ABSTRACT

Unit costing is one of the important issues being faced by the Department of Defense (DoD). The ability to predict the cost required to generate a productive unit output is necessary because of current guidelines regarding the management of the limited resources available to the DoD. This thesis investigated the feasibility of developing such forecasts for the Naval Supply Systems Command (NAVSUP) using regression analysis. The analysis met with little success, most probably because the limited available data has only been recorded over the last 21 months due to the newness of the requirements of unit costing. The one positive result of the analysis was the discovery that some of the cost centers analyzed are affected by seasonality. In addition, the data for the last nine months appears to be better than the previous 12. This may be due to cost centers becoming accustomed to monitoring costs and outputs more precisely than has ever been done before.

I INTRODUCTION

A. Background

One of the results of the changing world environment during the late 1980's and the early 1990's is the so called "peace dividend." This "peace dividend" forces the Department of Defense to manage its limited monetary resources even more frugally than in the past. In an effort to manage the scarcity of the available money given to the Department of Defense (DoD) by Congress, DoD has issued some rather specific guidelines to the various military services. In fact, these guidelines are becoming ever more specific each year. The indications are that the guidelines will also be increasing in scope with each fiscal year. Gone are the days when each Service was able to use a unique system. Consolidation and sameness are the new philosophies of the Department.

The current guidelines require the use of unit costing. The current Comptroller of the Department of Defense guideline's state:

Every manager and employee is encouraged to seek ways to become more efficient and effective. . . .a DoD-wide cost per output, or unit cost, resourcing system will be developed for a number of major functional, or business, areas to enhance visibility of costs and contribute to better management of resources. . . .All base operations costs will be considered part of doing business and will be treated as an overhead function or General and Administrative (G&A) expense recorded in the appropriate business area accounts. . . .The unit cost concept is that

all of the costs incurred at an activity, or within a function, should be related to an output of the activity. . . .The goal is to have each product or output bear as accurate a cost as possible. . . .In addition to providing a means to consider costs as part of day-to-day decision making, unit cost provides visibility of cost drivers. Cost drivers can be those actions taken that contribute to the accomplishment of an output or a product at a significant cost and should be evaluated for value added. [Ref 1: pp. 1-2]

The Naval Supply Systems Command (NAVSUP) is one such command that must follow this philosophy. Within NAVSUP the above mentioned unit cost approach is called the productive unit resourcing system (PURS). NAVSUPINST 7000.21A describes the responsibilities of NAVSUP controlled personnel in the management of the Operation and Maintenance, Navy (O&M,N) budget execution process under the productive unit resourcing (PUR) system [Ref 2: p. 1]. The concept expressed by the NAVSUP Instruction is that:

Under the productive unit resourcing system, NAVSUP commits to fund workload at the required level of performance; i.e., field activities will be funded on the basis of actual work performed vice the fixed workyear/cost funding methodology used previously. [Ref 2: p. 1]

Although NAVSUP's concept was developed before the Department of Defense guidance, it reflects basically the same philosophy.

As a consequence of the above directives, it is becoming more important each year to be able to predict just how much funding will be required at each activity, given their anticipated level of production output. In particular, NAVSUP wants the ability to predict dollar amounts each cost center

will spend per productive unit of output. The NAVSUP concept emphasizes that work units are dependent upon many various externalities. One such an example is Desert Storm, as it obviously caused many cost centers to generate many more productive units than anticipated when making the initial fiscal year projections.

B. Thesis Objective

At NAVSUP's request, an investigation was conducted of the feasibility of using linear regression analysis for forecasting the costs associated with a unit of basic output for a wide variety of NAVSUP cost centers.

The first step of the analysis was an examination of the data in Appendix A. The results were that of the 156 cost centers 53 had no Units data available and therefore could not be analyzed. The definitions of the cost centers and a short description of what encompasses each cost center's productive units as described by NAVSUPINST 7000.21A are listed in Appendix B.

