PREFACE

The field investigation reported herein was conducted by the US Army Engineer Waterways Experiment Station (WES), Vicksburg, MS, during the period 2 to 7 November 1990 to provide the necessary data for support of the US Army Engineer Division, New England (NED), Boston Harbor Channel Improvement Project, Boston, MA. This effort was funded by NED, and liaison was maintained by Mr. Charles Wener of NED's Hydraulics and Water Quality Branch.

Personnel of the WES Hydraulics Laboratory (HL) Estuarine Processes Branch (EPB) performed the work under the general supervision of Messrs. Frank A. Herrmann, Jr., Chief, HL; Richard A. Sager, Assistant Chief, HL; William H. McAnally, Jr., Chief, Estuaries Division (ED); and George M. Fisackerly, Chief, EPB. The data collection program was designed by Messrs. Fisackerly and Timothy L. Fagerburg, EPB. Data reduction was performed by Ms. Clara J. Coleman and Messrs. Fagerburg and Joseph W. Parman, EPB. This report was prepared by Messrs. Fagerburg and Fisackerly and Ms. Coleman.

COL Larry B. Fulton, EN, was the Commander and Director of WES during the field investigation and data analysis. Dr. Robert W. Whalin was the Technical Director.

FIELD DATA COLLECTION REPORT
BOSTON HARBOR PROJECT, MASSACHUSETTS

PART I: INTRODUCTION

Background

1. The Port of Boston is located on the western side of Massachusetts Bay approximately 50 nautical miles* northwest of the tip of Cape Cod (Figure 1). It is the largest port in New England, its water area covering approximately 47 square miles, and is one of the United States oldest and most historic international trading centers. A source of jobs and commerce for the 13 million residents of the six-State New England region, the port annually handles about 21 million tons of cargo worth more than \$7 billion. Of the tonnages handled in 1988 approximately 88 percent was liquid petroleum products and the remaining 12 percent was non-petroleum bulk, containerized, and non-bulk cargo.

2. The US Army Corps of Engineers has constructed navigation channels in Boston Harbor. Deepwater access from the Atlantic Ocean is provided by three entrance channels: the Broad Sound North Channel with two lanes at depths of 35 and 40 ft below mean low water (mlw);** the 30-ft-deep Broad Sound South Channel; and the 27-ft-deep Narrows Channel. The entrance channels converge in the naturally deep President Roads area where there is an anchorage of approximately 350 acres. Other deep-draft navigation projects serve facilities presently based along the Main Ship Channel and three major tributaries. The Main Ship Channel extends from President Roads to the interior of the harbor and has two lanes with depths of 35 and 40 ft. Each lane is 600 ft wide. The three major tributary channels are the Reserved Channel, the Mystic River, and the Chelsea River. The Reserved Channel is 1 mile long and 430 ft wide. The Mystic River Channel is 6500 ft long and varies in width from 580 to 1060 ft. The Chelsea River Channel is 2 miles long and varies in

* A table of factors for converting non-SI units of measurement to SI (metric) units is found on page 3.

** All depths and elevations (el) described in this report refer to local mean low water (mlw), which is 2.75 ft below National Geodetic Vertical Datum (NGVD).

width from 225 to 430 ft. All the tributary channels have been improved to a depth of 35 ft. Some problems associated with vessel navigation within the existing projects are related to the limited available channel depths. The existing 35-ft-channel depth in the three tributary channels requires the larger vessels to load light and wait in the bay anchorage for favorable tides, resulting in costly delays and fewer ships calling on the port. To remedy the problem, the following modifications have been proposed:

- a. Deepen the Mystic River Channel to 40 ft mlw.
- b. Deepen the Chelsea River Channel to 38 ft mlw.
- c. Deepen the Reserved Channel to 40 ft mlw.

Purpose

3. The purpose of the Boston Harbor field monitoring program was to provide synoptic data collection of water-level elevations (tides) as well as current speed and direction measurements at various stations throughout the system. The purpose of this report is to provide a permanent record of the instrumentation and techniques employed during the data collection survey and to make the data available for use in long-term numerical modeling studies and ship simulation studies.

Scope

4. This report presents representative results of the field data collection program in the Boston Harbor project during November 1990. Measurements consisted of the following:

- a. Water-level elevations at six locations.
- b. Current speed and direction at twelve ranges.

5. This report describes the field investigation methods used to collect the data, displays the results of the data reduction efforts, and summarizes the results of the data analysis.

