructing programs composed of both Ada and non-Ada entities. The import pragmas allow an Ada program to refer to entities written in another language; the export pragmas make Ada entities available to programs written in other languages. The names of the pragmas indicate the kind of entity involved: `IMPORT_FUNCTION` and `EXPORT_FUNCTION` apply to nongeneric functions; `IMPORT_PROCEDURE` and `EXPORT_PROCEDURE` apply to nongeneric procedures; `IMPORT_OBJECT` and `EXPORT_OBJECT` apply to objects; and `IMPORT_EXCEPTION` and `EXPORT_EXCEPTION` apply to exceptions. These pragmas are described in this section, summarized in Annex B, and listed in Appendix F.

All the XD Ada import and export pragmas have the following form:

```
pragma import_export_pragma_name
  (internal_name [, external_designator]
   [, pragma_specific_options]);

import_export_pragma_name ::=

  EXPORT_EXCEPTION | EXPORT_FUNCTION
  | EXPORT_OBJECT  | EXPORT_PROCEDURE
  | IMPORT_EXCEPTION | IMPORT_FUNCTION
  | IMPORT_OBJECT   | IMPORT_PROCEDURE

internal_name ::= [INTERNAL =>] simple_name
  | [INTERNAL =>] operator_symbol -- Can be used only for
                                -- IMPORT_FUNCTION

external_designator ::= [EXTERNAL =>] external_symbol

external_symbol ::= identifier | string_literal
```

The internal name can be an Ada simple name, or, if the declared entity is a function, the internal name can be a string literal that denotes an operator symbol. A subprogram to be imported or exported must be identified by its internal name and parameter types; and, in the case of a function, by the result type (see Section 13.9a.1.1).

The external designator determines a symbol that is referenced or declared in the linker object module. If an identifier is given, the identifier is used. If a string literal is given, the value of the string is used. The value of a string literal must be a symbol that is acceptable to the XD Ada Builder; it need not be valid as an Ada identifier. (For example, the dollar character (\$) can be used.) If no external designator is given, the internal name is used as the external designator. If the

external designator (explicit or default) is longer than 12 characters, the import or export pragma is ignored.

Pragma-specific options are described in the individual pragma sections that follow.

The XD Ada import and export pragmas are only allowed at the place of a declarative item, and must apply to an entity declared by an earlier declarative item of the same declarative part or package specification. At most one import or export pragma is allowed for any given entity; in the case of multiple overloaded subprograms, this rule applies to each subprogram independently.

Additional placement and usage rules apply for particular pragmas as described in the following sections.

Note:

Argument associations for XD Ada import and export pragmas can be either positional or named. With positional association, the arguments are interpreted in the order in which they appear in the syntax definition. The rules for the mixing of positional and named association are the same as those that apply to subprograms (see Section 6.4 (LRM)).

A pragma for an entity declared in a package specification must not be given in the package body. (A pragma for an entity given in the visible part of a package specification can, however, be given in either the visible or private part of the specification.)

No checking is provided to ensure that exported symbols do not conflict with each other or with other global symbols; such checking is performed by the XD Ada Builder.

13.9a.1 Importing and Exporting Subprograms

XD Ada provides a series of pragmas that make it possible to call nongeneric subprograms in a mixed-language programming environment. The `IMPORT_FUNCTION` and `IMPORT_PROCEDURE` pragmas specify that the body of the subprogram associated with an Ada subprogram specification is to be provided from assembly language. Pragma `INTERFACE` must precede one of these import pragmas (see Section 13.9). The `EXPORT_FUNCTION` and `EXPORT_PROCEDURE` pragmas allow an Ada procedure or function to be called from assembly language. The pragmas support parameter passing by means of registers.

13.9a.1.1 Importing Subprograms

XD Ada provides two pragmas for importing subprograms: `IMPORT_FUNCTION` and `IMPORT_PROCEDURE`. These pragmas allow the import of the kind of subprograms indicated.

The pragmas for importing subprograms have the following form:

```
pragma IMPORT_FUNCTION | IMPORT_PROCEDURE
(
  [ INTERNAL => ] internal_name
  [, [ EXTERNAL => ] external_designator ]
  [, [ PARAMETER_TYPES => ] ( parameter_types ) ]
  [, [ RESULT_TYPE => ] type_mark ]           -- FUNCTION only
  [, [ MECHANISM => ] mechanism ]
  [, [ RESULT_MECHANISM => ] mechanism_spec ] -- FUNCTION only
  [, [ FIRST_OPTIONAL_PARAMETER => ] FORMAL_NAME ]
  [, [ PRESERVED_REGISTERS => ] ( registers ) ]
);

parameter_types ::=
  null | type_mark (, type_mark)

mechanism ::=
  mechanism_spec | ( mechanism_spec (, mechanism_spec) )

mechanism_spec ::=
  mechanism_name [ ( [ REGISTER => ] register_name ) ]

mechanism_name ::=
  VALUE          |
  REFERENCE      | BIT_REFERENCE |
  DOPE_VECTOR    | BIT_DOPE_VECTOR

registers ::=
  null | register_name (, register_name )
```

Functions must be identified by their internal names and parameter and result types. The parameter and result types can be omitted only if there is exactly one function of that name in the same declarative part or package specification. Otherwise, both the parameter and result types must be specified.