The second step was to subject the data of those cost centers for which sufficient data existed to analysis by basic statistical forecasting methods, including regression and seasonality effects, in an attempt to develop a predictive model for each of these cost centers.

C. Scope, Limitations, and Assumptions

The data furnished by NAVSUP for each of the 103 cost centers analyzed covered the time interval between October 1989 and June 1991 (21 months). The data was provided in a *Lotus 123* format. Only this data was analyzed.

With the exception of the data entries identified by a negative value, all data furnished was assumed to be correct. The negative numbers observed in both the Units and Dollars fields were assumed to be errors and were not used in the analyses.

D. Preview

Chapter II begins with a description of the preliminary data analysis. It discusses how the furnished data was reorganized and the initial problems found with the data. The chapter also explains the regression model and its associated assumptions.

Chapter III presents the analyses of the data, describing how the regression functions were derived and presenting the results of statistical tests.

Chapter IV contains the analyses of the data using seasonality indices computed from that data. This chapter includes regression analyses of the deseasonalized data. The chapter also addresses potential problems with using the resulting regression functions.

Chapter V presents a summary of the thesis, conclusions drawn from the analyses, and recommendations for what to do next.

II ANALYSIS OF THE PROBLEM

This chapter deals with the preliminary data analysis. It discusses how the furnished data was reorganized into a more useable form and the initial problems found with the data. The chapter also explains the regression model and its associated assumptions.

A. Activities and Cost Centers

The data files were formatted into activities and cost centers. A cost center is a part of the activity that has a specific productive unit function associated with it. For example, DB is a disbursing cost center whose productive unit is primarily the number of checks issued. An activity can contain several different cost centers, and most cost centers are located in more than one activity. The data furnished consisted of 18 activities and 156 cost centers. Appendix A contains a glossary of acronyms and the listing of activities and cost centers.

The analysis was done strictly on the data. No attempt was made to determine the basis for what consists of a work unit or its output for any of the cost centers. The differences in missions of the various activities also was not considered in the analysis.

B. Data

All data analyzed was furnished by NAVSUP. The data was contained on a floppy disk in *Lotus 123* format and was divided into two files. One file contained Fiscal Year 90 data and the other contained Fiscal Year 91 data. Each row of data consisted of one cost center with the number of units of production listed in monthly order, followed by a listing of the monthly dollar amounts.

The first step of the analysis was to convert the files into a useable format which would facilitate statistical analysis. The two files were first converted into one large file. Then the file was separated into individual files, one for each activity. An activity is the physical command, for example ASO is an activity.

Each activity's file was subdivided further into its separate cost centers.

Finally, the data for each cost center was converted from one long row into three columns consisting of month and year, units of output, and dollars expended. The NAVSUP data in this final format is as shown in Appendix B.

C. Presumed Accuracy

The data furnished and as evaluated in its final form was assumed, with the exceptions listed below, to be a complete and accurate representation of the true circumstances.

1. Missing Values

The data for 84 of the 156 cost centers showed zero-filled or blank costs and/or units for at least one of the months. Those observations with blank or zero data were not used in the analysis. Fifty-three cost centers had completely blank or zero units of output.

2. Negative Values

There are also several instances of data containing negative units or dollars. When queried about the negative values, NAVSUP personnel indicated that such occurrences are impossible and most likely were simple errors. It was agreed upon with NAVSUP that the best and most consistent way to handle the negative data was either to ignore the data or simply disregard the negative sign. The first option was chosen because the concern that disregarding the negative sign would result in badly distorted observations. Appendix A lists the data with the negative values included.

D. Time Lag

One of the early concerns about the furnished data was whether it contained any lag time between reporting the units and when the obligation of dollars occurred. Telephone conversations with NAVSUP personnel revealed that the data furnished had already been corrected for any possible lag times. This was accomplished by the reporting method. Although the reported work units may have occurred at some

previous time in relation to the period reported, the obligations of dollars were recorded during the corresponding month in which the units were finally identified and shown as completed.

