SUMMARY

This project was designed to develop antiviral agents by adapting new enzymatic and pharmacokinetic principles to inhibition of the HIV-reverse transcriptase. Towards this end synthetic organic procedures were directed to synthesis of compounds in the following categories.

1. 3' Nucleosidee spiroxiranes and a series of related compounds having the potential to function as suicide inhibitor of the reverse transcriptase through the 3' functionality.
2. A series of sterol phosphonoformate analogs designed to improve delivery of the active phosphonoformate (PFA) moiety to sites of viral replication.
3. A series of 5' sterol ester derivatives of azido thymidine designed to improve the pharmacokinetics and blood half life of AZT.

Synthetic compounds were tested for antiviral activity against HIV and EIAV in tissue culture, against purified HIV-reverse transcriptase in enzyme kinetic studies, where appropriate and samples of synthetic analogs were supplied to the US Army Antiviral Program for screening against a battery of 10 viruses of interest as military disease hazards.

In addition to the targeted objectives, the serendipitous observation of a cell product that enhances the sensitivity of HIV-reverse transcriptase towards inhibtion by Foscarnet (PFA) by almost 1000 fold, was explored further resulting in preliminary identification of the sensitizing compound.

The major accomplishments in the categories listed above are summarized below and are described in more detail in the appropriate sections of the final report.

Organic synthetic procedures for the synthesis of a new class of compounds, the 3' nucleoside sproxiranes were developed. A series of these and related compounds and intermediates modified at the 2' and 3' functionalities were tested for activity against HIV and EIAV in tissue culture. Six compounds showing promising antiretroviral activity were identified. Several additional compounds were identified in the subsequent USAMRID screeing tests is being active against additional viruses including Punta, Toro, Vaccinia, and Yellow Fever.

A procedure for synthesis of sterol esters of phosphonoformate (FOSCARNET) was developed by

condensation of cholesterol chloroformate with the appropirate dialkylphosphite. Several of these compounds displayed greater antiviral activity than the parent compound PFA and side chains that enhanced (or detracted) from the activity were identified.

Three 5' cholesterol ester derivatives of AZT were synthesized and showed antiviral activity in tissue culture demonstrating that the cholesterol ester hydrolases of the cell could liberate the active moiety intracellularly. The ^{3}H radiolabelled AZT derivative of cholesterol sebacate was synthesized and used to evaluate blood and tissue half life of the ^{3}H-AZT moiety in mice. Administration of AZT as the sterol ester derivative inproved the blood half life of AZT by over 100 fold (< 1/2 hr to > 48 hr) and was accompanied by significant accumulation in tissues including brain.

The interaction of the effective antiviral compound 3' uridine sproxirane and the recombinant HIV reverse transcriptase enzyme was investigated in depth in order to characterize the suicide inhibition native of the interaction. This compound was designed as a potential suicide inhibitor of reverse transcriptase through the oxirane functionality at the 3' position. This compound showed good antiviral activity against HIV in cell culture and also against a second retrovirus (Equine Infectious Anemia).

In order to determine if the observed antiviral activity was due (as predicted) to inhibition of reverse transcriptase, the kinetic properties of 3' uridine spiroxirane were evaluated against the purified recombinant HIV-reverse transcriptase in vitro. In order to do this the triphosphate derivative of the nucleoside analog (the true putative inhibitor) was synthesized using a newly developed procedures for synthesizing nucleoside triphosphates.

It was found that the 3' uridine spiroxirane triphosphate derivative was an effective inhibitor of the HIV reverse transcriptase in the 0.1 to 1 micromolar range. The time course of the inhibition was progressive as expected for a suicide type inhibitor. Furthermore, the inhibition was not reversed by addition of excess template thus distinguishing it from a simple chain-terminating inhibitor and confirming that the inhibition resulted in the progressive and permanent inactivation of the enzyme characteristic of a suicide inhibitor. Thus it is concluded that the antiviral activity of the spiroxirane analogs we have synthesized is indeed related to their ability to function as suicide susbstrates for the HIV reverse transcriptase.

The compounds synthesized and supplied to USAMRID for antiviral testing are tabulated. The test data

indicating I_{c50}, cytotoxicity and therapeutic index for all compounds showing antiviral activity are summarized on the Appendix to this final report.

The project was thus characterized by an unexpectedly high degree of success.

Of a total of 4a compounds synthesized and supplied to USAMRID for antiviral testing a total of 9 proved to have effective activity against one or more viruses of interest as military disease hazards including HIV, Punta, Toro, Vaccinia, and Yellow Fever. These compounds and the viruses against which they are effective are listed on the final page of this report. Futhermore, most of these showed low cytotoxicity in cell culture assays suggesting that they will be potentially useful therpeutic agents if future in vivo testing is ever carried out. Finally, the basic enzyme kinetic studies carried out in the extended (unfunded) 4th year of the contract, support the basic idea underlying these investigations, in that effective antiviral agents can be developed based upon the principle of suicide inhibition of key viral enzymes.

A. INTRODUCTION

Retroviruses are characterized by the anomalous storage of their genetic information in th form of RNA. They are a diverse group of organisms which have been shown to be causative agen in a number of mammalian and avian diseases states Lentiviruses are a subfamily o retroviruses which have been linked to the induction of arthritis, encephalitis, and slow neurologic diseases in certain species. Many of these viruses are characterized by their ability to develop nov antigenic variants that can escape temporarily from host immune surveillance Interest i retroviruses in human disease states has increased with the isolation of HTLV I and II as the causativ agents of adult human T cell leukemias and of HIV I and II as the cause of Acquired Immun Deficiency Syndrome (AIDS)

The most recent evaluation of the AIDS epidemic in the U.S. indicates that the curren total of approximately 70,000 AIDS cases is accompanied by a further 1 to 1.5 million infecte individuals, the majority of whom will progress to the clinically overt disease state in the next 5- years. In the near-term absence of an effective vaccine an increase in this infected/symptomle category is likely to continue for a number of years.

In addition to an antiviral therapy for acute cases of AIDS therefore, there is clearly pressin need for an effective antiviral drug regimen suitable for administration to large numbers of otherwi healthy individuals in order to arrest progression of the disease. By preventing viral replication, suc therapy may also reduce dissemination of the virus and thus indirectly fulfill some of the immedia functions of a vaccine. The current drug of choice, AZT can have undesirable side effects when use at maximum therapeutic dosages over prolonged periods. In addition HIV-variants with increase resistance to AZT have recently begun to appear. Combination therapy with drugs having a differe mechanism of action can reduce the likelyhood that resistant variants will appear. The drugs beir developed in this project are designed with the above potential for use in long-term combinatic therapy low of toxicity as a primary goal.

Replication of retroviruses is critically dependent upon a single enzyme called reve transcriptase (RT). This is an RNA-dependent DNA polymerase first found in the purified virio of Rous sarcoma virus by Temin and murine leukemia virus by Baltimore The enzym transcribes the viral RNA into DNA in the first step of viral replication. Since host cells do n contain reverse transcriptase, several molecules of the enzyme are packaged in each virion and ent the cell together with the viral RNA. It is at this stage that viral replication is most sensitive inhibitors of the reverse transcriptase, before amplification of the viral genome and pol gene directe synthesis of endogenous RT has taken place.

The principle that inhibitors of reverse transcriptase will inhibit replication of retrovirus is well established. For example, 3'-azido-3' deoxythymidine, the triphosphate of which inhibits th RT activity of HIV, is a potent inhibitor of virus replication in cultured H-9 cells in the rage of 1 10 micromolar and is being used successfully in patients with AIDS. Prolonged administratio may cause serious side effects. Another agent which has shown promise is phosphonoformate (PFA Foscarnet) which inhibits the RT activity of with an I_{50} of only 0.1 micromolar. However, muc higher concentrations of up to 340 micromolar are required for complete inhibition of HI replication in H-9 cells Other drugs including the dideoxycytidines which are also based upo inhibition of RT by chain termination of the viral template are in clinical trial. Since none of thes drugs permanently inactivate the reverse transcriptase and since they do not accumulate intracellularly in significant amounts, virus replication will resume when blood levels of the drug decrease.

Since there is no complete animal model for HIV which reproduces the immunodeficiency, as an adjunct to the tissue culture studies thisproject will also utilize the Rauscher murine leukemia virus which has a reverse transcriptase with close homology to that of HIV, for in vivo testing of new antiviral drugs. This will be supplemented by testing drug toxicity in human T lymphocytes growing in tissue culture.

