FOREWORD

This technical report covers work performed under Air Force Contract F33600-87-C-0464, DAPro Project. This contract is sponsored by the Manufacturing Technology Directorate, Air Force Systems Command, Wright-Patterson Air Force Base, Ohio. It was administered under the technical direction of Mr. Bruce A. Rasmussen, Branch Chief, Integration Technology Division, Manufacturing Technology Directorate, through Mr. David L. Judson, Project Manager. The Prime Contractor was Integration Technology Services, Software Programs Division, of the Control Data Corporation, Dayton, Ohio, under the direction of Mr. W. A. Osborne. The DAPro Project Manager for Control Data Corporation was Mr. Jimmy P. Maxwell.

The DAPro project was created to continue the development, test, and demonstration of the Integrated Information Support System (IISS). The IISS technology work comprises enhancements to IISS software and the establishment and operation of IISS test bed hardware and communications for developers and users.

The following list names the Control Data Corporation subcontractors and their contributing activities:

SUBCONTRACTOR

ROLE

Control Data Corporation	Responsible for the overall Common Data Model design development and implementation, IISS integration and test, and technology transfer of IISS.
D. Appleton Company	Responsible for providing software information services for the Common Data Model and IDEF1X integration methodology.
ONTEK	Responsible for defining and testing a representative integrated system base in Artificial Intelligence techniques to establish fitness for use.
Simpact Corporation	Responsible for Communication development.

SECTION 1

SCOPE

1.1 Identification

→ This specification establishes the 'as built' design of the Message Processing Unit component of the Network Transaction Manager Subsystem.

1.2 Functional Summary

The Network Transaction Manager (NTM) Subsystem provides the control and support services to application processes that are grouped together logically in clusters called Application Process Cluster (APCs). These application processes communicate with one another by sending messages via the NTM. The NTM delivers these messages to the destination application processes while also providing other services for the APs such as message pairing, AP initiation, and message queuing.

2.2 Terms And Abbreviations

- 1. Interhost Communication Primitives (IHC's) - A set of routines used by the NTM to interface to the operating system or to other operating systems which have an NTM running. They are always system dependent.
- 2. Interprocess Communication Primitives (IPC's) - A set of routines used to communicate between two processes on the same computer. They are always system dependent.

SECTION 3

REQUIREMENTS

3.1 Structural Descriptions

The Message Processing Unit has three stages of operation: Start-up, Input Processing, and Shutdown. The Monitor Application Process (Monitor AP) initiates the first instance of and MPU, the Monitor MPU. All other MPUs are then initiated by the Monitor MPU.

3.2 Functional Flow Description

The Start-up stage of an MPU begins with getting the MPU's process name from the operating system and creating both high- and low-priority mailboxes. The MPU then sends a message to the Monitor AP requesting the status of the tables on the cluster and waits for a response from the Monitor AP. If the response does not arrive within a given amount of time, the MPU will send an "AP CLUSTER TERMINATING" message to the Monitor AP and will then proceed to terminate. If the message does arrive saying that the tables are correct, then the MPU will populate its tables with the information saved in local files via table initialization procedures. The MPU then sends an "AP CLUSTER ALIVE" message to the Monitor AP and waits for final start up instructions.

As a final instruction, if an error occurs during the IISS start-up, the Monitor AP will instruct each Message Processing Unit to terminate. Also, if the final instruction message does not arrive within a certain period of time, the MPU will begin the AP Cluster termination process on its own. However, if the IISS start-up is successful, then the Monitor AP will send a "HOST ACTIVE" message to signal the MPU that Start-Up is complete. The MPU is now ready for its second phase of operation: Input Processing.

During the Input Processing stage, the MPU remains available to the users who are logged onto the IISS and to other application processes. User application processes can communicate with one another and initiate other application processes by sending messages through the MPU. The MPU processes these messages in two phases: Manage Message, and Process Message.