E. The Regression Model

Since the desire of NAVSUP was to predict the amount of dollars spent to generate a certain number of productive units, the number of productive units was assumed to be the independent variable and the costs (dollars spent) to be the dependent variable. The regression model used assumed a simple linear relationship between the two variables over their ranges of possible values.

The basic goal of linear regression analysis is the derivation of a formula for a straight line that best represents the actual relationship between the dependent and independent variables, dollars and units. The least squares approach is the usual way to accomplish this. The basic principle is that there exists an infinite number of lines that can be drawn on a plot representing the data, but there is only one that best fits the data in the sense of least squares. With this line the sum of squared prediction errors are the smallest in relation to the actual observations. The procedure is common and complete details on the process can be found in most statistical textbooks (see, for example, Reference 5).

1. The Regression Model

The regression model is: $Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$, where

- X_i is the independent variable, units for this analysis;
- Y_i is the dependent variable, dollars for this analysis;
- β_0 is the Y intercept of the regression line. It indicates the point where the regression line actually intercepts the Y axis. It estimates the average value of Y when X equals zero. [Ref 3: p. 18]
- β_1 is the slope of the regression line, and;
- ϵ_i is the residual error associated with the ith observation. This term represents the difference between the model's result and the actual observed value Y_i for a particular X_i . This term does not appear in the fitted lines.

The least squares formulas for β_0 and β_1 and other important formulas of use in regression analysis are:

$$\beta_1 = \frac{\sum (X_i - \bar{X})(Y_i - \bar{Y})}{\sum (X_i - \bar{X})^2};$$

$$\beta_0 = \bar{Y} - \beta_1 \bar{X};$$

$$\text{TSS} = \sum (Y_i - \bar{Y})^2;$$

$$\text{ESS} = \sum (Y_i - \hat{Y}_i)^2;$$

$$\text{RSS} = \sum (\hat{Y}_i - \bar{Y})^2;$$

$$\hat{Y}_i = \beta_0 + \beta_1 X_i;$$

$$R^2 = \text{RSS}/\text{TSS}.$$

In these expressions,

- X_i = an observed value of the independent variable;
- $\bar{X}$ = average of all observed values of the independent

variable;

- Y_i = an observed of the dependent variable which is associated with the observed value, X_i , of the independent variable;
- $\bar{Y}$ = average of all observed values of the dependent variable;
- $\hat{Y}_i$ = predicted value of the dependent variable associated with the observed value, X_i ;
- TSS = total sum of squared deviations of the dependent variable from its mean value;
- ESS = error sum of squares, or unexplained sum of squared deviations of the observed values of the dependent variable from the corresponding regression estimates;
- RSS = regression sum of squares, or sum of squared deviations of the regression estimates from the mean of the observed values of the dependent variable;
- R^2 = coefficient of determination. R^2 indicates the explanatory power of the regression model.

2. Range of Accuracy Given by a Regression Formula

A common error that sometimes is made when using a regression formula is assuming that the model is accurate outside the range of the independent variable used for the model creation. An example of this is the value given by β_0 . The fact that β_0 does not go through the origin does not mean that the model is necessarily incorrect. This value is simply a place marker indicating a starting point for the regression line. Unless the independent variable had an observed value of zero, one should not generalize beyond the range of the data by claiming that the Y intercept is an expected value of the dependent variable when the independent

be a fixed or start-up cost causing the value going from zero to a very large value for the first unit of output.

Similar problems may arise if an attempt is made to use a model to estimate the value of the dependent variable for values of the independent variable greater than those used to derive the regression formula.