Suicide Inhibitors of Reverse Transcriptase

Suicide inhibitors, also known as Kcat inhibitors, are active site directed substrate analogs which contain a latent, reactive group. Following cleavage of the analog by the target enzyme the reactive group is released at the active site and inactivates the enzyme Inhibitors of this type have several potential therapeutic advantages int that they can be designed to be highly specific for

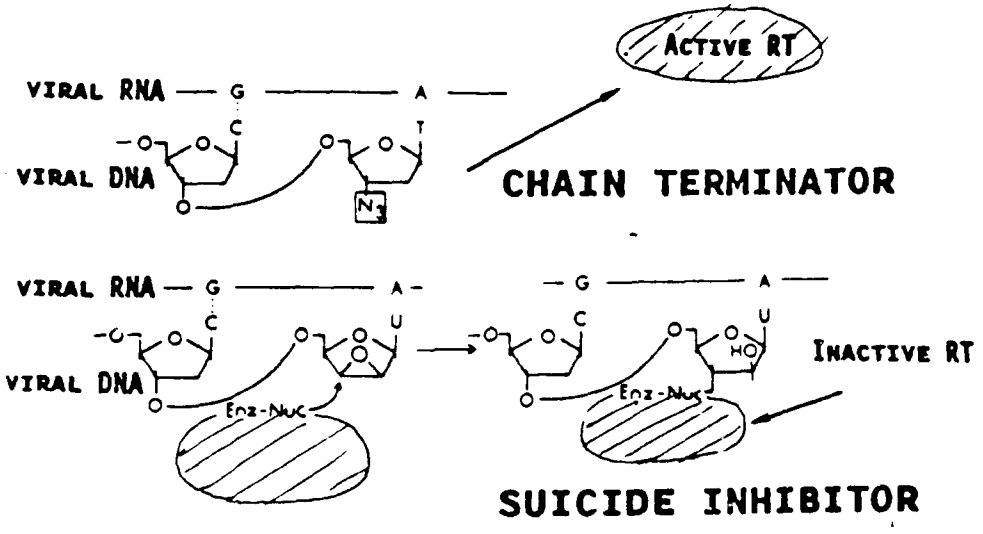
the target enzyme. Since most normal cells do not contain active or functional reverse transcriptases this reduces the possibility of side effects. Furthermore, by their nature, inhibitors of this type remain metabolically inert unless specifically cleaved by the target enzyme. Finally, the inhibition is permanent and irreversible, so that viral replication will not resume when the blood levels of the drug decrease. This feature could be particularly useful in long-term therapy of chronic human retrovirus infection.

Inhibition of retroviral replication by 3'-Nucleoside Spiroxirane Derivatives:

An apparent suicide inhibitor of E.Coli DNA polymerase was described by Abboud et al. It was shown that adenosine 2'3'-riboepoxide 5'-triphosphate irreversibly inactivated the enzyme by a covalent interaction. Because of the intrinsic reactivity of the epoxides however they are not suited for use under physiological conditions. We will therefore synthesize a series of nucleoside 3'-spiroxirane analogs. These are designed to inhibit the enzyme by an analogous suicide mechanism and are based upon the observation that the uridine 3'-ribospiroxirane derivative is an inhibitor of retroviral replication in cultured cells and selectively suppresses reverse transcriptase production by the VCF 21 (Moss) vaccinia HIV-RT recombinant. Furthermore at therapeutic levels it has no significant effects on ^{3}H-thymidine incorporation in cultured T-lymphocytes.

In the first step of replication of viral DNA by reverse transcriptase, activation of the primer 3'-OH by the enzyme results in incorporation of the suicide nucleotide by a normal 3',5'-phosphodiester linkage. At this point the inhibition resembles a simple chain termination similar to that produced by other 3'-blocked nucleoside analogs such as 3'-azidothymidine (AZT) and dideoxycytidine. However when the next step in the elongation reaction is attempted, the enzyme by activating the 3'-oxygen of the spiroxirane functionality becomes alkylated by the substrate and effectively commits suicide. A primary objective of these studies will be to characterize the kinetics of inhibition of the purified HIV-reverse transcriptase by the nucleoside spiroxirane triphosphates to determine if this second suicide step occurs and contributes to the observed antiviral activity of these compounds. Initial indications that the analogs can accomplish irreversible inactivation of intracellular RT support this possibility, and further efforts will be made to incorporate features into the molecule which favor the suicide pathway.

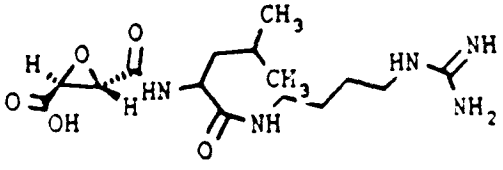
Because of the greater stability of the oxirane ring under physiological conditions these analogs offer several advantages over the simple epoxide types: A schematic representation of the consequences of an interaction with a suicide inhibitor versus a chain terminator is given below.



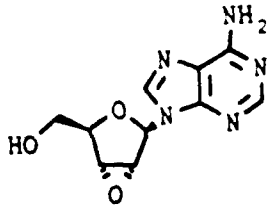
B. WORK ACCOMPLISHED

Epoxide Suicide Inhibitors:

Epoxide-containing irreversible (suicide) inhibitors have been reported for a number enzymes, the structures of two such compounds are shown below. One of the first, [N-(L-3-*tran* carboxyxiran-2-carbonyl)-L-leucyl]-amido (4-guanido) butane was isolated from *Aspergill japonicus* and was found to irreversibly inhibit cysteine proteases by alkylation of the sulfydr group at the active site.

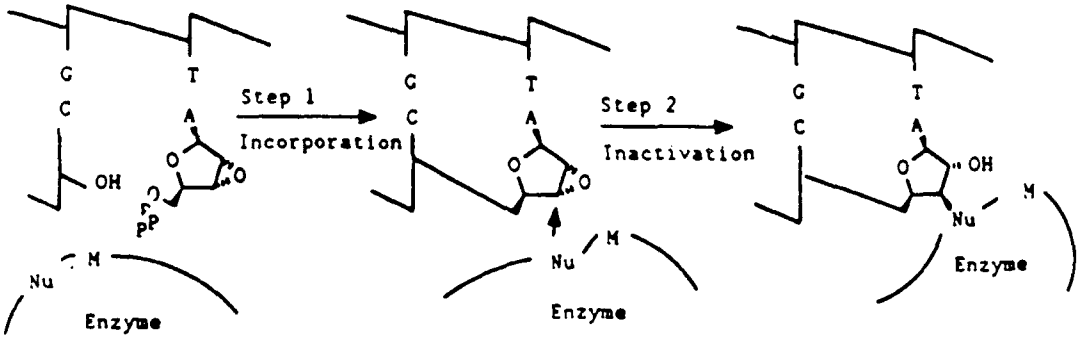


[N-(L-3-*trans*-carpoxioxiran-2-carbonyl) -L-leucyl]-amido(4-guanido)butane



9-(2,3-Anhydro-β-D-ribofuranosyl)adenine

A 2',3'-riboepoxynucleoside, 9-(2,3-anhydro-β-D-ribofuranosyl)adenine, was shown, as the 5' triphosphate, to irreversibly inhibit avian myeloblastosis virus DNA polymerase (a revers transcriptase) Its mechanism of inactivation, shown below, is believed to involve alkylation c the enzyme in the active site upon activation of the epoxide ring after incorporation of the nucleosid to the end of the growing DNA strand

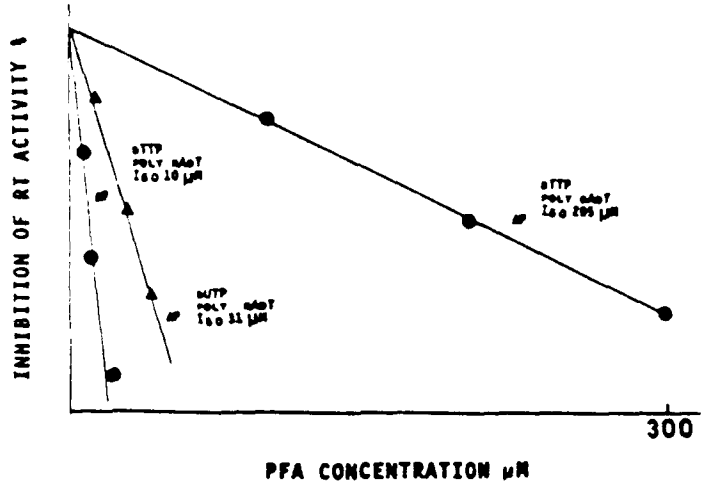


A proposed mechanism for RT inactivation by 2',3'-riboepoxyadenosine.