PART II: DATA COLLECTION PROGRAM

6. Data were collected in the Boston Harbor study area from 2 to 7 November 1990. Water levels were recorded throughout the period. An intensive data collection program (a 14-hr survey conducted on 5 November 1990) was performed with the deployment of water-level recorders. During this intensive 14-hr data collection period current speed and direction measurements were obtained concurrently with the water-level elevation measurements. The data collection effort is described in subsequent sections of this report.

Water-Level Elevations and Temperatures

Water-level recorders

7. The water-level measurements in the study area were recorded using Microtide (solid state measurement) water-level recorders similar to the one shown in Figure 2. The Microtide water-level recorders contain a strain-gage-type pressure transducer housed in a subsurface case which records the absolute pressure of the column of water above the case. The pressure transducer

Figure 2. Microtide water-level recorder

is not vented to the atmosphere; therefore, an extra unit is required to be strategically positioned in the study area to record atmospheric pressure changes. The water column pressure is measured for the desired sample interval, and an average value is computed and stored on the internal RAM data logger. The stated accuracy is ± 0.1 percent of full scale (25 psia). The sampling time interval can be set from 1 min to 24 hr. A 10-min sampling interval was chosen for this study.

Water temperature sensors

8. The Microtide water-level recorder also measures temperature by means of a YSI thermilinear thermistor built into the recorder. The thermistor has a range of -5°C to $+45^{\circ}\text{C}$, with a stated accuracy of $\pm 0.1^{\circ}\text{C}$. The data from each recorder are stored on an accessible RAM located in the waterproof subsurface unit which also contains the d-c power supply.

Measurement locations

9. Six water-level recorders were deployed throughout the study area as shown in Figure 3. Their locations are identified as S1.0, S2.0, S2.8, S5.8, S9.5, and S12.5. The locations were chosen for the strategic placement in Boston Harbor proper, the President Roads area, the Mystic River, and the Chelsea River, and the availability of a mounting structure. The locations adequately covered the total study area to provide information on phasing and amplitude of the peak tides during the data collection period.

Current Speed and Direction

Equipment setup

10. Six boats were equipped to deploy survey instruments over-the-side using the portable equipment setup shown in Figure 4. Collapsible aluminum frames were used to support the equipment, and winches (with 1/8-in. wire rope) were used to raise and lower the velocity and direction equipment. An indicator on the winch displayed the depth of the instruments below the water surface. A Gurley Model 665 vertical-axis cup-type impeller velocity meter with direct velocity read-out capabilities was used to measure the current speeds. These meters have a threshold speed of less than 0.2 fps and an accuracy of ± 0.1 fps for velocities less than 1 fps. Current directions were monitored with a magnetic directional indicator mounted above the velocity meter on a solid suspension bar. This entire assembly was connected to a

Boston Inner Harbor Nautical Chart No. 13272,
published by National Ocean Service 1981, US
Department of Commerce.

Figure 3 Instrument and data collection ranges location map

Figure 4. Field deployment of velocity measuring equipment

streamlined lead weight that held the sensors in a vertical position and oriented them into the direction of the flow. The signal cables from each instrument were raised and lowered with the equipment and were connected to the display units located on the deck of the boat. A more detailed display of the system is shown in Figure 5.

Figure 5. Components of the field instrument assembly

Measurement locations

11. For the 14-hr data collection period in the Boston Harbor study area, twelve ranges were selected to yield the information most applicable to the purpose. The general locations of these ranges are shown in Figure 3. Range R1.0, located in the President Roads area near Deer Island Entrance Light, had two stations equally spaced across the channel, Stations R1.0A and R1.0B, respectively. Range R2.0, located at the Long Island Bridge, had three stations equally spaced across the range, Stations R2.0A, R2.0B, and R2.0C. Range R3.0, located near the south-southwest end of Logan International Airport, had four stations, R3.0A, R3.0B, R3.0C, and R3.0D. Stations R3.0B and R3.0C were located at each edge of the channel. Range R4.0 was located immediately below the mouth of the Fort Point Channel. A centerline station only was used at this range, Station R4.0B. Range R5.0 was located approximately 0.2 mile south of the Boston Coast Guard Base. Range R6.0 was located in the entrance to the Constitution Marina. Range R7.0 was located approximately 0.1 mile south of the Little Mystic Channel. Range R8.0 was located in the Mystic River approximately 0.1 mile northwest of the Mystic River-Tobin Memorial Bridge. Range R9.0 was also located in the Mystic River approximately 0.3 mile east of the Malden-Bascule Bridge. Range R10.0 was located in the Chelsea River approximately 0.2 mile east of the Bascule Bridge near the confluence of the Mystic and Chelsea Rivers. Range R11.0 was located near the second Bascule Bridge on the Chelsea River. Range R12.0 was also in the Chelsea River approximately 0.5 mile northeast of the second Bascule Bridge. Ranges R4.0-R12.0 each had only one station located at the channel centerline.