3. Specific Assumptions

The specific regression assumptions made for the analyses in Chapter III include:

1. No specification error.
 - a. The relationship between units and dollars is linear within each cost center.
 - b. No relevant independent variables have been excluded.
2. Assume the measurement error has a mean of zero.
 - a. The independent variable is measured without error.
 - b. The dependent variable is assumed to have error (some of which may be measurement error) associated with ESS.
3. The following assumptions concern the error term, ϵ_i :
 - a. for each observation, the expected value of the error term is zero ($E(\epsilon_i) = 0$);
 - b. the variance of the error term is the same for all observations;
 - c. the error terms are not correlated;
 - d. the error terms, ϵ_i , are normally distributed. [Ref 3: p. 26]

III ANALYSIS OF DATA

The least squares method was used to develop the coefficients in the regression equation for each cost center having sufficient data to analyze. Each resulting regression function and corresponding set of residuals were examined to determine how successfully the least squares line fit the data.

A. Coefficient of Determination

The first evaluation was done to see how well the regression function accounts for variations in the dependent variable. This was accomplished by examining the values of the coefficient of determination, R^2 . Its value represents the proportion of variation in the dependent variable explained by the regression function. The possible values of the measure range from 0 to 1. At the one extreme, when $R^2 = 1$, the regression function completely accounts for the dependent variable's variation. This implies that all observation pairs (X_i, Y_i) fall on the regression line. An extremely low R^2 , one near 0, indicates that the dependent variable has virtually no linear dependency on the independent variable [Ref 3: pp. 21-24].

Simple interpretations of R^2 make the coefficient of determination one of the most important measures of the adequacy of prediction equations....A large value of R^2 does not necessarily guarantee accurate prediction, but it

should be required before undue claims are made about the fitted model. [Ref 4: p. 83]

B. Hypothesis Testing

After examining the R^2 for each equation the next evaluation was to test whether the regression line actually has a slope other than zero (as represented by β_1). This is best accomplished through a procedure called hypothesis testing.

Hypothesis testing involves setting up a hypothesis that allows for making a decision from two possible outcomes. The desired hypothesis, by custom, is usually called the null hypothesis, and is denoted by H_0 . Typically, it states that a certain parameter of a probability distribution has a specified value. The alternative hypothesis, denoted as H_a , usually states that the parameter does not have that value; and may specify what its alternative value is. The objective of hypothesis testing is to either reject the claim of the null hypothesis and therefore accept the alternative hypothesis; or not to reject the claim of the null hypothesis. The null hypothesis will not be rejected in favor of the alternative claim unless sample evidence contradicts it and provides strong support for the alternative assertion.

The testing of hypotheses is accomplished through a test procedure. This procedure is a rule, based on sample data, for deciding whether or not to reject the null hypothesis.

A test procedure is specified by:

- a test statistic, which is a function of the sample data on which the decision to reject H_0 or not reject H_0 is to be based; and
- a rejection region, which is the set of all test statistic values for which H_0 will be rejected. [Ref 5: p. 279]

The null hypothesis will then be rejected if and only if the observed or computed test statistic value falls in the rejection region.

The hypotheses of concern for the regression models are stated as:

- $H_0: \beta_1 = 0$ (the slope of the regression equation is zero); and
- $H_a: \beta_1 \neq 0$ (the slope of the regression equation is something other than zero).

If H_0 is true, it implies that the independent variable has no influence on the dependent variable (at least not through a linear relationship). Rejection of H_0 in favor of H_a leads to the conclusion that the independent variable significantly influences the dependent variable in a linear fashion. The rejection of H_0 means that a trend has been detected. However, nothing is implied concerning the quality of fit of the regression line. That is what R^2 is used for.

The test statistic that is used for testing whether $\beta_1 = 0$ is the t value. The t value is computed by dividing the estimated β_1 by the standard error of the estimate of the coefficient. This standard error is an estimate of the standard deviation of the slope estimate (β_1).