A similar compound, 1-(2,3-anhydro-β-D-lyxofuranosyl)cytidine, was recently synthesized by Broder et. al. and was found to inhibit HIV *in vitro* Although the mechanism of inactivation was not elucidated, irreversible inactivation was considered a possibility. We have also synthesized the corresponding 1-(2,3-anhydro-β-D-lyxofuranosyl) uridine and found it to have antiviral activity. However these epoxide derivatives unlike the spiroxiranes (see below) are also cytotoxic at higher concentrations probably owing to the greater reactivity of the epoxide ring

Preliminary Synthetic and Antiviral Screening Studies:

The reverse transcriptase of HIV is a highly error prone enzyme, a factor which probably contributes to the high mutation rate of the HIV genome. We have shown that reverse transcriptase readily incorporates dUTP in place of dTTP when transcribing from a poly rAdT template, and this incorporation, like that of dTTP, is particularly sensitive to inhibition by PFA (figure).



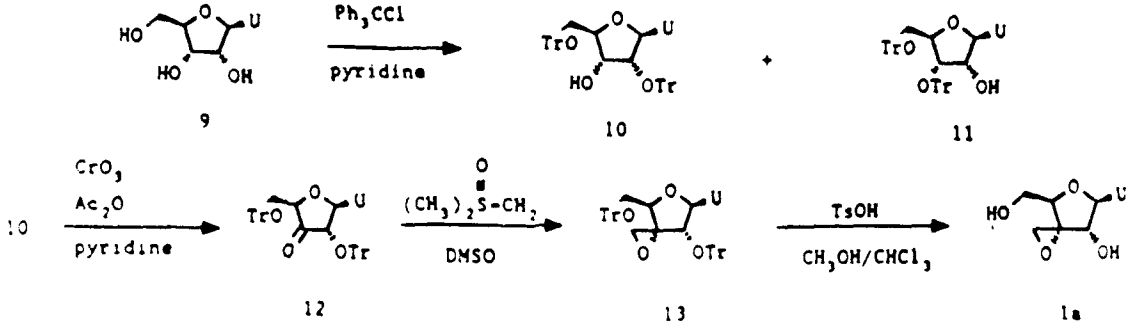
Reverse Transcriptase catalyzed Incorporation of d-UTP: Differential Inhibition of First-strand Synthesis by Foscarnet.

Since uridine is an unnatural base for the cellular DNA polymerases, initial studies were carried out using uridine nucleosides to enhance the antiviral selectivity.

Synthesis of Uridine 2' and 3'-Ribospiroxiranes:

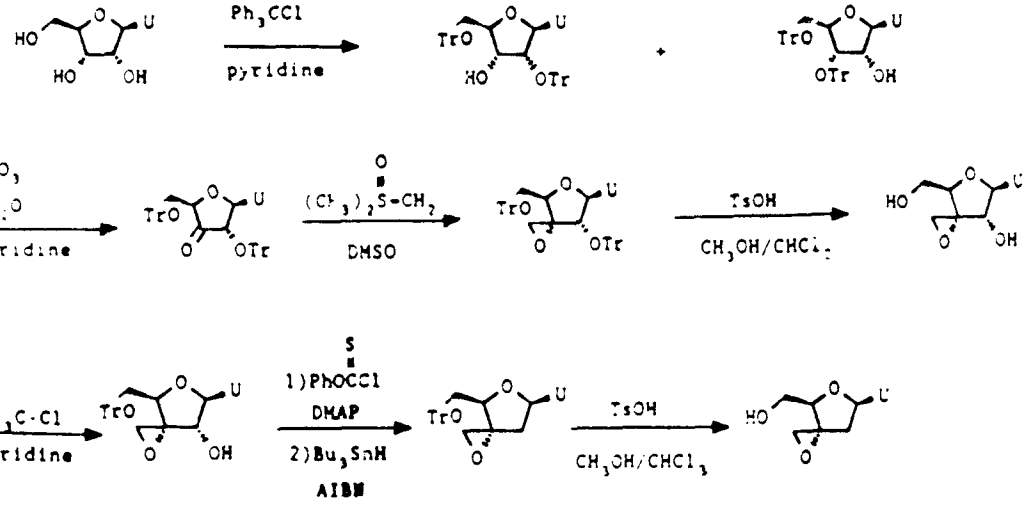
3'-uridine spiroxirane was synthesized from uridine by the sequence of reactions shown below. The procedure begins with the selective tritylation of uridine by the procedure of Cook and Moffat (38). Chromatographic separation of the isomers yielded the 2'5'and 3'5'-di-O-trityluridines in good yield. The 2',5'isomer was oxidized with chromium trioxide in pyridine/acetic anhydride to 3',5'-di-O-trityl 3'-ketouridine. Treatment of this compound with two equivalents of dimethyloxosulfonium methylide yielded the 2',5'-di-O-trityl spiroxirane derivative which upon mild acid catalyzed hydrolysis yielded the deprotected 3'-uridine spiroxirane.

The corresponding 2'-spiroxirane derivative was also prepared from the 2',3'-di-O-trityl isomer by analagous procedures and characterized by IR and NMR spectroscopy.



Synthesis of Spiroxirane Nucleosides:

This will be carried out by the general procedures used for synthesis of the uridine 3'-ibospiroxirane described in section C above. The further extension of this to the synthesis of the 2'-piroxiranes from the 3'5'-di-O-trityl isomers and the 3'-dideoxy spiroxiranes from the 5'-mono-O-trityl derivative is summarized in the scheme below.



This route to the deoxynucleoside spiroxiranes is preferred since direct conversion of the orresponding deoxynucleosides by procedures analagous to steps 1-3 in the above scheme may lead o base elimination following conversion to the 3'-keto derivative . Since trityl ethers of primary lcohols are more readily hydrolyzed than those of secondary alcohols it is not possible to obtain the '-mono-trityl uridine spiroxirane directly from the 3',5' derivative, which must first be completely eprotected and converted by the procedure of Michelson and Todd . Free radical deoxygenation f C-2 by the procedure of Acton et al via the 2'-O-phenylthiocarbonate followed by eprotection of the 5'-hydroxyl group yields the desired 2'-deoxy-3'-spiroxirane. The absolute onfigurations of the 3' and 2' uridine spiroxiranes obtained by this synthesis have not yet been ssigned. However it has been reported by Corey and Chaykousky , that dimethyloxo-sulfonium nethylide affords spiroepoxides with an equatorial methylene in reaction with 4 t-butyl yclohexanone, which would lead to spiroxiranes having the ribo-configurations illustrated. piroxiranes in the alternative lyxo configuration however may also be obtained by this general rocedure by reaction of the 3'-ketoderivatives with dimethyl sulfonium methylide, as illustrated n the scheme below. In contrast to dimethyloxosulfonium methylide, this reagent yields piroexpoxides with an axially oriented methylene

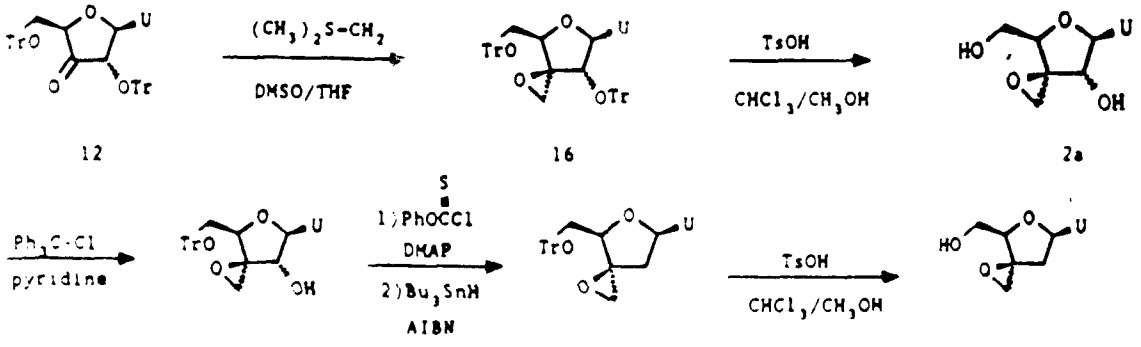


Fig.