Procedures

12. Prior to the beginning of the survey, the boats assigned to each range deployed anchors and mooring lines at each of the stations. The mooring lines were attached to large inflated buoys for retrieving the lines during each sampling period. The boat moved into position at each of the buoys and used the anchored line to hold a steady position in the current. The boat propellers were not turning while the data were being collected. At each station, current speed and direction were measured at five depths: near-bottom, three-quarter depth, middepth, one-quarter depth, and near-surface for each hour of the survey period. The near-bottom measurements were made at a distance of 2.0 ft from the actual bottom. The three-quarter, middepth, and one-quarter measurements were obtained at the actual fractional depth

measurement. The near-surface measurements were obtained at a distance of 3.0 ft below the water surface.

Conditions

13. The 14-hr intensive data collection period encompassed an entire tide cycle during a spring tide range. The maximum tidal range measured during the survey was 13.3 ft. Mostly clear skies existed at the time of the survey, and wind conditions ranged from a light wind of 4 to 5 mph to a stiff northeast wind of 12 mph.

Post-Survey Procedures

14. On 7 November 1990, following the intensive data collection survey, the water-level recorders were serviced to retrieve the collected data. Then the data were transferred to computer diskettes using an RS232 communication cable and a portable computer. Physical measurements from the water surface to established reference points for determination of depth of submergence of the sensor were made for verification of sensor readings prior to the removal of each sensor.

PART III: DATA PRESENTATION

Water-Level Elevation Data

15. The tidal variations of the water-level elevation data observed during the intensive survey are listed in Tables 1-5. Plots of the water-level data for periods of 24 hr prior to, during, and following the survey period dates are shown in Plates 1-5. All the water-level recorders, with the exception of S1.0, functioned properly during the period immediately prior to and following the survey. Instrument locations S1.0 and S2.0 each had two water-level recorders installed for backup purposes in the event one of the instruments failed to record the data. An unusual situation occurred at location S1.0 where both of the recorders failed to record any data. Just prior to installation, the gages had been prepared to set the start time of the data recording and to verify that the sensor was operating properly. At location S2.0 both instruments worked properly. At all other locations only a single water-level recorder was deployed.

16. The data from S2.0 were used as reference data for comparison with the data from the other stations in order to estimate tidal phase and range differences between the lower portion of Boston Harbor and the upper boundaries of the study area. This comparison illustrated that tide ranges observed were essentially equal with the maximum tidal range observed at S2.0 and S9.5 of 13.2 ft on 5 November 1990. The comparison also demonstrated the tide phase difference was 0.17 hr between S2.0, S9.5, and S12.5 occurring on 5 November 1990 at the time of high water. During the ebb phase period, the time lag between the low water reading at the gage at S9.5 (at 1850 EST) and the gage at S2.0 (1840 EST) was also 0.17 hr.

Over-the-Side Current Speed and Direction Data

17. Tables 6-23 are time series listings of the over-the-side current speed data obtained at the twelve ranges as described in paragraph 11. Plates 7-23 are plots of the velocity data for each range for the cycle of the tide (ebb and flood) during the survey period. The maximum velocity observed at the lower range, at Station R1.0A, in the channel was 4.0 fps at the surface during the flood cycle. The maximum velocity observed in the Mystic

River channel at Station R8.0B was 1.4 fps at the one-quarter depth during the ebb cycle. The maximum velocity in the channel of the Chelsea River at Station R12.0B was 1.4 fps at the surface during the ebb cycle.

18. The freshwater inflow from the rivers local to this area did not contribute significantly to the flow in the channel as is indicated by the generally low velocity readings obtained at Ranges R8.0 to R12.0. As a result, there were no large variations, other than tidal, in the magnitude and direction of the currents. No eddies and unusual flow circulation patterns created by change in the tidal periods were observed, other than those presented in the data. However, the changes within the system were not always detectable using hourly observation periods representative of this study.

PART IV: SUMMARY

19. The following observations were made of the data presented herein which were collected from the intensive survey and longer term sampling efforts within the Boston Harbor system from 2 to 7 November 1990:

- a. The tide ranges were virtually the same from the lower harbor water-level recorder, S2.0, to the upper Chelsea River water-level recorder, S12.0.
- b. The time lag between the peak water levels of the lower bay and upper river was approximately 0.17 hr.
- c. The maximum velocities observed during the survey occurred at the strength of flood of the tidal cycle. The maximum recorded velocity was 4.0 fps at Station R1.0A.