The rejection region for this test comes from the t distribution table. To test $H_0: \beta_1 = 0$ against $H_a: \beta_1 \neq 0$ a two-tailed test is used. This test involves a rejection region on both the left and right ends (tails) of the distribution. A rejection region containing 5 percent of the total probability distribution is typically used. With the two-tailed test this means that 50 percent of the rejection region lies in either tail of the distribution. Appendix C is an abridged t table, covering only the rejection region for a 5% significance level and for the degrees of freedom for the data analyzed. Degrees of freedom is defined as the number of observations minus the number of estimated parameters (in this case β_1), minus one. Thus, for the regression functions analyzed in this thesis the degrees of freedom is the number of observations minus two.

For this test, the null hypothesis can only be rejected if and only if the computed test statistic value falls in the rejection region. Therefore, if the absolute value of the test statistic is greater than the value from the t table the decision is to reject $H_0: \beta_1 = 0$, and accept the $H_a: \beta_1 \neq 0$ at the five percent significance level. The analysis as done was only concerned with a significance level of five percent. The t value can be converted into its specific significance level with the use of formulas, tables or computer software programs. By doing this the specific significance level provided by the regression model results can be derived.

C. Results of Analysis

Table 1 presents a compilation of the results of the regression analyses of the data from Appendix B, listed in descending order of R^2 values. The first two columns specify the cost center and the activity to which that particular cost center belongs. The regression function shows the coefficients determined by the least squares method. The column titled d.f. indicates the degrees of freedom for the particular regression function. The t value column is the calculated test statistic to be used for testing the null hypothesis of $\beta_1 = 0$.

As Table 1 shows, only eight of the 103 cost centers have a R² that is greater than 0.5. The lack of a good fit for most of the remaining 95 cost centers is reinforced through the analysis of the slope using the hypothesis test described above. That test indicates that only 29 cost centers in Table 1 have a slope not zero at 5 percent significance. Table 2 lists these 29 cost centers by activity.

The activity labeled NPFC (Naval Publications and Forms Center) has six cost centers, all of which have significant regression results. This is quite an accomplishment considering that the six cost centers represent the entire set of its cost centers. All cost centers of the activity labeled WASH (Naval Regional Finance Center Washington D.C) also have significant regressors.

IV ADDITIONAL ANALYSIS

Since the regression formulas in Table 1 appear to be of very little help to NAVSUP in connecting budgets and outputs it was decided to look at the possibility of seasonal variations.

A. Seasonal Correction

When using data that is reported in a sequential time pattern, a seasonal variation in demand or usage is not uncommon. These seasonal usage patterns are usually identified through a typical recurring period of high and low usage. Since the data supplied meets the requirements to be a time series it was decided to attempt the regression analysis with deseasonalized data.

The deseasonalization of the data was accomplished by using the fiscal year 90 data for determining the seasonal indexes, then running the regression analysis on the deseasonalized fiscal year 91 data. The computations of the seasonal indexes were accomplished using the following procedure: for each cost center the work units from the months of October 1989 through September 1990 were averaged. Each monthly work unit was then divided by this average value. The result of this division is the monthly seasonal index. Each month's units and dollars for fiscal year 91 were then divided

by the corresponding monthly index figure. The results are deseasonalized values of units and dollars [Ref 6: pp. 60-62] Table 3 illustrates the steps of the process for Naval Supply Center Charleston's CP cost center.

B. Analysis of Seasonal Data

The fiscal year 91 deseasonalized data was then used for a regression analysis which is summarized below in Table 4. The table is arranged identically to that of Table 1.

Appendix D contains the seasonality indices and regression analyses for the first 50 cost centers listed in Table 4. The other cost centers showed virtually no seasonality effect, as their indices for all months were very close to 1.0 and therefore have very little affect on the data.

As Table 4 shows, the number of cost centers with a R² greater than 0.5 has increased from the eight in Table 1 to 26 in Table 4. This appears to be good news. There is further good news. With only a partial year of data available to compute the regression function and the degrees of freedom for the hypothesis test for the slope being reduced as a consequence, 29 cost centers can still reject the hypothesis that the slope is zero. These 29 cost centers are listed in Table 5 by activity.