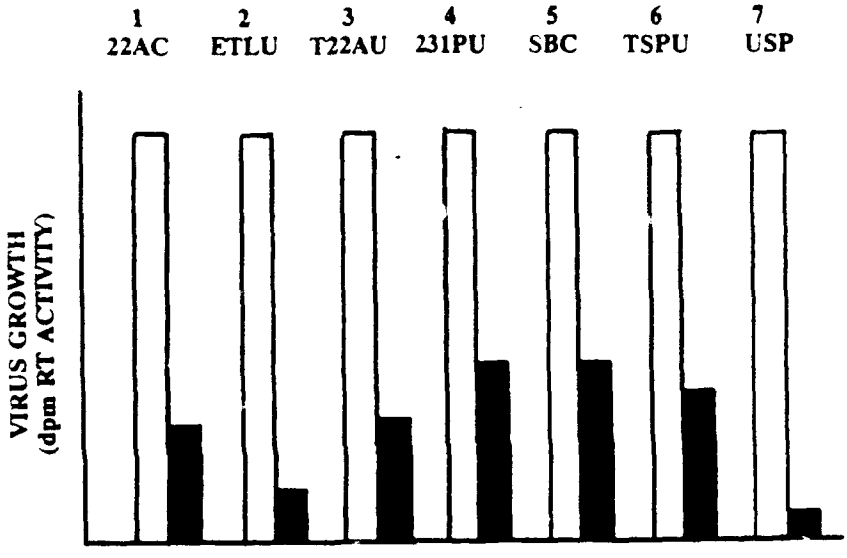
Antiviral Activity of Uridine Spiroxiranes and Cytotoxicity Screening in Human T-Lymphocytes:

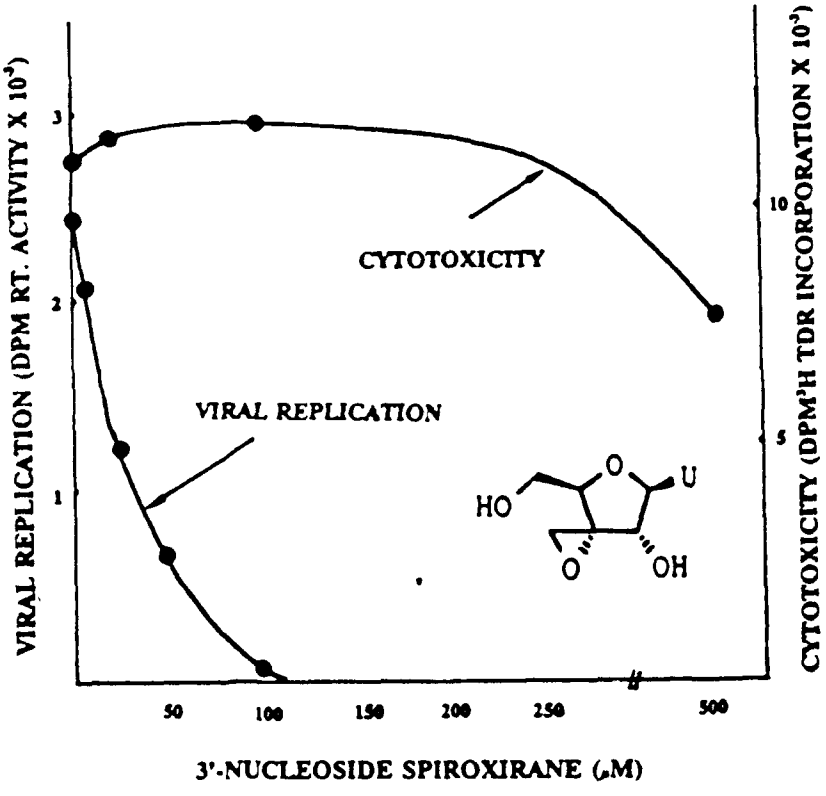
A series of approximately 30 nucleoside analogs, suggested by the considerations outlined in section B, were synthesized. These were screened for ability to inhibit replication of equine infectious anemia virus growing in equine derma. fibroblasts. This is a lentivirus having a close homology with HIV and is non pathogenic to humans. It is used as a preliminary screen for antiviral drugs before testing against HIV grown in A 3.01 human T-lymphocytes as described in section D. Cytotoxicity was evaluated at concentrations from 25-500μM in IL-2 supplemented CTLL T-Lymphocyte cultures pulsed with ^{3}H thymidine at 24 and 48 hours.



Antiviral Activity of Some Epoxy- and Oxirane Nucleosides:

Viral replication was monitored by RT assay on the pelletized virions from the culture medium. As illustrated in the figure above, 7 of these compounds inhibited viral replication by greater than 50% when present in the culture medium at a concentration of 100μM. The two most effective analogs were the uridine 2', 3'-lyxo epoxide (compound 2) and the uridine 3'-ribospiroxirane (compound 7). Both compounds were also tested for cytotoxicity by measuring their effects on ^{3}H-thymidine incorporation in the IL-2 dependent CTLL T-lymphocyte cell line in tissue culture.

The 3'-uridine spiroxirane derivative was added to control and EIAV infected cultures over a range of concentrations from 5 to 100μM and reverse transcriptase activity was assayed on the pelletized virions after 8 days. Virus replication was almost completely inhibited by 100μM concentrations of the 3' uridine spiroxirane the I_{50} being about 25μM. The corresponding 2'-spiroxirane used as a control had no effect at similar concentrations. The 3'-spiroxirane was non-toxic to T-lymphocytes,the I_{50} for inhibiting ^{3}H-thymidine incorporation being greater than 500μM. Since the epoxide derivative was somewhat inhibitory to T-cell proliferation at concentrations above 100μM, whereas the spiroxirane analog was not, the nucleoside spiroxirane family has been selected for further in depth characterization in this project.



Antiviral Activity of Uridine 3'-ribospiroxirane.

Cultures of equine dermal cells were infected with a standard inoculum of the EIAV retrovirus in the presence of increasing concentrations of uridine 3' spiroxirane. Virus replication was measured by following release of reverse transcriptase into the culture medium. In separate experiments growth inhibition of cultured T lymphocytes was evaluated by measuring incorporation of tritiated thymidine (TdR) into cellular DNA. Note the greater sensitivity of the viral versus the cellular polymerases presumably due to the ability of the cellular polymerases to "proofread" and excise the unusual nucleoside.

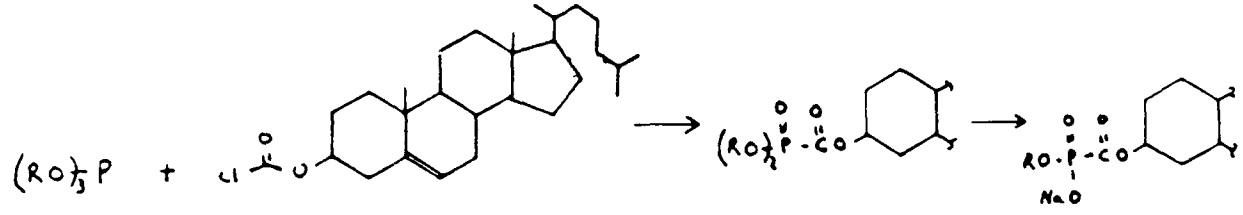
Antiviral Properties of the Sterol Phosphonoformates

Despite the sensitivity of the HIV-RT to inhibition by PFA, replication of the virus in tissue cultu is relatively insensitive, the I_{50} being of the order of 50 μM.

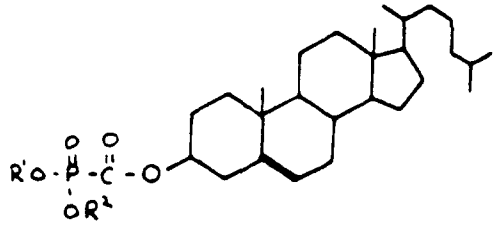
We have shown in previous studies, by use of sterol ester analogs such as the sterically hindered a hydrolysis resistant cholesterol $\alpha\alpha$-methyl ethyl caproate (CMEC), that intact cholesterol esters enter ce via a specific endocytotic transport process To enhance deliverability of the active PFA moiety to endosomal sites of viral replication, cholesteryl phosphonoformate ester analogs of PFA have be synthesized and characterized.

Cholesteryloxycarbonylphosphonoformates:

A series of mono- and di-alkyl cholesteryloxycarbonylphosphonoformates have been successfu prepared via an Arbozov reaction between trialkylphosphites and cholesterylchloroformate.



Triesters gave acceptable spectroscopic characteristics and were selectively hydrolyzed to the mon and di-sodium salts



Properties of Some Sterol Phosphonoformates.