The Manage Message Phases authorizes the message, verifies the message category, assigns a serial number, and completes the header of messages from on the cluster. If the message is from another cluster, Manage Message verifies that the message arrives at the correct destination. If a message error occurs, the MPU will send an error message to the source AP. If a system error occurs, the MPU will send an error message to the Monitor AP. All messages are logged in Manage Message. This is also where the type of processing to be done on the message is determined. Messages destined to go off-host are sent to the Communication cluster's MPU; messages destined to stay on-host

but off-cluster are delivered to the off-cluster MPU; and messages destined for on-cluster are processed by phase two of Input Processing: Manage Process.

Manage Process handles each message destined for the AP Cluster according to its message category and type. Some messages cause the initiation of other application processes in the IISS; others are simply delivered to the destination AP. All message processing done by the MPU requires table access. Information about individual AP instances and types of APs are kept in several tables.

For example, every time an initiation message arrives at the Manage Process phase, the MPU must check the AP Characteristics Table to be sure that the AP can be started by that type of initiation message. If the AP can be initiated by that type of message, the MPU must then check the AP Information Table to be sure that the maximum number of instances allowed has not yet been reached. Finally, if the AP is initiated successfully, an AP Status Table entry is created for that AP. The AP Status Table has an entry for every instance of an application process that is communicating via the IISS. There are many different types of application processes running under the IISS and all are at different stages of processing at any given moment. All of this information is stored in tables for the MPU's use in order that all kinds of messages may be processed.

Also during the Input Processing phase of the MPU, a timer is set to a fixed length of time. When the timer goes off, a checking routine is invoked. The checking routine looks at certain tables and processes each entry in the table according to its status. For example, the Message Pair table has an entry for each message that requires a response. If the time-out time on the entry has passed (compared to the system's time) then the MPU deletes the entry and send a "TIME-OUT ERROR" message to the Monitor AP. The checking routine also processes messages that have been stored up in queues. For example, if the MPU tries to deliver a message to an AP whose mailbox is full, the message will be queued so that it can be sent again later by the checking routine. After completion of the checking routine, the timer is reset so that it may be invoked again after a fixed period of time.

Besides handling application process messages, the MPU has a high-priority mailbox from which it reads system command messages from the IISS operator via the Monitor AP. For instance, the operator can request a list of all active APs on the MPUs cluster or request the shutdown of a particular application process. The system command message that requires the MPU to go into its final stage of operation, SHUTDOWN, is a "SHUTDOWN AP CLUSTER" message from the operator via the Monitor AP.

The Shutdown stage of the Message Processing Unit operates basically like the Input Processing stage: messages are still processed by the MPU but in a different way. When the MPU received the "SHUTDOWN APC" message, it looks at each application process in the AP Status Table and, according to

each AP's characteristic, aborts the AP or informs it that it must shut itself down. The MPU then checks its mailboxes for a message from each of the APs that were told to shutdown. Only AP status messages and system commands from the Monitor AP (such as "CANCEL SHUTDOWN") are processed normally during the shutdown phase. All other types of messages are logged and ignored by the MPU. The MPU systematically checks to see if all the application processes on the cluster are dead. If no more messages are in the mailboxes to be processed and all the APs are no longer running, the MPU invokes its final shutdown processing. The AP Cluster initialization data is saved in a local file where it will be used during the next IISS or cluster startup. The MPU's input mailboxes are deleted and an "APC TERMINATING" message is sent to the Monitor AP. The Message Processing Unit then ends execution.

3.3 Interfaces

The Network Transaction Manager maintains communications with any other process through mailboxes. The mailboxes are managed by the Interprocess Communication Primitives (IPC's).

Communications with the remote computer is accomplished through the Communication sub-system process which will be running when there are other hosts to communicate with.

3.4 Program Interrupts

As mentioned previously, NTM is interrupt driven with interrupts coming either from the IPC's on behalf of any other process which may be another MPU or any other AP. Waiting for these interrupts is performed by one of the IPC wait primitives. If a response must be received within a particular time interval, the IPC's associated with timing are used along with one of the wait's.