TABLE 5. COST CENTERS FROM TABLE 4 HAVING $B_1 \neq 0$

<u>Activity</u>	<u>Cost center</u>

Table 5, like that of Table 2, shows that the activity labeled NPFC is still the most "efficient" with regards to regression functions.

C. Regression analyses on the last nine months of data ignoring seasonality

Since the regression analyses in the preceding section used only the fiscal year 91 data, there was the possibility that the raw unseasonalized data from fiscal year 91 would also result in a significant improvement from the analysis of the entire 21 months. It could have been possible that the cost centers could, after one year of reporting the required information, have improved their tracking of outputs and the costs required to create them. The regression analyses of 50 of the cost centers are presented in Appendix D along with the

associated seasonalized analyses. Just using the fiscal year 91 data did increase the number of R^2 values greater than 0.5 from eight in Table 1 to twelve, but only ten of these cost centers were able to reject the null hypothesis that the slope coefficient β_1 is zero.

D. Implications of Deseasonalization of Data

Comparing Tables 1 and 5 suggests that some of the cost centers benefit more from the deseasonalization than others. For example, the SP, LP, and FR cost centers appear to benefit from considering seasonality effects. Cost center DB is better without the deseasonalization. Those cost centers whose seasonality indices all hover close to 1.0 will, of course, show little benefits from considering seasonality as it was computed in this thesis.

E. Reseasonalization of Data

To make correct use of the regression functions for deseasonalized data the following procedures must be followed.

1. The projected work units must be divided by the appropriate monthly seasonal index.
2. The forecasted deseasonalized costs associated with these work units are obtained from the appropriate cost center regression function.
3. The resulting costs from step 2 must then be multiplied by the monthly seasonal index to obtain the estimated costs of producing the projected units used in step 1.

The seasonality indices should also be updated after each subsequent year's historical data has been added to the data

base. The update is accomplished by the adding each month's output value to the previous year's values to get monthly averages and an annual average of the number of complete past years.

There are several ways to compute seasonal indexes with more than two years of data. The type chosen should be one that the user is comfortable with. Most management science text books include at least one method of computing seasonal indices. (See, for example, Reference 6.)

F. Potential Problems

Potential serious problems from using the results of these analyses are possible. The sample size is rather small for gaining much benefits from regression analysis. In addition, seasonality indices generated with only one year's worth of data are suspect. More months worth of data are necessary to feel confident about regression analysis results. How much data is necessary depends, of course, on several things. One is the urgency to get some sort of forecast for the dollars needed. Another is the sense of importance that the cost center attaches to keeping accurate records of outputs and expenditures associated with them. Both should be motivated by shrinking of future budgets. Finally, the model used in the analyses above was a simple linear relationship between outputs and dollars. That may, in fact, be an incorrect assumption. Higher order models may be much more appropriate.

These other models since they are not linear were not investigated or considered. An understanding of what each cost center does, and how the work units and outputs are computed will also be necessary to refine the model.

V SUMMARY, CONCLUSIONS, AND RECOMMENDATIONS

A. Summary

This thesis concerned itself with regression analysis of data furnished by NAVSUP. The analyses of the data resulted in very limited success. Without any manipulation of the data, only eight of the 103 cost centers having sufficient data to be analyzed exhibited results that, at the 5 percent significance level, showed the dollars expended to be linearly related to the work units produced.

Applying seasonal indices, while producing improved results in the sense of R^2 , still failed to produce any larger number of cost centers able to reject the hypothesis that the slope is zero. These larger R^2 values do suggest that consideration of seasonality effects has merits. When a larger number of months are available one may be able to determine which cost centers are in fact really subject to the effects of seasonalized demands for their outputs.