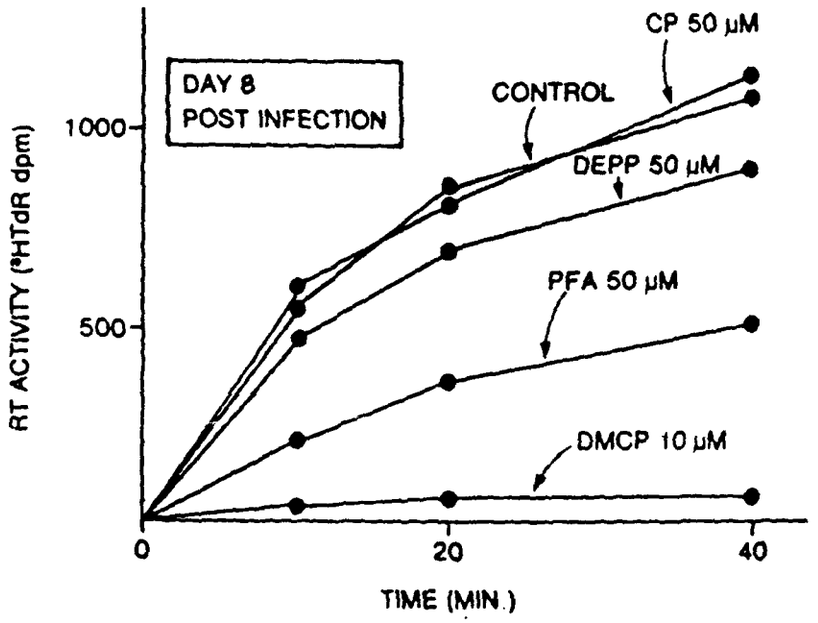
° Solvent systems: A, 50% ethyl acetate/hexanes, B, 20% ethyl acetate/hexanes, C, 52/14/1/1 $CHCl_3/CH_3OH$/con NH_4OH/H_2O.

A number of compounds of this type having both aromatic and aliphatic substituents have been test for antiviral activity in vitro, as detailed below. Incorporation of the sterol moiety in an appropriate triesi environment can result in compounds having 20-30 times the antiviral potency of the parent compound PF Table lists the effect of increasing the number and size of the R groups on the melting point a chromatographic mobilities of some of these derivatives.

Pending development of the low biohazard CPE assay for HIV infectivity described below, t antiviral potency of the drugs was evaluated against Equine Infectious Anemia Virus (EIAV) growing in fe equine fibroblasts. This is a lentivirus with a reverse transcriptase having the highest degree of homolo with HIV-1 RT. The assay consists in measurements of RT activity on pelletized supernatants of infect cultures 8 days following infection. These sterol esters of phosphonoformate show an interesting pattern antiviral activity in this system

ANTI-VIRAL ACTIVITY OF SOME STEROL PHOSPHONOFORMATES



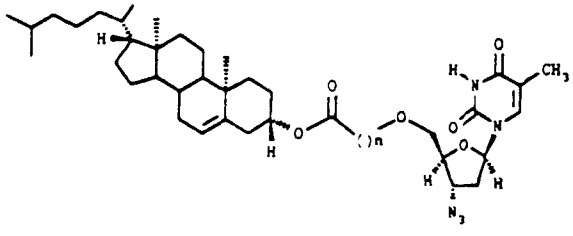
The approximate I_{50} for inhibition of EIAV replication by PFA is between 40 and 50 µM. The liethyl-phenyl-phosphonoformate ester (DEPP) is only about 20% as active as PFA and the doubly charged lisodium cholesterol phosphonoformate (CP) is essentially inactive. Substitution of the phenyl group with : cholesterol group, however, results in a major enhancement of activity. For example, the closely related)MCP (lower curve, in which cholesterol is esterified to the formate moiety, has 10-20 times more nti-viral activity than the parent compound PFA. Some of the more active analogs display activities close o the theoretical maximum predicted by the enzyme kinetic studies.

The sterol phosphonoformates display another useful property since the antiviral effects persist fc a considerable time (up to 8 days) after removal of the drug from the culture medium. It seems likely th this prolonged antiviral protection may be due to intracellular accumulation of the analog followed by slo hydrolysis and sustained release of the active PFA moiety. One of the objectives in this Project is to explo this observation in more depth by measuring rates of intracellular accumulation and hydrolysis of ster phosphonoformates using ^{14}C-labelled compounds synthesized by analagous procedures. In this way ligan which enhance uptake can be distinguished from those which enhance (or reduce) hydrolysis. Th information will be used to enhance pharmacokinetic properties which may prove clinically useful.

SYNTHESIS AND ANTIVIRAL ACTIVITY OF AZT-STEROL DICARBOXYLATES:

^{3}H-labelled AZT was prepared by $NaB^{3}H_{4}$ reduction of the 5'aldehyde derivative and coupled cholesterol by a C_{10} (Sebacate) linker as described in section D, to yield cholesteryl sebacyl ^{3}H-AZT (CSE AZT). Unlabelled cholesteryl succinyl AZT (CS-AZT) and cholesteryl carbonate AZT (CCAZT) having tl structures illustrated below, were also synthesized

STRUCTURES OF SOME SYNTHETIC AZT STEROL DIESTERS



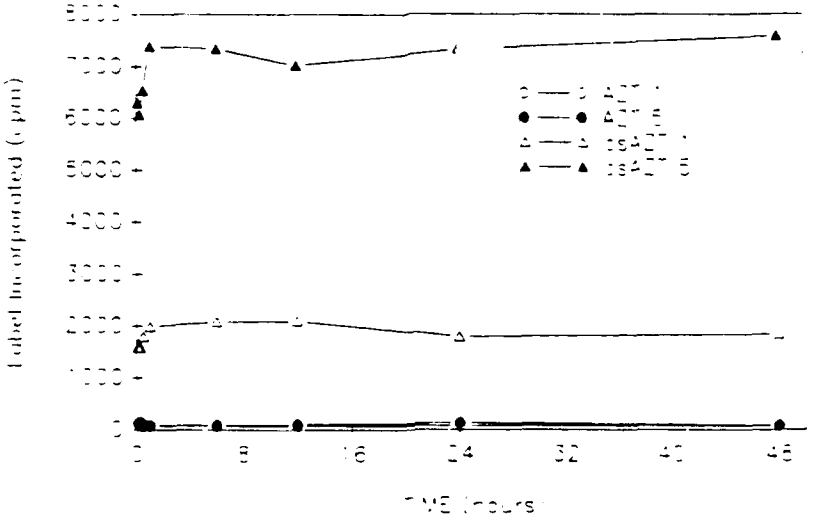
n = 0 Cholesterol Carbonate AZT (CC-AZT)

n = -CH2CH2 Cholesterol Succinate AZT (CSc-AZT)

n = -(CH2)8 Cholesterol Sebacylate AZT (CSb-AZT)

The uptake and accumulation of the ^{3}H-labelled AZT sterol sebacylate was compared with that c ^{3}H-AZT in the human T-lymphocyte cell line over a 48 hr period at two concentrations (1 μM and 5 μM in the medium. Cells were harvested at intervals and washed using a Mash harvester before countin Maximum accumulation and rentention (following the wash procedure) occured within 1 hour and w approximately 15 and 80 fold greater for the sterol derivatives than for free AZT at the two concentratior (1μM and 5μM) respectively

ENHANCED ACCUMULATION OF RADIOLABELLED CSB - AZT IN T LYMPHOCYTES



The unlabelled AZT-sterol dicarboxylates showed good antiviral activity at similar concentratio as measured by suppression of viral RT levels in culture supernatants Figure suggesting that the prodru were being hydrolyzed intracellularly to the free form. Use of the radiolabelled analogs to explore facto regulating this intracellular accumulation and release will be a major objective of the further studies propose in this project.

SYNTHESIS OF NUCLEOSIDE TRIPHOSPHATE ANALOGS FOR ANTIVIRAL TESTING:

The classical procedures for synthesis of nucleotide triphosphates require relatively large quantities of the nucleoside precursor and frequently give poor yields.

Ludwig and Eckstein (J. Org. Chem. 1989, 54,631-635) have reported an approach involving condensation of an activated nucleoside derivative with inorganic pyrophosphate. In this synthesis 2-chloro-4H-1,3,20-benzodioxaphosphorin-4-one phosphitylates the 5'-hydroxy group of a nucleoside to form an intermediate 2, which on subsequent reaction with pyrophosphate produces a nucleosidylcyclotriphosphite 3. This intermediate is oxidized with iodine/water to furnish nucleoside 5'-triphosphate. The procedure is suitable for use with low milligram quantities.

