ASSESSING HEARING PROTECTOR DEVICE PERFORMANCE AND CALCULATING ALLOWABLE EXPOSURE DURATIONS IN HAZARDOUS NOISE

INTRODUCTION

Purpose

This report reviews procedures used by base-level bioenvironmental engineering services (BES) to determine appropriate personal hearing protection devices (HPDs) and to calculate allowable exposure times for individuals wearing different HPDs in hazardous noise. Limitations of these procedures are discussed, and a preferred method is presented.

Problem

The use of HPDs is the primary method used in the Air Force to protect individuals from hazardous noise exposure because of the inability to control noise emissions from aircraft engines. However, for environments where noise levels exceed 118 dB(A) for equivalent 8-hour exposures, even combinations of HPDs will not provide adequate attenuation for workers. Time limits must be used in addition to HPDs in such conditions. BES personnel have expressed difficulty in calculating the amount of time an individual can be exposed to noise while wearing various protectors, and workers have difficulty performing assigned tasks within assigned time limits.

Scope

This report outlines procedures currently used by many BES personnel for selection of HPDs and allowable noise exposure times using the tables in Air Force Regulation (AFR) 161-35. It then presents a preferred method using computer analysis of noise dosimetry time histories. This method has the potential for increasing allowable exposure times, which would reduce operational restrictions for workplaces such as jet engine test cells. This report does not address the problems associated with wearing dual HPDs during Chemical Warfare Task Qualification Training. This issue was addressed in a consultative letter (AL-CL-1992-0015)(5).

DISCUSSION

Current Method

BES is responsible for determining the appropriate hearing protection for the specific noise exposure. This is accomplished through the use of noise

level surveys. The initial survey identifies sources of hazardous noise (those ≥ 84 dB(A)) by recording A-weighted and C-weighted levels on the DD Form 2214, Noise Survey. Levels are either measured directly, using a sound level meter, or copied from appropriate volumes of the USAF Bioenvironmental Noise Data Handbooks. BES personnel typically use the HPD selection blocks on the DD Form 2214 to determine levels of protection required instead of comparing the frequency characteristics of the noise source against the performance of each HPD used. When using the DD Form 2214, single protection is required for noise sources ≥ 84 dB(A), double protection (plugs and muffs) for noise sources ≥ 108 dB(A), and double protection and time limits for sources >118 dB(A). HPD performance is used for the time limit calculation. HPD attenuation is dependent on the frequency content of the noise source and is listed in AFR 161-35, Table 3, as a function of the noise source's C-weighted sound level minus the A-weighted level (the "C-A" value). The effective at-the-ear sound level is calculated by subtracting the HPD's noise attenuation value from the source's A-weighted sound level. This effective exposure level is used to calculate the allowable exposure time from AFR 161-35, Table 5.

Noise dosimetry is also conducted by BES to measure the average daily noise exposure (Lavg) of workers. Most models of personal noise dosimeters in use by the Air Force offer a time history capability which allows a minute-by-minute look at the worker's noise exposure over the course of the duty day. While noise dosimetry is used extensively to decide whether or not to place workers on monitoring audiometry, it has not been used to determine effectiveness of HPDs.

Preferred Method

The preferred method that follows is a new procedure for calculating the effective noise attenuation of HPDs and allowable exposure times for the effective at-the-ear noise levels. Instead of using a single A-weighted noise level for a noise source at the operator's position, or the highest value at any position and power setting, it uses the average of the 1-minute noise levels from a noise dosimeter's time history. Using the time history allows us to account for lower noise levels when the worker is away from the loudest position or when the engine is at lower power settings. This method provides a more realistic value for a worker's noise exposure while wearing HPDs. The noise dosimeter time history shows, within 1 minute, how much time during the day the worker was exposed ≥ 84 dB(A). We can also calculate the average exposure level and exposure duration for specific operations.