There was one activity (Naval Publications and Forms Center) whose data consistently met the requirements set up in this thesis for significant analysis. This activity's reporting methods and quality control of the reporting methods appear to be better than the other activities. Of course their requirements may also be less demanding to fulfill than

the other activities. An examination of each cost centers' unit output is necessary to make a better judgement on this matter.

B. Conclusions

It is apparent from the analyses that a simple linear regression model does not predict with much confidence the amount of money it will cost to produce a certain number of units of output. As Tables 1 and 4 show, the R^2 values are less than 0.5 for almost 75 percent of the cost centers. Those cost centers with an R^2 of less than 0.5 have less than 50 percent of the dollars spent explained by the units of output with respect to the least squares model.

The application of seasonality indices to the cost center data does appear to contribute significantly to an increase in the number of cost centers having a higher R^2 . However, only the last nine months of data can then be used.

C. Recommendations

1. It is recommended that data continue to be collected and regression analyses applied. Hopefully, as the amount of data grows, a linear or nonlinear function should start to become evident for forecasting the dollars needed to create the demanded outputs.

2. It should come as no surprise that some of the cost centers considered are affected by the influence of seasonal

changes in their demand pattern. These cost centers should be further evaluated to determine the extent of this influence.

3. It is recommended that the cost centers pay closer attention to record keeping, both of outputs and the expenditures that create them.

4. Since there is yet no good simple linear fit for many of the cost centers, a search should be conducted for the possibility of either a hidden regressor that is keeping the units from accurately predicting dollars spent or a function that better represents the relationship between output and input.

5. The one activity for which the linear regression seems to give good results from both the unseasonalized and the seasonalized analyses is Naval Publications and Forms Center. All of its cost centers appear to have sufficient data available to provide a reasonably accurate linear regression forecasting function. This suggests that the activity has developed the necessary skills to report accurately its units and costs. This possibility should be investigated and, if found to be true, the activity should be contacted and asked to share their skills with the other activities in NAVSUP.

6. A final thought concerns the Department of Defense guidance. This guidance is quickly changing and becoming more demanding regarding the use of resourced units. This new emphasis will continue to create considerable turbulence throughout the Department of Defense. NAVSUP should review

their PURS system to determine if the output units and costs calculations currently being used are really valid.

APPENDIX A

This appendix is a glossary for acronyms used in the body. It also lists the activities full names, and the cost centers with a short definition of the measurement of work that constitutes the Units for each cost center as defined by NAVSUPINST 7000.21A.

A. Glossary

Activity: A physical command, that has several cost centers.

ATAC: Advanced Traceability and Control

β_0 : Y axis intercept of the regression function.

β_1 : Slope of the regression function.

COSAL: Coordinated Shipboard Allowance List.

Cost Center: A part of the activity that has a specific productive unit function associated with it.

DoD: Department of Defense.

ESS: Error sum of squared deviations.

FMSO: Fleet Material Support Office

ICP: Inventory Control Point

M-BARRELS: 42,000 gallons.

NAVSUP: Naval Supply Systems command.

NMTO: Naval Material Transportation Office

NRCC: Naval Regional Contracting Center.

NRFC: Naval Regional Fiance Center.

NSC: Naval Supply Center.

PPR: Planned Program Requirements.
PUR: Productive unit resourcing.
PURS: Productive unit resourcing system.
RSS: Regression sum of squared deviations.
 R^2 : Coefficient of determination, an indication of the explanatory power of the regression model.
TSS: Total sum of squared deviations.
X: Independent variable in regression formula.
Y: Dependent variable in regression formula.

B. Activities

ASO: Aviation Supply Office
CHASN: NSC Charleston
GLAKE: NREC Great Lakes
JAX: NSC Jacksonville
NAP: NRCC Naples
NMTO: Navy Material and Transportation Office
NORVA: NSC Norfolk
NPFC: Naval Publications and Forms Center
NRCC: Naval Regional Finance Center
OAK: NSC Oakland
PEARL: NSC Pearl Harbor
PEN: NSC Pensacola
PHIL: NRCC Philadelphia
PUGET: NSC Puget Sound
SAN: NSC San Diego

SDCC: NRCC San Diego

SPCC: Ships Parts and Control Center

WASH: NREC Washington D. C.