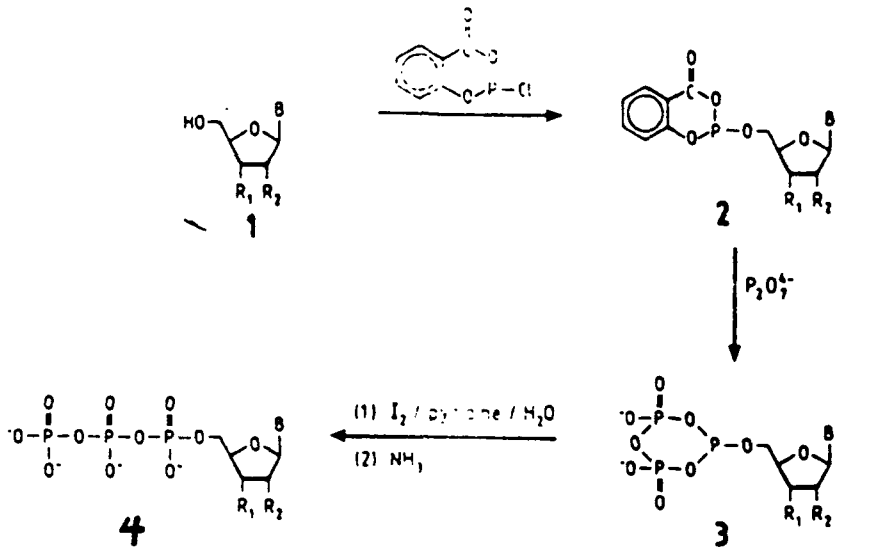
The series of reactions illustrated in Scheme I was successfully applied to microscale preparations of the 5'-triphosphates of both AZT and 3' uridine spiroxirane 1a which was previously synthesized and shown to have antiviral activity.

The formation of intermediate 3 was detected by ^{31}P NMR spectroscopy. The observed chemical shifts are comparable to those reported in the literature. The spectrum is of the ABX type where the AB part corresponds to the two phosphate groups with close but not identical shifts and the X part corresponds to the trivalent phosphorous atom. Oxidation of the intermediate 3 yields the normal triphosphate. In the ^{31}P NMR spectrum, the triplet of the trivalent phosphorous atom of the intermediate compound 3 disappears indicating complete oxidation.

We suspected some nucleotide by-products due to the contamination by a small amount of triphosphate. Also hydrolysis of intermediate 2 could result in phosphorous containing contamination detected by ^{31}P NMR. These by-products must copurify with the unreacted nucleoside on DEAE-cellulose chromatography.

The antiviral activity of the synthesized AZTTP was tested and proved comparable to, and in some cases even more effective than, a sample provided by the Burroughs Wellcome Co., thus validating the procedure. The nucleoside spiroxirane triphosphate may exist in two different isomeric forms which may or may not have identical antiviral activity. We have isolated one isomer that has proved antiviral activity. Isolation and characterization of the other isomer requires further investigation. The validated procedure was then applied to synthesize the 5' triphosphate of 3' uridine spiroxirane.

Scheme I



The phosphitylating agent 2-chloro-4H-1,3,2-benzodioxaphosphorin-4-one was purchased from Aldrich. Dimethylformamide (DMF) was dried over $MgSO_4$ and distilled under reduced pressure. Anhydrous dioxane was distilled from LAH. Anhydrous pyridine was prepared by fractional distillation of refluxing pyridine with potassium hydroxide.

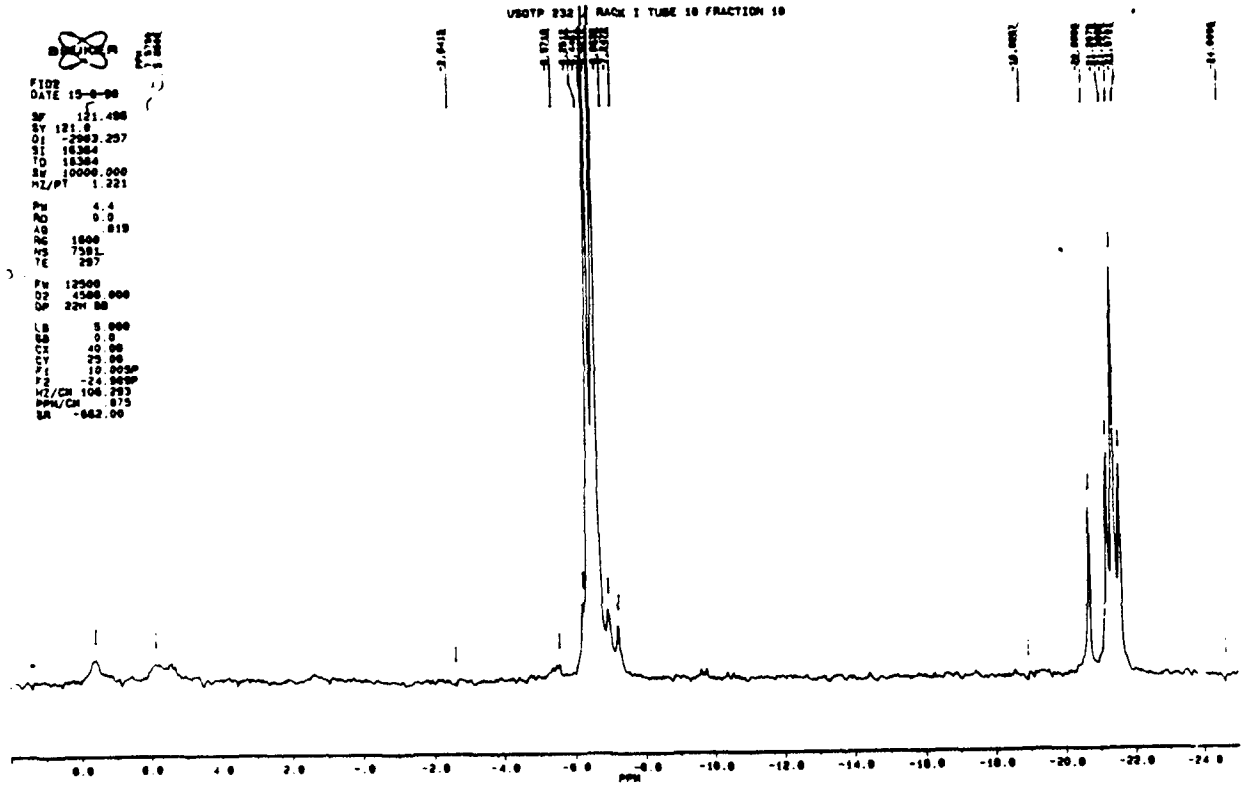
^{31}P NMR spectra were recorded on a Brucker 300 spectrometer with broad band decoupling. TLC was performed on either silica GHLF (Analtech) developed with isopropanol, ammonia, water (3:1:1) (system 1) or on DEAE-cellulose (Analtech) developed with 0.02 N hydrochloric acid (system 2).

Bis(tri-n-butylammonium) pyrophosphate. Tetrasodium diphosphate decahydrate (2.23 g, 5 mmol) was dissolves in water (50 ml), the solution was applied to a column of Dowex 50WXB in the H^+ form and the column was washed with water. The eluate was directly dropped into a cooled (ice water) and stirred solution of tri-n-butylamine (2.38 ml, 10 mmol) in ethanol (20 ml). The column was washed until the pH of the eluate increased to 5.0 (approximately 70 ml of water). The ethanol/water solution was evaporated to dryness and reevaporated twice with ethanol and finally with anhydrous DMF and diluted to 10 ml. This solution was stored over 4-Å molecular sieves.

Nucleoside spiroxirane 1a (100 μmol) was dissolved in anhydrous pyridine/DMF, 1/4, V/V and evaporated to dryness in vacuo. The residue was dried further over P_2O_5 under reduced pressure for 2 hours at room temperature. The reaction flask was filled with nitrogen, during all the following manipulations a small positive pressure of nitrogen was maintained in the reaction vessel. Anhydrous pyridine (200 μl) and DMF (800

μl) were injected through septum. A freshly prepared 1 M solution of 2-chloro-4H-1.3.2-benzodioxaphosphorin-4-one in anhydrous dioxane (110 μl, 110 μl) was then injected into the well-stirred solution of nucleoside. After 15 minutes a well-vortexed mixture of a 0.5 M solution of bis (tri-n-butylammonium) pyrophosphate in anhydrous DMF (300 μl) and tri-n-butylamine (100 μl) was quickly injected and the reaction mixture was stirred for 10 minutes. A solution of 1% iodine in pyridine/water (98/2, V/V) (2 ml, 157 μmol) was then added. After 15 minutes excess iodine was destroyed by adding a few drops of a 5% aqueous solution of $NaHSO_3$ and the reaction solution was evaporated to dryness. The residue was dissolved in water and applied to a DEAE-cellulose column which was eluted with a linear gradient of 800 ml of each 0.05 M and 1 M TEAB. The fractions were characterized by NMR spectroscopy. The presence of the characteristic triphosphate group was confirmed by NMR as indicated in the figure below.