Procedures must be identified by their internal names and parameter types. The parameter types can be omitted only if there is exactly one procedure of that name in the same declarative part or package specification. Otherwise, the parameter types must be specified.

The external designator denotes an XD Ada Builder global symbol that is associated with the external subprogram. If no external designator is given, the internal name is used as the global symbol.

The parameter types option specifies a series of one or more type marks (type or subtype names), not parameter names. Each type mark is positionally associated with a formal parameter in the subprogram's declaration. The absence of parameters must be indicated by the reserved word null.

The result type option is used only for functions; it specifies the type or subtype of the function result.

The mechanism option specifies how the imported subprogram expects its parameters to be passed (for example, by value, by reference or by descriptor). The calling program (namely the XD Ada program) is responsible for ensuring that parameters are passed in the form required by the external routine.

Mechanism names are described as follows. Within these definitions, the term *bit string* means any one-dimensional array of a discrete type whose components occupy successive single bits. The term *simple record type* means a record type that does not have a variant part and in which any constraint for each component and subcomponent is static. A *simple record subtype* is a simple record type or a static constrained subtype of a record type (with discriminants) in which any constraint for each component and subcomponent of the record type is static.

VALUE	Specifies that the immediate value of the actual parameter is passed. Values of scalars, access types, address types and private types whose full type is either a scalar, an access type or an address type can be passed by VALUE. If the value is a private type, the pragma must occur after the full declaration of the private type. Bit strings can also be passed by VALUE.
REFERENCE	Specifies that the address of the value of the actual parameter is passed. This mechanism can be used for parameters of any type.
DOPE_VECTOR	Specifies that the address of the DOPE_VECTOR is passed, a 32-bit pointer to an object, taking the form described in Section 2.1.4 of the XD Ada MIL-STD-1750A Run-Time Reference Manual.
BIT_DOPE_VECTOR	Specifies that the address of the BIT_DOPE_VECTOR is passed, a 32-bit pointer to an object, taking the form described in Section 2.1.4 of the XD Ada MIL-STD-1750A Run-Time Reference Manual.

If the first form of the mechanism option is given (a single mechanism name without parentheses), all parameters are passed using that mechanism. If the second form is given (a series of mechanism names in parentheses and separated by commas), each mechanism name determines how the parameter in the same position in the subprogram specification will be passed. With the second form, each parameter name must have an associated mechanism name.

The result mechanism option is used only for functions; it specifies the parameter-passing mechanism for passing the result type, and optionally, a specific register used to pass the result.

The preserved registers option gives a list of hardware registers which are not altered by the procedure or function. If this option is omitted it implies that no registers are preserved.

In addition to the rules given in Section 13.9a, the rules for importing subprograms are as follows:

- If an import pragma is given for a subprogram specification, pragma `INTERFACE` (see Section 13.9) must also be given for the subprogram earlier in the same declarative part or package specification. The use of pragma `INTERFACE` implies that a corresponding body is not given.
- If a subprogram has been declared as a compilation unit, the pragma is only allowed after the subprogram declaration and before any subsequent compilation unit.
- These pragmas can be used for subprograms declared with a renaming declaration. The internal name must be a simple name, and the renaming declaration must occur in the same declarative part or package specification as the pragma. The renamed subprogram must also occur in that same declarative part or package specification. Renamed subprograms that occur outside the declarative part or package specification are ignored (without a warning diagnostic).
- None of these pragmas can be used for a generic subprogram or a generic subprogram instantiation. In particular, they cannot be used for a subprogram that is declared by a generic instantiation of a predefined subprogram (such as `UNCHECKED_CONVERSION`).

Examples:

In this example, the pragma INTERFACE identifies SQRT as an external subprogram; the language name argument ASSEMBLER has no effect. The pragma IMPORT_FUNCTION uses positional notation to specify arguments for importing the declared function SQRT. The pragma form indicates that the internal name is SQRT, and the external designator is "MTH\$SQRT". The parameter is of type FLOAT, and is passed in R4; the result is of type FLOAT, and it is returned in R6.

```
function SQRT (X : FLOAT ) return FLOAT;
pragma INTERFACE (ASSEMBLER, SQRT);
pragma IMPORT_FUNCTION
    (SQRT, "MTH$SQRT", (FLOAT),
     FLOAT, (VALUE(R4)), VALUE(R6)
    );
```

The next example shows an alternative way of importing the declared function SQRT using named notation. In this case, the parameter is passed in R7, and the result is returned in R4; the registers which are preserved by the called function are also specified.

```
function SQRT (X : LONG_FLOAT ) return LONG_FLOAT;
pragma INTERFACE (ASSEMBLER, SQRT);
pragma IMPORT_FUNCTION (INTERNAL          => SQRT,
                        PARAMETER_TYPES   => (LONG_FLOAT),
                        RESULT_TYPE        => LONG_FLOAT,
                        MECHANISM          => (VALUE(R7)),
                        RESULT_MECHANISM   => VALUE(R4),
                        EXTERNAL           => "MTH$DSQRT",
                        PRESERVED_REGISTERS =>
                            (R0, R1, R2, R3, R12, R13, R14));
```