C. Cost Center Codes

<u>Code</u>	<u>Name & definition of Units</u>
AH	ATAC Hub; used by NSC Norfolk and San Diego Productive Unit: Line item receipts.
AP	Allowance Products; used by ICP Productive Unit: Allowance documents prepared.
AT	Air Terminal; used by NMTO Productive Unit: Undefined by NAVSUPINST 7000.21A.
CD	Cross Disbursing; used by NREC Glakes Productive Unit: Undefined by NAVSUPINST 7000.21A.
CO	COSAL Outfitting; used by NSCs Productive Unit: Undefined by NAVSUPINST 7000.21A, unused in analyses due to insufficient data for any cost center.
CP	Civilian Payroll; used by NSC, ICP, NREC Productive Unit: Graded/ungraded pay accounts.
DB	Disbursing; used by NSC, NREC Productive Unit: Checks issued, invoices processed.
DP	Data Processing; used by ALL Productive Unit: Review of cost, unused in analyses due to insufficient data for any cost center.
FO	Fuel Ops; used by NSC Productive Unit: M-Barrels pumped/operations.
FR	Fund Resource Accounting; used by NSC, ICP, NREC Productive Unit: Transactions posted.
FS	Fleet Support; used by FMSO Productive Unit: Undefined by NAVSUPINST 7000.21A, unused in analyses due to insufficient data for any cost center.

<u>Code</u>	<u>Name & definition of Units</u>
GA	General & Administrative; used by ALL Productive Unit: Percent of productive resources, unused in analyses due to insufficient data for any cost center.
IC	Inventory Control; used by ICP Productive Unit: Line items managed.
IF	Provisioning; used by ICP Productive Unit: Line items reviewed.
LP	Large Purchase; used by NSC, ICP, NRCC Productive Unit: Contract action, (weighted) purchase action.
MA	Material Accounting; used by NSC, ICP Productive Unit: Transactions posted.
OF	Outfitting Support; used by NSC Productive Unit: Undefined by NAVSUPINST 7000.21A, unused in analyses due to insufficient data for any cost center.
PD	Physical Distribution; used by NSC Productive Unit: Movement units.
PP	Personal Property; used by NSC Productive Unit: Transactions (weighted).
PR	Program Requirement; used by ICP Productive Unit: PPRs generated.
QT	QEALT; used by ICP Productive Unit: Undefined by NAVSUPINST 7000.21A, unused in analyses due to insufficient data for any cost center.
RP	Maint Real Prop; used by ALL Productive Unit: Undefined by NAVSUPINST 7000.21A, unused in analyses due to insufficient data for any cost center.
SM	SERVMART; used by NSC Productive Unit: Undefined by NAVSUPINST 7000.21A.
SP	Small Purchase; used by NSC, ICP, NRCC Productive Unit: Contract action, (weighted) purchase action.

APPENDIX B

The following is a listing of all the data furnished by NAVSUP. The data is shown in the final format after its conversion for analysis. It is arranged in alphabetical order by activity and cost center. The cost centers that have mostly zeros or -- (representing a blank) for entries were not considered for analysis.

APPENDIX D

Each page in this appendix consists of a unique cost center with its associated Units and Dollars columns from Appendix A. The two columns to the right of Units and Dollars and beginning with the OCT90 row represent the deseasonalized Units and Dollars columns, respectively. The figure just under "AVG" is the average monthly productive units of fiscal year 1990. The column labeled INDEX depicts the monthly seasonal index for that particular cost center. The two tables contained in the middle of the page contain the regression output for fiscal year 1991 data only. Although zeros and negative values may be shown in the data they were ignored in the analyses.