NMR SPECTRUM OF 3' URIDINE SPIROXIRANE TRIPHOSPHATE DERIVATIVE



ENZYME INHIBITION STUDIES WITH 3' URIDINE SPIROXIRANE TRIPHOSPHATE

The recombinant HIV-reverse transcriptase was expressed in the vaccinia virus construct VCF21 as described in previous progress reports. The enzyme was purified from culture fluids by column chromatography on DEAE cellulose and carboxy-methyl cellulose columns. The purified enzyme was used to synthesize DNA using a poly rAdT template and following the enzyme activity by measuring incorporation of ^{3}H labelled dTTP. The synthesized ^{3}H DNA was collected on acid washed filter, and counted in a scintillation counter. It was found that 3' uridine spiroxirane was an excellent inhibitor of the enzyme in this system. The inhibition was time and concentration dependent consistent with the irreversible inhibition associated with a suicide inhibitor. More detailed kinetic studies on reversibility however will be required to establish this and to distinguish the kinetics observed from those of a chain terminating inhibitor.

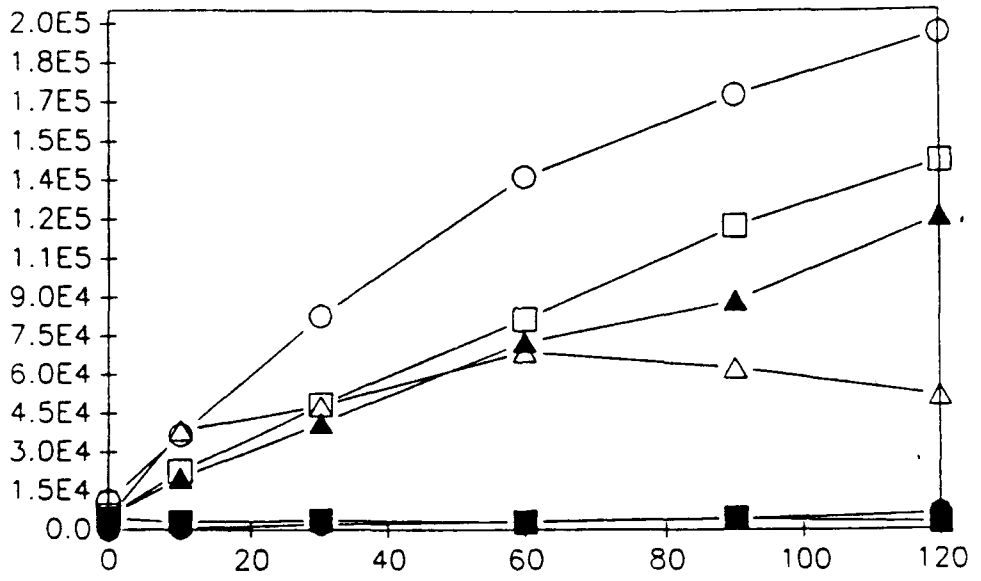


Figure: Activity of HIV-reverse transcriptase and inhibition by synthetic 3' uridine spiroxirane triphosphate

Key ○ control □ 0.05 μM △ .25 μM △ .25 μM ■ 2.5 μM ● Reagent blank

The triphosphate of 3' uridine spiroxirane was more potent as an inhibitor of the HIV reverse transcriptase than the triphosphate of AZT synthesized and tested in this system under the same conditions.

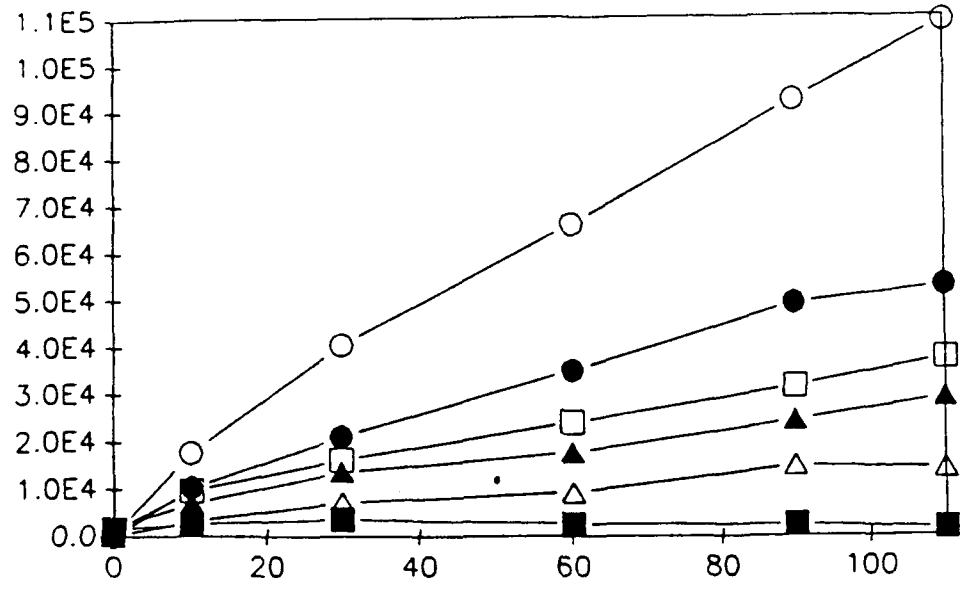

Figure: Inhibition of HIV-reverse transcriptase by synthetic AZT-triphosphate

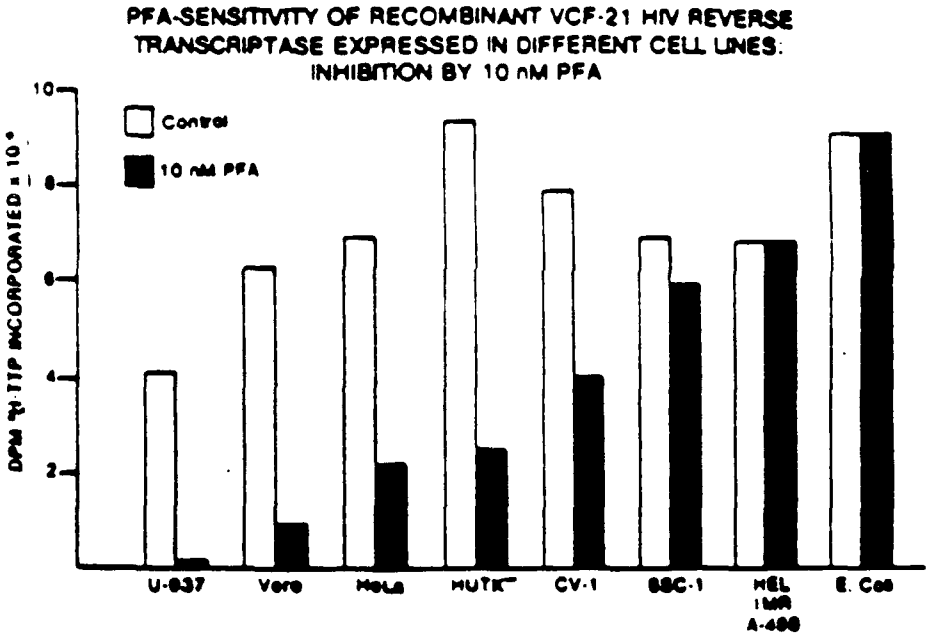
Key ○ control ● .05 μM □ .25 μM △ .25 μM ▲ 2.5 μM ■ Reagent blank

Preliminary experiments have been conducted to characterize further the nature of the inhibition by 3' uridine spiroxirane triphosphate. The inhibition is further confirmed as irreversible suicide type by the fact that addition of excess template does not reverse it, thus distinguishing it from that of a chain terminating inhibitor where new template would be expected to overcome the inhibition.

Expression of HIV-Reverse Transcriptase In Different Cell Lines.