3.5 Timing And Sequence Description

The NTM does not depend on any particular timing sequences.

3.6 Special Control Features

The Network Transaction Manager Subsystem does not include any special control features as defined in the ICAM Documentation Standards manual.

3.7 Storage Allocation

3.7.1 Data Base Definition - None.

3.7.1.1 File Description

NTM uses lots of files for table handling. This involves reading the initial values of the tables as well as using files for table overflow handling.

3.7.1.2 Table Description

The NTM Tables provide both static and dynamic data to the NTM MPU. The static data consists of configuration data, such as the location of an AP within the IISS, characteristics of a given AP, etc. The dynamic data consists of the run-time status of the NTM components, the IISS host machines, and the user's APs. There are currently fifteen NTM Tables. Their content is described in detail in the Development Specification.

3.7.1.3 Item and Constant Description

3.7.2 CPC Relationship

3.8 Object Code Creation

The generic portion of NTM is written in COBOL and 'C'. This has been successfully compiled on a VAX 11/780 under VMS, an IBM 3084 under MVS, and a Honeywell Level 6 under Mod 400.

The machine specific code of the NTM is written in COBOL. The different methods of handling files must be dealt with separately on each machine. This has been successfully compiled on a VAX 11/780 under VMS, an IBM 3084 under MVS, and a Honeywell Level 6 under Mod 400.

The minimum computer hardware and software required to create and run NTM in the IISS environment is documented in the Installation Guide for IISS on the VAX and in the Installation Guide for IISS on the IBM.

3.9 Adaption Data

In order to tailor NTM to either the VAX or the IBM, there are a few system dependent files required. For example, the table file handlers would have to be tailored to the particular machine you are on.

The command procedures to the create NTM executables are specific to each computer and can be found under Software Configuration Management.

3.10 Detail Design Description

The upcoming program details were derived from all modules that were selected when the following Documentation Group(s) was chosen:

NTMMPU

3.10.1 Main Program List

The following is a list of all "Main Programs" which are modules that are not called by any other module being documented here. These modules are either program entry points or, if they are hooked into another set of programs via subroutine calls, they are the points the external programs can call and therefore enter through. To differentiate between the two types of entry points, look at the individual Module Documentation (section 3.10.8) and look at Module Type for each of the Main Program modules listed. Note whether the routine is a Program, Subroutine, or Function. If it is a Program, it is truly a main program entry point. If not, then it is merely called by other programs not being documented here.

3.10.4 Include File List

The following is a list of all include files called in by modules being documented here. Each include file has a unique name regardless of the language being used. The purpose of each include file is listed as well. A more complete description of each include file is given in section 3.10.9. The purpose listed is the one that is in the source code of the include file.

A purpose of "**** PURPOSE NOT FOUND BY STRIPPER ****" indicates that a purpose statement was not written into the include file itself. The most common reason for this is that the include file comes from system libraries that were not developed by the project, such as 'C' libraries that are provided with the 'C' compiler.

See section 3.10.6 for a set of lists which show all the modules which call in each of these include files.

3.10.7 Main Program Parts List

The following lists each Main Program listed in 3.10.1 and all the modules which are called either by that module itself or by any of the documented modules which it calls. It is possible for a non-main module to be listed more than once if it is called by multiple modules. The called modules, in this case known as program parts, are marked as to whether they are documented here. If so, the phrase "well-defined module" appears by the module name, if not it is an "external routine". The Purpose of the Main Program module is listed as well.

3.10.8 Module Documentation

The following documentation describes information which is specific to each individual module being documented in this specification as listed in section 3.10.2. It provides a compact way of getting information that would be otherwise buried within each module's source code.