If the previous example is combined with the code in the first example (that is, with only one occurrence of pragma INTERFACE), the result is an overloading of SQRT:

```

function Sqrt (X : LONG_FLOAT ) return LONG_FLOAT;
function Sqrt (X : FLOAT ) return FLOAT;
pragma interface (ASSEMBLER, Sqrt);
pragma import_function (Sqrt,
                        "MTH$SQRT",
                        (FLOAT),
                        FLOAT,
                        (VALUE(R4)),
                        VALUE(R6));
pragma import_function (INTERNAL      => Sqrt,
                        PARAMETER_TYPES => (LONG_FLOAT),
                        RESULT_TYPE    => LONG_FLOAT,
                        MECHANISM       => (VALUE(R7)),
                        RESULT_MECHANISM => VALUE(R4),
                        EXTERNAL        => "MTH$DSQRT",
                        PRESERVED_REGISTERS =>
                        (R0, R1, R2, R3, R12, ^13, R14));

```

The next example shows the use of renaming with an imported procedure (it is assumed that these declarations occur in a declarative part or package specification). Note that the renaming causes the imported ASSEMBLER procedure to be used in calls to both procedures CHANGE and EXCHANGE. Also note that because no external designator is specified, the builder global symbol associated with the external subprogram is EXCHANGE, and because no parameter mechanisms are specified, the compiler's defaults will apply in calls to CHANGE or EXCHANGE.

```

procedure CHANGE (X,Y : INTEGER);
procedure EXCHANGE (X,Y : INTEGER) renames CHANGE;
pragma interface (ASSEMBLER, EXCHANGE);
pragma import_procedure (INTERNAL      => EXCHANGE,
                        PARAMETER_TYPES => (INTEGER, INTEGER));

```

13.9a.1.2 Exporting Subprograms

XD Ada provides two pragmas for exporting subprograms: EXPORT_FUNCTION and EXPORT_PROCEDURE. Both export pragmas establish an external name for a subprogram and make the name available to the XD Ada Builder as a global symbol, so that the subprogram can be called by in assembly language module.

The EXPORT_FUNCTION and EXPORT_PROCEDURE pragmas allow the export of the kind of subprograms indicated.

The pragmas for exporting subprograms have the following form:

```
pragma EXPORT_FUNCTION | EXPORT_PROCEDURE
( [ INTERNAL => ] internal_name
  [ , [EXTERNAL =>] external_designator ]
  [ , [PARAMETER_TYPES =>] ( parameter_types ) ]
  [ , [RESULT_TYPE =>] type_mark ]           -- FUNCTION only
  [ , [MECHANISM =>] mechanism ]
  [ , [RESULT_MECHANISM =>] mechanism_spec ] -- FUNCTION only
);

parameter_types ::=
  null | type_mark { , type_mark }

mechanism ::=
  mechanism_spec | ( mechanism_spec { , mechanism_spec } )

mechanism_spec ::=
  mechanism_name ( ( [REGISTER => ] register_name ) )

mechanism_name ::=
  VALUE          |
  REFERENCE      | BIT_REFERENCE  |
  DOPE_VECTOR    | BIT_DOPE_VECTOR

registers ::=
  null | register_name { , register_name }

parameter_types ::=
  null | type_mark { , type_mark }
```

Functions must be identified by their internal names and parameter and result types. The parameter and result types can be omitted only if there is exactly one function of that name in the same declarative part or package specification. Otherwise, both the parameter and result types must be specified.

Procedures must be identified by their internal names and parameter types. The parameter types can be omitted only if there is exactly one procedure of that name in the same declarative part or package specification. Otherwise, the parameter types must be specified.

The external designator denotes an XD Ada Builder global symbol that is associated with the external subprogram. If no external name is given, the internal name is used as the global symbol.

The parameter types option specifies a series of one or more type marks (type or subtype names), not parameter names. Each type mark is positionally associated with a formal parameter in the subprogram's declaration. The absence of parameters must be indicated by the reserved word null.

The result type option is used only for functions; it specifies the type or subtype of the function result.

The mechanism option specifies how the imported subprogram expects its parameters to be passed (for example, by value, by reference or by descriptor). The calling program (namely the XD Ada program) is responsible for ensuring that parameters are passed in the form required by the external routine. Mechanism options and possible values for mechanism names and class names are described in Section 13.9a.1.1.

If the first form of the mechanism option is given (a single mechanism name without parentheses), all parameters are passed using that mechanism. If the second form is given (a series of mechanism names in parentheses and separated by commas), each mechanism name determines how the parameter in the same position in the subprogram specification will be passed. With the second form, each parameter name must have an associated mechanism name.

The result mechanism option is used only for functions; it specifies the parameter-passing mechanism for passing the result type, and optionally, a specific register used to pass the result.

In addition to the rules given in Section 13.9a, the rules for exporting subprograms are as follows:

- An exported subprogram must be a library unit or be declared in the outermost declarative part of a library package. Thus, pragmas for exporting subprograms are allowed only in the following cases:
 - For a subprogram specification or a subprogram body that is a library unit
 - For a subprogram specification that is declared in the outermost declarations of a package specification or a package body that is a library unit
 - For a subprogram body that is declared in the outermost declarations of a package body that is a library unit

Consequently, an export pragma for a subprogram body is allowed only if either the body does not have a corresponding specification, or the specification and body occur in the same declarative part.