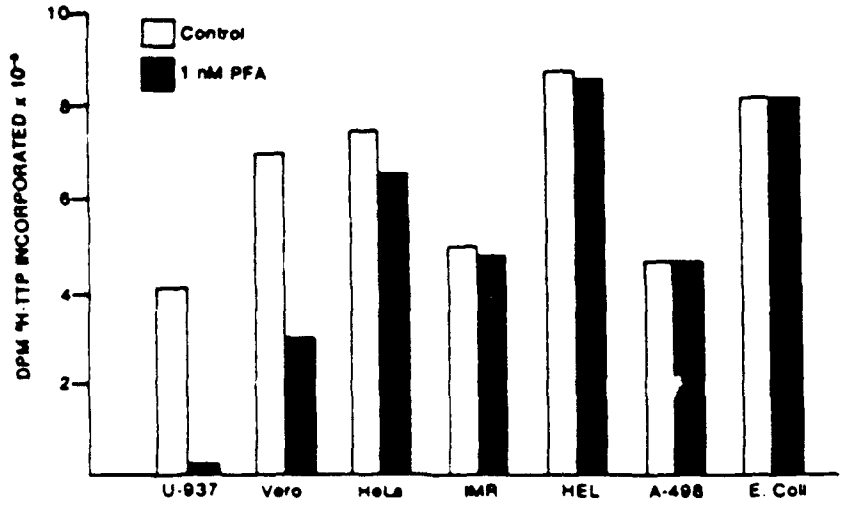
In order to determine if the recombinant HIV-reverse transcriptase was expressed in different forms depending upon the cell type, the vaccinia VCF-21 construct was grown in a number of different cell lines of both human, monkey and rodent origin. The expressed reverse transcriptase was tested for inhibition by Foscarnet at two different levels (1 and 10 nanomolar) and compared to the E. Coli recombinant HIV-RT (Kindly donated by Dr. Steven Hughes Fort Detrick M.D.) and the wild type HIV-RT. Both the wild type and E. Coli HIV-RT's were resistant to PFA showing essentially no inhibition at the 10nM level. Previous studies have shown that both enzymes have I_{50}'s for PFA in the 200-400 nM range. The recombinant HIV-RT expressed in eukaryotic cells however showed a range of phenotypes as indicated in figures 3 and 4 below. Both U-937 and Vero cells expressed enzyme sensitive to 1 nanomolar PFA, whereas human embryo lung and A-498 cells expressed RT-enzyme having wild-type sensitivity. Hela, HuTK- and CV-1 cells as observed previously expressed enzyme having intermediate PFA sensitivity



Sensitivity of Recombinant HIV-Reverse Transcriptases to 10 Nanomolar PFA.

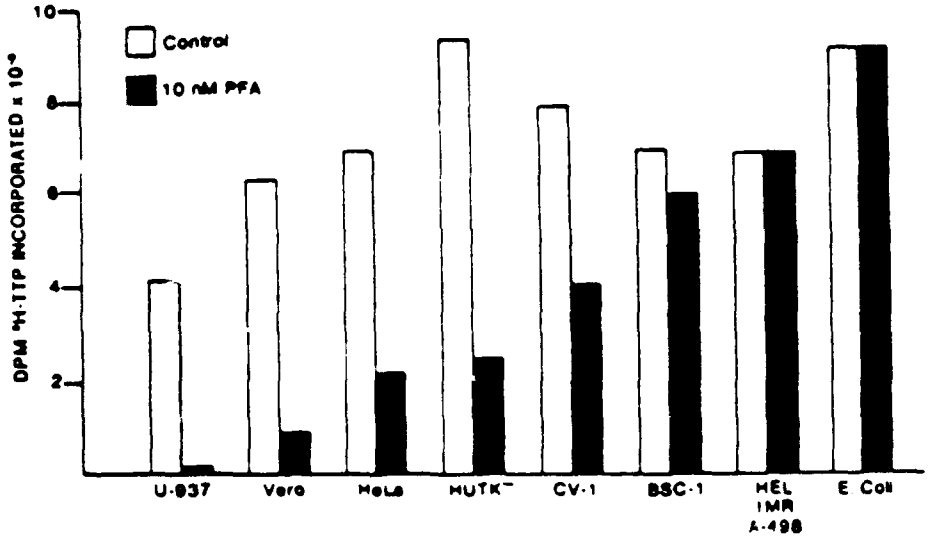
The VCF-21 vaccinia construct was grown in the indicated cell lines and the activity of the expressed reverse transcriptase was measured in the presence (dark blocks) or absence (open blocks) of 10 nanomolar PFA.

expressed RT-enzyme having wild-type sensitivity. Hela, HuTK- and CV-1 cells as observed previously expressed enzyme having intermediate PFA sensitivity



Sensitivity of Recombinant HIV-Reverse Transcriptases to 1 Nanomolar PFA.

The VCF-21 vaccina construct was grown in the indicated cell lines and the activity of the expressed reverse transcriptase was measured in the absence (open blocks) or presence of 1 nanomolar PFA. The height of the open blocks is a measure of the yield of recombinant enzyme activity in the different cell lines. Note the extreme sensitivity of the HIV-RT to PFA when expressed in the U-937 macrophage and vero monkey kidney cell lines.



Sensitivity of Recombinant HIV-Reverse Transcriptases to 10 Nanomolar PFA.

The VCF-21 vaccinia construct was grown in the indicated cell lines and the activity of the expressed reverse transcriptase was measured in the presence (dark blocks) or absence (open blocks) of 10 nanomolar PFA. Note that the enzyme produced in HEL IMR and A498 cultures resembles the E. Coli recombinant and wild type HIV-RT in being relatively resistant to PFA. The enzyme expressed in HeLa, HVTK and CV1 cells is of intermediate sensitivity and that expressed in U-937 and vero cells is maximally inhibited by PFA. Sensitivity of the vero enzyme remained following purification. Cross sensitizing experiments on mixtures of PFA sensitive and resistant preparations and measurements of RNAse H activity of all constructs are in progress

APPENDIX V

SUMMARY OF COMPOUNDS SHOWING SIGNIFICANT ANTIVIRAL ACTIVITY.

The table summarizes those compounds shown to have significant antiviral activity agaist one or more of the test viruses. The test data together with the I_{c50} are given in the sheets of Appendix 3.

AVS #S OF COMPOUNDS SHOWING SIGNIFICANT ANTI-VIRAL ACTIVITY

HIV	VACCINIA	PUNTA TORO	YELLOW FEVER

APPENDIX VI

SUMMARY OF SIGNIFICANT PROJECT ACCOMPLISHMENTS TO DATE AND RECOMMENDATIONS FOR FUTURE EXPLOITATION OF FINDINGS

PROJECT TITLE: SUICIDE INHIBITORS OF VIRAL POLYMERASES AS VIRAL PROPHYLACTICS AND BIOLOGICAL WARFARE ANTIDOTES.

a) Problems to be studied. This project will synthesize new types of antiviral drugs based upon suicide inhibitors of viral polymerases. These compounds will be screened in collaborative studies with the U.S. Army Antiviral Testing Facility for antiviral activity against a spectrum of 10 viruses of interest as military disease hazards and biological warfare agents.

b) Significance and Uniqueness. Suicide and affinity inhibitors of both DNA and RNA viral polymerases will be synthesized. This type of inhibitor contains a latent reactive moiety which selectively and irreversibly inactivates the viral enzyme. In preliminary studies, about 30 compounds with these potentialities have been synthesized and screened for antiviral activity in tissue culture. A number of active compounds including a new family - the nucleoside spiroxiranes - have been identified. Cytotoxicity assays in cultured T-lymphocytes also indicate favorable therapeutic indices for these types of drugs.

Two compounds, 2'3' sulfinyl cytidine hydrochloride and $2',0^2$ anhydrocytidine hydrochloride, which have proved to be highly effective against vaccinia virus in tissue culture, will be synthesized in larger quantities for further characterization and *in vivo* studies in the U.S. Army Antiviral Facility, Fort Detrick, MD. Congeners of compounds that have shown moderate activity against Punta Toro and yellow fever viruses will also be developed. Test data on selected compounds are given in the appendix.

Preliminary studies have begun on a series of nucleoside 5' oxaphosphorins and dioxaphospholes that are suicide analogs directed against enzymatic displacement reactions at the 5' α phosphate of the nucleotide substrate. The action mechanism and selectivity of the drugs will be characterized against viral and host nucleotide polymerases *in vitro*.

In the continuing studies, the range and selectivity of the nucleoside spiroxiranes will be extended by synthesizing additional members of the family. The suicide nature of their action and sensitivity will be determined in kinetic studies using viral and cellular DNA and RNA polymerases *in vitro*. Samples (75 mg) of each compound will be supplied to USAMRID for *in vitro* testing. Larger samples (2 g) of compounds showing activity *in vitro* will be supplied for further testing *in vivo*.

c) Relevance to USAMRDC mission studies. Suicide inhibitors represent a new class of antiviral drugs potentially capable of great selectivity. Orally administered antivirals could be militarily useful for temporary viral prophylaxis in emergency troop deployments to environments where advance vaccination is not possible, as antidotes following battlefield exposure to vaccinia-based or other biological warfare vectors, and in other unanticipated epidemic situations.

d) Estimated Project Duration and Personnel. Organic chemist (50% time), 1 or 2 graduate students. Duration 3 years.

e) Animal use. No animal or human use except USAMRDC in-house testing of antivirals supplied as requested.