The specific items in this module documentation have the following meanings:

NAME:	Name of program Module.
PURPOSE:	Purpose of Module as detailed in the source code.
LANGUAGE:	Programming language source code is written in. The choices are: VAX-11 FORTRAN C (I/S-1 Workbench 'C') VAX-11 COBOL
MODULE TYPE:	Whether a Program, Subroutine, or Function.
SOURCE FILE:	Name of Source File from file specification.
SOURCE FILE TYPE:	Source File Extension from file specification.
HOST:	Whether this is a host-dependent routine (VAX or IBM) or blank if host-independent.
SUBSYSTEM:	IISS sub-system this file resides in.
SUBDIRECTORY:	Sub-directory of that subsystem in which this file resides.
DOCUMENTATION GROUP:	Name of documentation group of which this source file is a member.
DESCRIPTION:	A description of the module as obtained from the source code.
ARGUMENTS:	The arguments with which this routine is called if it is a Subroutine or a Function.
INCLUDE FILES:	A list of all the files that are included into this module as well as their purposes.

ROUTINES CALLED: Subroutines or Functions, either documented or external, called by this module, if any.

CALLED DIRECTLY BY: The documented routines which call this module, if any.

USED IN MAIN PROGRAM(S): The documented Main Programs which contain this module in their parts list according to the list in section 3.10.7.

The Module Documentation is arranged alphabetically according to Module Name.

DESCRIPTION:

- PROCESS AN AP DYING MESSAGE BY UP-
DATING THE AP STATUS TABLE. IF NOT IN THE
IISS SHUTDOWN MODE AND THE AP'S KIDS ARE DEAD
AND THE AP IS NOT IT'S OWN PARENT(SOME UI APS)
THEN SEND A CHILD STATUS MESSAGE TO THE PARENT.
IF THE AP IS IT'S OWN PARENT THEN CALL 'CLNUP'
TO DELETE THE AP STATUS ENTRY. THE INSTANCE
COUNT IS ALSO DECREMENTED AND THE AP OPERATING
TABLE IS UPDATED. FINALLY, THE WAIT-INIT
QUEUE IS CHECKED FOR AN INIT MESSAGE AWAITING
A FREE INSTANCE SO IT CAN BE PROCESSED. IF IN
SHUTDOWN MODE, 'SEARCH-START-FLG ALDEAD' IS
CALLED TO DETERMINE IF THE DEAD AP WAS THE LAST
TO DIE ON THE APC.

DESCRIPTION:

- AP STATUS TABLE IS CHECKD TO SEE IF ANY
INSTANCES OF THE AP ALREADY EXIST WITH THE STATUS
"AWAITING INIT". IF ONE IS FOUND THEN THE AWAIT INIT
IS PROCESSED, OTHERWISE THE AP INFO TABLE IS ACCESSED TO
ATTAIN THE NUMBER OF INSTANCES ALREADY INITIATED.

DESCRIPTION:

- PRCONC PROCESSES MESSAGES IF THEY ARE FROM ON THE APC. MESSAGES WITH NEW HEADERS THAT ARE NOT SENT BY THE MPU HAVE THEIR MSG CATEGORIES VERIFIED. IF THE CATEGORY IS VALID, THE MESSAGE IS AUTHORIZED AND THE MESSAGE HEADER IS COMPLETED. CERTAIN MESSAGES HAVE SPECIAL TABLE PROCESSING DONE SUCH AS PAIRED MESSAGES, INIT MESSAGES AND GUARANTEED DELIVERY MESSAGES. IF AT ANY POINT A MESSAGE ERROR OCCURS, A MESSAGE "NACK" IS SENT TO THE SOURCE OF THE MESSAGE OTHERWISE AN ACK IS SENT (UNDER CERTAIN CONDITIONS) AND A SERIAL NUMBER IS ATTACHED TO THE MESSAGE. IF THE MESSAGE HAS AN OLD HEADER OR IS FROM THE MPU, THE MPU SIMPLY ATTACHES A SERIAL NUMBER TO IT AND ALL OTHER VERIFICATION IS BY-PASSED.