This set of rules implies that an `EXPORT_FUNCTION` or `EXPORT_PROCEDURE` pragma cannot be given for a generic library subprogram, nor can one be given for a subprogram declared in a generic library package. However, either of these pragmas can be given for a subprogram resulting from the instantiation of

a generic subprogram, provided that the instantiation otherwise satisfies this set of rules.

- In the case of a subprogram declared as a compilation unit, the pragma is only allowed after the subprogram declaration and before any subsequent compilation unit.
- Neither of these pragmas can be used for a subprogram that is declared with a renaming declaration.
- Neither of these pragmas can be used for a subprogram that is declared by a generic instantiation of a built-in library subprogram (such as UNCHECKED_CONVERSION).

Examples:

The following example shows an export pragma that causes the Ada procedure PROC to be exported for use in an assembly language module. The name PROC is declared as an XD Ada Builder global symbol.

```
procedure PROC (Y : INTEGER);
pragma EXPORT_PROCEDURE (PROC);
```

The next example shows an Ada function being called from an assembly language module:

```
function MULTIPLY (Y : in INTEGER) return INTEGER is
begin
    return Y * 10;
end;
pragma EXPORT_FUNCTION ( INTERNAL => MULTIPLY,
                        PARAMETER_TYPES => (INTEGER),
                        RESULT_TYPE    => INTEGER );
pragma CALL_SEQUENCE_FUNCTION (
    UNIT                => MULTIPLY,
    PARAMETER_TYPES     => (INTEGER),
    MECHANISM            => (VALUE(DO)),
    RESULT_MECHANISM    => VALUE(DO));
```

```

13.9a.2 Importing and Exporting Objects

XD Ada provides two pragmas for importing and exporting objects: `IMPORT_OBJECT` and `EXPORT_OBJECT`. The `IMPORT_OBJECT` pragma references storage declared in an assembly language module. The `EXPORT_OBJECT` pragma allows an assembly language module to refer to the storage allocated for an Ada object.

In addition to the rules given in Section 13.9a, the rules for importing and exporting objects are as follows:

- The object to be imported or exported must be a variable declared by an object declaration at the outermost level of a library package specification or body.
- The subtype indication of an object to be imported or exported must denote one of the following:
 - A scalar type or subtype.
 - An array subtype with static index constraints whose component size is static.
 - A record type or subtype that does not have a variant part and in which any constraint for each component and subcomponent is static (a simple record type or subtype).
- Import and export pragmas are not allowed for objects declared with a renaming declaration.
- Import and export pragmas for objects are not allowed in a generic unit.

Notes:

Objects of private or limited private types cannot be imported or exported outside the package that declares the (limited) private type. They can be imported or exported inside the body of the package where the type is declared (that is, where the full type is known).

The XD Ada pragmas for importing or exporting objects can precede or follow a pragma `VOLATILE` for the same objects (see Section 9.11).

Address clauses are not allowed in combination with any of the XD Ada pragmas for importing or exporting objects. If used in such cases, the pragma involved is ignored (see Section 13.5).

13.9a.2.1 Importing Objects

The XD Ada IMPORT_OBJECT pragma specifies that the storage allocated for the object (when the assembly language module is compiled) be made known to the calling Ada program by an externally-defined XD Ada Builder global symbol.

Pragma IMPORT_OBJECT has the following form:

```
pragma IMPORT_OBJECT
  (internal_name [, external_designator])
```

The internal name is the object identifier. The external designator denotes an XD Ada Builder global symbol that is associated with the external object. If no external designator is given, the internal name is used as the global symbol.

Because it is not created by an Ada elaboration, an imported object cannot have an initial value. Specifically, this restriction means that the object to be imported:

- Cannot be a constant (have an explicit initial value).
- Cannot be an access type (which has a default initial value of null).
- Cannot be a record type that has discriminants (which are always initialized) or components with default initial expressions.
- Cannot be an object of a task type.

Example:

```
PID: INTEGER;
pragma IMPORT_OBJECT (PID, "PROCESS$ID");
```

In this example, the variable PID refers to the externally-defined symbol PROCESS\$ID.

Alternatively, this example can be written in named notation as follows:

```
PID : INTEGER;
pragma IMPORT_OBJECT (INTERNAL => PID,
                     EXTERNAL => "PROCESS$ID");
```

13.9a.2.2 Exporting Objects

The XD Ada pragma `EXPORT_OBJECT` specifies that the storage allocated for the object (when the Ada program is compiled) be made known to assembly language modules by an XD Ada Builder global symbol.

Pragma `EXPORT_OBJECT` has the following form:

```
pragma EXPORT_OBJECT
  (internal_name [, external_designator])
```

The internal name is the object identifier. The external designator denotes an XD Ada Builder global symbol that is associated with the external object. If no external designator is given, the internal name is used as the global symbol.

Example:

```
PID: INTEGER;
pragma EXPORT_OBJECT (PID, "PROCESS$ID");
```

Alternatively, this example can be written in named notation:

```
PID: INTEGER;
pragma EXPORT_OBJECT (INTERNAL => PID,
  EXTERNAL => "PROCESS$ID");
```

13.9a.3 Importing and Exporting Exceptions

XD Ada provides the `IMPORT_EXCEPTION` and `EXPORT_EXCEPTION` pragmas for importing and exporting exceptions. The pragma `IMPORT_EXCEPTION` allows non-Ada exceptions to be used in Ada programs; the pragma `EXPORT_EXCEPTION` allows Ada exceptions to be used by foreign units.

The rules for importing and exporting exceptions are given in Section 13.9a.

Note:

A pragma for an exception that is declared in a package specification is not allowed in the package body.

13.9a.3.1 Importing Exceptions

The XD Ada `IMPORT_EXCEPTION` pragma is provided for compatibility with VAX Ada. This pragma specifies that the exception associated with an exception declaration in an Ada program be defined externally in non-Ada code.

In XD Ada pragma `IMPORT_EXCEPTION` has the following form:

```
pragma IMPORT_EXCEPTION
  (internal_name [, external_designator]
   [, [FORM =>] ADA ]);
```

The internal name must be an Ada identifier that denotes a declared exception. The external designator denotes an XD Ada Builder global symbol to be used to refer to the exception. If no external name is given, the internal name is used as the global symbol.

For compatibility with VAX Ada, the form option indicates that an Ada exception is being imported. If omitted, this defaults to ADA.

The external designator refers to an address that identifies the exception.

The VAX Ada version of this pragma supports an alternative form (VMS), and a code option in addition to the XD Ada arguments. If either of these unsupported arguments is specified, the compiler ignores the pragma and issues a warning message.

13.9a.3.2 Exporting Exceptions

The XD Ada `EXPORT_EXCEPTION` pragma allows Ada exceptions to be visible outside the XD Ada program, so that they can be raised and handled by programs written in XD Ada MIL-STD-1750A assembly language. This pragma establishes an external name for an Ada exception and makes the name available to the XD Ada Builder as a global symbol. Refer to the *XD Ada MIL-STD-1750A Run-Time Reference Manual* for further information on exporting exceptions.

Pragma `EXPORT_EXCEPTION` has the following form:

```
pragma EXPORT_EXCEPTION
  (internal_name [, external_designator]
   [, [FORM =>] ADA ]);
```

The internal name must be an Ada identifier that denotes a declared exception. The external designator denotes an XD Ada Builder global symbol to be used to refer to the exception.

The form option specifies that an Ada exception is being exported.

Example:

```
UNDERFLOW : exception
pragma EXPORT_EXCEPTION (UNDERFLOW, MTH_UNDERFLOW, ADA);
```

In this example, an Ada exception is exported as a global symbol.

13.10 Unchecked Programming

13.10.1 Unchecked Storage Deallocation

The following information supplements the Notes section:

Because UNCHECKED_DEALLOCATION is a predefined generic procedure, XD Ada does not allow the use of the IMPORT_PROCEDURE pragma to substitute an alternative procedure body.

13.10.2 Unchecked Type Conversions

The following information supplements paragraph 2:

XD Ada supports the generic function UNCHECKED_CONVERSION with the following restrictions on the class of types involved:

- The actual subtype corresponding to the formal type TARGET must not be an unconstrained array type.
- The actual subtype corresponding to the formal type TARGET must not be an unconstrained type with discriminants.

Further, when the target type is a type with discriminants, the value resulting from a call of the conversion function resulting from an instantiation of UNCHECKED_CONVERSION is checked to ensure that the discriminants satisfy the constraints of the actual subtype.

The effect with XD Ada is as if the source value is copied one word in ascending order of address, into the destination, also in ascending order of address. If the destination has fewer words than the source value, the high order words of the source value are ignored (truncated). If the source value has fewer words than the destination, the high order words of the destination are set to zero.

Representation Clauses and Implementation-Dependent Features

This chapter describes XD Ada MIL-STD-1750A Version 1.2 interrupt handling. In particular, it describes the handling of direct interrupt entries, and use of pragma `DIRECT_INTERRUPT_ENTRY`.

13.5.1 Interrupts

The following information supplements all of this section:

Unlike VAX Ada, XD Ada supports interrupts. The address in the `use` clause is the MIL-STD-1750A interrupt number.

In addition to support for normal Ada interrupt entries, XD Ada provides the additional pragmas `LEVEL` and `DIRECT_INTERRUPT_ENTRY`. Pragma `LEVEL` is given for a task type, or single task of anonymous type, and gives the level for its interrupts. Pragma `DIRECT_INTERRUPT_ENTRY` is used to connect an interrupt entry directly to the required interrupt vector, and is described below.

There are two ways an interrupt entry can be handled, according to whether or not the task has a pragma `LEVEL`. The *XD Ada MIL-STD-1750A Run-Time Reference Manual* gives examples of interrupt handlers.

Tasks with interrupt entries but no pragma LEVEL run at interrupt level 0 only while accepting an interrupt in a rendezvous. Other interrupts of the same level are inhibited while in the handler. When not accepting an interrupt, the task runs with all interrupts enabled. It is, however, possible to lose interrupts with this method.

Tasks with interrupt entries and a pragma LEVEL always run at interrupt level, whether inside or outside a rendezvous. This enables the user to avoid losing interrupts.

An interrupt entry to a task with the pragma LEVEL behaves like an ordinary entry call. An interrupt entry to a task with no pragma LEVEL behaves like a conditional entry call. If there is an accept statement waiting for the interrupt, the body of the accept statement is executed immediately. When the body is complete, the task is inserted in the ready queue and the interrupt completed by a return-from-interrupt instruction. The accept statement can call subprograms and make entry calls, but must not suspend the task before the interrupt is dismissed, otherwise the program repeatedly services the interrupt unsuccessfully.

Writing interrupt handlers in XD Ada requires detailed knowledge of the behavior of the target computer's interrupt system. It is not possible simply to place a use clause on an entry to achieve the desired effect.

Normal Ada interrupt entries cause a tasking reschedule each time an interrupt occurs. This inevitably incurs a performance overhead, and may mean that interrupts are not serviced quickly enough. In order to avoid this problem, XD Ada supplies pragma DIRECT_INTERRUPT_ENTRY, which causes the interrupt entry to be connected directly to the required interrupt vector. This run-time efficiency greatly improves response times. The form of this pragma is as follows:

```
pragma DIRECT_INTERRUPT_ENTRY(interrupt_entry);
```

Pragma DIRECT_INTERRUPT_ENTRY may be used where the program adheres to one of two supported code models. In fact, most applications will naturally adhere to one or other of the models, so the practical restrictions from this requirement are minimal. The use of pragma DIRECT_INTERRUPT_ENTRY must meet certain semantic conditions. These, along with the checks carried out by the compiler and run-time system, are described in full in the *XD Ada MIL-STD-1750A Run-Time Reference Manual* part of this manual.

Note that it is essential that the lowest level direct interrupt (or interrupt procedure) is always higher than the highest level normal interrupt, in order that the direct interrupt context is not left as a result of interruptive preemption.

The models and the related conditions are described in full, and examples of the models in use are given, in the *XD Ada MIL-STD-1750A Run-Time Reference Manual* part of this manual.

Interrupt procedures and Package INTERRUPT_SUPPORT are also described in the *XD Ada MIL-STD-1750A Run-Time Reference Manual* part of this manual.

Predefined Language Pragmas

In addition to the standard predefined pragmas, described in Annex B of the *Reference Manual for the Ada Programming Language*, XD Ada supports pragmas `CALL_SEQUENCE_FUNCTION`, `CALL_SEQUENCE_PROCEDURE`, `LINK_OPTION`, and `TITLE`, which are defined here. This annex also summarizes the definitions given elsewhere of the remaining implementation-defined pragmas.

Definitions

`CALL_SEQUENCE_FUNCTION`
`CALL_SEQUENCE_PROCEDURE`

The pragma `CALL_SEQUENCE_PROCEDURE` is used for describing machine code insertions or exported subprograms. It specifies how parameters are mapped onto registers, and which registers must be preserved, for machine code insertions (see Section 13.8). The pragma `CALL_SEQUENCE_FUNCTION` is also provided. These pragmas have the form:

```
pragma CALL_SEQUENCE_FUNCTION
(
  [ [UNIT =>] internal_name
  [, [RESULT_TYPE =>] type_mark ]
  [, [PARAMETER_TYPES =>] ( parameter_types ) ]
  [, [MECHANISM =>] mechanism ]
  [, [RESULT_MECHANISM =>] mechanism_spec ]
  [, [PRESERVED_REGISTERS => ] ( registers ) ]
);

pragma CALL_SEQUENCE_PROCEDURE
(
  [ [UNIT =>] internal_name
  [, [PARAMETER_TYPES =>] ( parameter_types ) ]
  [, [MECHANISM =>] mechanism ]
  [, [PRESERVED_REGISTERS => ] ( registers ) ]
);
```

```

parameter_types ::=
    null | type_mark (, type_mark)

mechanism ::=
    mechanism_spec | ( mechanism_spec {, mechanism_spec} )

mechanism_spec ::=
    mechanism_name [ ( {REGISTER => } register_name ) ]

mechanism_name ::=
    VALUE
    REFERENCE | BIT_REFERENCE
    DOPE_VECTOR | BIT_DOPE_VECTOR