DESCRIPTION: -----

- IF APC IS NOT IN A SHUTDOWN MODE, THE MPU WILL WAIT ON EVENTS AND HANDLE THE APC INPUT. THREE EVENTS ARE WAITED FOR: TIME TIMEOUT, MSG IN HI-PRIORITY MBX AND LOW-PRIORITY MBX. WHEN A MBX EVENT TAKES PLACE, THE MSG IS READ AND PROCESSED VIA MANAGE MESSAGE AND THEN (IF NO ERROR) THE MSG IS ROUTED AND SENT. IF THE TIMER EVENT TAKES PLACE, A PROCESS IS CALLED TO CHECK THE CERTAIN QUEUES AND TABLES FOR CERTAIN CONDITIONS. IF THE APC IS IN A SHUTDOWN MODE, EVENTS ARE NOT WAITED FOR BUT THE MBXS ARE CHECKED FOR MSGS. THE MSGS ARE READ AND PROCESSED BY A SPECIAL "SHUTDOWN MODE" PROCESS. ONLY AP STATUS MSGS AND SYSTEM COMMANDS WILL GO ON TO BE PROCESSED BY MM AND ROUTE & SEND.

DESCRIPTION:

- THERE ARE 3 TYPES OF SHUTDOWN THAT CAUSE AN APC TO SHUTDOWN --- APC SD, IISS SD AND HOST SD. IN ALL CASES, EACH AP IN THE CLUSTER IS SD ACCORDING TO ITS CHARACTERISTIC SHUTDOWN PROCEDURE--- ABORTED OR SENT A SOFT SD MSG. FOR EACH AP SD ON THE APC, ITS PARENT'S APC STATUS IS CHECKED. IF THE PARENT'S APC IS NOT IN A SD MODE, A CHILD STATUS MSG IS SENT TO THE PARENT'S MPU INFORMING THAT THE CHILD WAS SHUTDOWN. IF THE PARENT'S APC IS IN A SD MODE, THEN THE CHILD'S WILL PERFORM ITS OWN CLEANUP (WITHOUT CLEANUP MSG FROM PARENT'S MPU) AND SD MSGS WILL ALSO BE SENT TO THE AP'S OWN CHILDREN.

3.10.10 Hierarchy Chart

The following hierarchy charts show the relationships between all of the modules mentioned in the above documentation. A module may call a subroutine several times within its code, but the call will only be shown once as a single relationship on this hierarchy chart. All modules shown at the top of the first page are considered Main Programs as described in section 3.10.1 above.

There is an internal paging scheme as marked by the numbers in the upper right corner of each page. An index after the last page of the chart shows where a routine and its calls are first defined. If a routine has no page reference, it either makes no calls or is an external routine. A continuation box on the end of a tree limb shows where that the tree continues on the page number mentioned. A number in a box with a routine name points to the page where the routine is further defined within the hierarchy tree. If there is no number in a box, the routine either makes no calls or is an external routine.

SECTION 4

QUALITY ASSURANCE PROVISIONS

4.1 Introduction and Definitions

"Testing" is a systematic process that may be preplanned and explicitly stated. Test techniques and procedures may be defined in advance and a sequence of test steps may be specified. "Debugging" is the process of isolation and correction of the cause of an error.

"Antibugging" is defined as the philosophy of writing programs in such a way as to make bugs less likely to occur and when they do occur, to make them more noticeable to the programmer and the user. In other words, as much error checking as is practical and possible in each routine should be performed.

4.2 Computer Programming Test and Evaluation

The quality assurance provisions for test consists of the normal testing techniques that are accomplished during the construction process. They consist of design and code walk-throughs, unit testing, and integration testing. These tests are performed by the design team. Structured design, design walk-through and the incorporation of "antibugging" facilitate this testing by exposing and addressing problem areas before they become coded "bugs".