registers ::=
    null | register_name (, register_name )

```

Functions must be identified by their internal names and parameter and result types. The parameter and result types can be omitted only if there is exactly one function of that name in the same declarative part or package specification. Otherwise, both the parameter and result types must be specified.

Procedures must be identified by their internal names and parameter types. The parameter types can be omitted only if there is exactly one procedure of that name in the same declarative part or package specification. Otherwise, the parameter types must be specified.

The parameter types option specifies a series of one or more type marks (type or subtype names), not parameter names. Each type mark is positionally associated with a formal parameter in the subprogram's declaration. The absence of parameters must be indicated by the reserved word null.

The result type option is used only for functions; it specifies the type or subtype of the function result.

The mechanism option specifies how the imported subprogram expects its parameters to be passed (for example, by value, by reference or by descriptor). The calling program (namely the XD Ada program) is responsible for ensuring that parameters are passed in the form required by the external routine.

If the first form of the mechanism option is given (a single mechanism name without parentheses), all parameters are passed using that mechanism. If the second form is given (a series of mechanism names in parentheses and separated by commas), each mechanism name determines how the parameter in the same position in the subprogram specification will be passed. With the second form, each parameter name must have an associated mechanism name.

The result mechanism option is used only for functions; it specifies the parameter-passing mechanism for passing the result type.

Mechanism names are described in Section 13.9a.1.1.

The preserved registers option gives a list of hardware registers which are not altered by the procedure or function. If this option is omitted it implies that no registers are preserved; in this case the effect is one of the following:

- If the body of the subprogram is written in Ada, the compiler calculates which registers are preserved
- If the body of the subprogram is a machine code insertion, the pragma has the same effect as pragma IMPORT_PROCEDURE

LINK_OPTION

This pragma is used to associate link option file names with a program. Link option files are used to specify the target and mapping definitions to be used when building the program. In this way, they do not have to be explicitly defined on the XDACS LINK command line. The appropriate external target and mapping definitions (in the form of link option files) are entered into the program library by use of the XDACS command COPY LINK_OPTION/FOREIGN, as described in *Developing XD Ada Programs on VMS Systems for the MIL-STD-1750A*. If a suitable link option file exists in another program library, it can be copied to the current program library with the XDACS command COPY LINK_OPTION. The advantage of using link option files is that the program definition is separate from the program itself, and so can be altered without making the last compile obsolete. The LINK_OPTION pragma therefore removes the need to recompile the whole program. More detail on this topic can be found in Sections 7.9 and 8.10 of *Developing XD Ada Programs on VMS Systems for the MIL-STD-1750A*.

Pragma LINK_OPTION has the form:

```
pragma LINK_OPTION (link-option-file-name
[,link-option-file-name]);

link-option-file-name :=
    [TARGET=>] target-option
    | [MAPPING=>] mapping-option
```

This pragma is only allowed in the outermost declarative part of a subprogram that is a library unit; at most one such pragma is allowed

in a subprogram. If it occurs in a subprogram other than the main program, this pragma has no effect (see Sections 9.8 and 9.9 (LRM)).

TITLE

Takes a title or a subtitle string, or both, in either order, as arguments. Pragma TITLE has the form:

```
pragma TITLE (titling-option
              [,titling-option]);

titling-option :=
    {TITLE =>} string_literal
  | {SUBTITLE =>} string_literal
```

This pragma is allowed anywhere a pragma is allowed; the given strings supersede the default title or subtitle portions of a compilation listing.

Summary

Pragma

EXPORT_EXCEPTION

Meaning

Takes an internal name denoting an exception, and optionally takes an external designator (the name of an XD Ada Builder global symbol), and a form (ADA) as arguments. This pragma is only allowed at the place of a declarative item, and must apply to an exception declared by an earlier declarative item of the same declarative part or package specification. The pragma permits an Ada exception to be handled by programs written in XD Ada MIL-STD-1750A assembly language (see Section 13.9a.3.2).

EXPORT_FUNCTION

Takes an internal name denoting a function, and optionally takes an external designator (the name of an XD Ada Builder global symbol), parameter types, and result type as arguments. This pragma is only allowed at the place of a declarative item, and must apply to a function declared by an earlier declarative item of the same declarative part or package specification. In

the case of a function declared as a compilation unit, the pragma is only allowed after the function declaration and before any subsequent compilation unit. This pragma is not allowed for a function declared with a renaming declaration, and is not allowed for a generic function (it can be given for a generic instantiation). This pragma permits an Ada function to be called from a program written in assembly language (see Section 13.9a.1.2).

EXPORT_OBJECT

Takes an internal name denoting an object, and optionally takes an external designator (the name of an XD Ada Builder global symbol), and size designator as arguments. This pragma is only allowed at the place of a declarative item at the outermost level of a library package specification or body, and must apply to a variable declared by an earlier declarative item of the same package specification or body; the variable must be of a type or subtype that has a constant size at compile time. This pragma is not allowed for objects declared with a renaming declaration, and is not allowed in a generic unit. This pragma permits an Ada object to be referred to by a routine written in assembly language (see Section 13.9a.2.2).

EXPORT_PROCEDURE

Takes an internal name denoting a procedure, and optionally takes an external designator (the name of an XD Ada Builder global symbol), and parameter types as arguments. This pragma is only allowed at the place of a declarative item, and must apply to a procedure declared by an earlier declarative item of the same declarative part or package specification. In the case of a procedure declared as a compilation unit, the pragma is only allowed after the procedure declaration and before any subsequent compilation

unit. This pragma is not allowed for a procedure declared with a renaming declaration, and is not allowed for a generic procedure (it may be given for a generic instantiation). This pragma permits an Ada routine to be called from a program written in assembly language (see Section 13.9a.1.2).

IMPORT_EXCEPTION

Takes an internal name denoting an exception, and optionally takes an external designator (the name of an XD Ada Builder global symbol), and a form (ADA) as arguments. This pragma is only allowed at the place of a declarative item, and must apply to an exception declared by an earlier declarative item of the same declarative part or package specification. The pragma is included for compatibility with VAX Ada (see Section 13.9a.3.1).

IMPORT_FUNCTION

Takes an internal name denoting a function, and optionally takes an external designator (the name of an XD Ada Builder global symbol), parameter types, and result type as arguments. Pragma **INTERFACE** must be used with this pragma (see Section 13.9). This pragma is only allowed at the place of a declarative item, and must apply to a function declared by an earlier declarative item of the same declarative part or package specification. In the case of a function declared as a compilation unit, the pragma is only allowed after the function declaration and before any subsequent compilation unit. This pragma is allowed for a function declared with a renaming declaration; it is not allowed for a generic function or a generic function instantiation. This pragma permits an assembly language routine to be used as an Ada function (see Section 13.9a.1.1).

IMPORT_OBJECT

Takes an internal name denoting an object, and optionally takes an external designator (the name of an XD Ada Builder global symbol), as arguments. This pragma is only allowed at the place of a declarative item at the outermost level of a library package specification or body, and must apply to a variable declared by an earlier declarative item of the same package specification or body; the variable must be of a type or subtype that has a constant size at compile time. This pragma is not allowed for objects declared with a renaming declaration, and is not allowed in a generic unit. This pragma permits storage declared in an assembly language routine to be referred to by an Ada program (see Section 13.9a.2.1).

IMPORT_PROCEDURE

Takes an internal name denoting a procedure, and optionally takes an external designator (the name of an XD Ada Builder global symbol), and parameter types as arguments. Pragma **INTERFACE** must be used with this pragma (see Section 13.9). This pragma is only allowed at the place of a declarative item, and must apply to a procedure declared by an earlier declarative item of the same declarative part or package specification. In the case of a procedure declared as a compilation unit, the pragma is only allowed after the procedure declaration and before any subsequent compilation unit. This pragma is allowed for a procedure declared with a renaming declaration; it is not allowed for a generic procedure or a generic procedure instantiation. This pragma permits an assembly language routine to be used as an Ada procedure (see Section 13.9a.1.1).

INTERFACE

In XD Ada, pragma **INTERFACE** is required in combination with pragmas **IMPORT_FUNCTION** and **IMPORT_PROCEDURE** (see Section 13.9a.1).

LEVEL

This pragma identifies a task or task type as running at interrupt level. Pragma **LEVEL** has one argument specifying the level for its interrupts (see Section 13.5.1).

STORAGE_UNIT

In XD Ada, the only argument allowed for this pragma is 16.

SUPPRESS_ALL

This pragma has no argument and is only allowed following a compilation unit. This pragma specifies that all run-time checks in the unit are suppressed (see Section 11.7).

VOLATILE

Takes the simple name of a variable as the single argument. This pragma is only allowed for a variable declared by an object declaration. The variable declaration and the pragma must both occur (in this order) immediately within the same declarative part or package specification. The pragma must appear before any occurrence of the name of the variable other than in an address clause or in one of the XD Ada pragmas **IMPORT_OBJECT** or **EXPORT_OBJECT**. The variable cannot be declared by a renaming declaration. The **VOLATILE** pragma specifies that the variable may be modified asynchronously. This pragma instructs the compiler to obtain the value of a variable from memory each time it is used (see Section 9.11).

Predefined Language Pragmas

This chapter supplies details of three pragmas introduced by XD Ada MIL-STD-1750A Version 1.2, pragma `DIRECT_INTERRUPT_ENTRY`, pragma `IDENT` and pragma `TIME_SLICE`. XD Ada pragmas in addition to those defined in Annex B of the *Reference Manual for the Ada Programming Language* (`CALL_SEQUENCE_FUNCTION`, `CALL_SEQUENCE_PROCEDURE`, `LEVEL`, `LINK_OPTION` and `TITLE`) are described in the *XD Ada MIL-STD-1750A Supplement to the Ada Language Reference Manual* for Version 1.0.

Definitions

IDENT

Takes a string literal of 31 or fewer characters as the single argument. The pragma `IDENT` has the following form:

```
pragma IDENT (string_literal);
```

This pragma is allowed only in the outermost declarative part of a compilation unit. The given string is used to identify the object module associated with the compilation unit in which the pragma `IDENT` occurs.

Summary

Pragma	Meaning
<code>DIRECT_INTERRUPT_ENTRY</code>	Takes the simple name of an interrupt entry, which must have no parameters, as the single argument. This pragma signals to the compiler that the interrupt

TIME_SLICE

entry is to be directly connected to the hardware interrupt (see Section 13.5.1).

Takes a static expression of the predefined fixed point type **DURATION** (in Package **STANDARD**) as the single argument. This pragma is only allowed in the outermost declarative part of a library subprogram, and at most one such pragma is allowed in a library subprogram. It has an effect only when the subprogram to which it applies is used as a main program. This pragma specifies the nominal amount of elapsed time permitted for the execution of a task when other tasks of the same priority are also eligible for execution. A positive, nonzero value of the static expression enables scheduling for all tasks in the subprogram; a negative or zero value disables it (see Section 9.8a).