To illustrate the application of the preferred method, let's examine the noise exposures of a worker at the leak check position on the F-4 aircraft positioned in a noise suppressor. The expected sound level (from Table 2, Volume 131 of the Noise Data Handbooks)(7) will range from 107 dB(A) at idle to 124 dB(A) at afterburner. Engine trim run operations can be identified in the noise dosimeter time history by selecting consecutive time intervals which are in the range 107 - 124 dB(A). There may be three or four separate engine runs during the day which can be easily identified in the time history.

Summing all the consecutive time intervals in the time history which have corresponding noise levels in the selected range will tell us precisely how long each day this worker is exposed to engine trim run noise. The software allows us to recalculate the average noise exposure level for engine trim runs alone. This average exposure level to the actual operation is the value which should be used to evaluate the hearing protection effectiveness.

Data Management Procedures and Software

The mechanics of analyzing noise dosimetry data using this preferred method are labor intensive when manually calculated. Analysis is simplified when data management procedures, developed by the Noise Hazards Function, AL/OEMI, are followed and noise dosimetry data is electronically filed. These procedures involve using ENABLE software to download the noise dosimeter time history reports to computer disk files (4). Ideally, a computer program would use A-weighted and C-weighted time history data collected simultaneously and calculate the frequency dependent performance of HPDs from these time histories; however, at the time of the analysis in this report, there was no method available to collect A-weighted and C-weighted time histories concurrently. Later electronic circuitry developments by Metrosonics, Inc. will allow this simultaneously recording (5) with an increased refinement in HPD assessments. These enhanced procedures will be available soon on the Electronic Information Exchange System (EIES)(6), Brooks Air Force Base, TX, by dialing toll free 1-800-288-0726 anywhere in the CONUS, Alaska, Hawaii, Puerto Rico and the Virgin Islands or (512) 536-3784. It will also be available on diskette through requests to the Noise Hazards Function, AL/OEMI at DSN 240-3214.

If you do not have the capability of simultaneously recording A-weighted and C-weighted time histories, you must be certain to collect the A-weighted and C-weighted values together (i.e., from the same sound level meter survey at the same measurement location). A wide range of C-A values can be obtained depending on where both the A-weighted and C-weighted noise levels are obtained. In selecting the appropriate HPD attenuation, the C-A value should be selected from the lowest C-A values (worst performance) from the DD Form 2214 or the Noise Data Handbooks; however, it is important to note that more than one single number attenuation value can be determined from the DD Form 2214. Table 1 illustrates the method used to determine the two C-A values used to analyze the time history data for personnel wearing the modified H-133 communication headset. We consider the C-A value for engine RPM at 100% and afterburner more important for this operation because of the overall higher noise levels present at these power settings.

Table 1. Single Number Attenuation Factors for the
Modified H-133 Communications Headset

Engine Power Setting and Operator Location	Noise Level		C-A	Single Number Attenuation Factor (dBA)
	dB(C)	dB(A)		
1 Engine @ Idle 65%	104	102	2	29
1 Engine @ Mil Pwr 95%	124	124	0	31
1 Engine @ 100% & AB*	126	129	-3	31
Operator Position @ AB*	132	132	0	31

* AB = Afterburner

Example of Preferred Method

We illustrate the usefulness of this method with an actual consult from an Air National Guard Base which required wearing plugs and muffs and limited exposures to 1-hour maximum per day during RF-4C engine trims. The base BES supplied A-weighted and C-weighted sound level readings on the DD Form 2214 and a copy of A-weighted noise dosimetry time history data (Appendix A).

The time history report recorded on 24 Apr 90 was the worst exposure day (Lavg = 113.1 dB(A)) for the 5 days of monitoring (Appendix D, AF Form 2756). We selected this exposure because the selection of hearing protection should be based on the worst exposure day to ensure the greatest protection. We analyzed the dosimetry in two ways: analysis of only those time history intervals ≥ 84 dB(A) and analysis of intervals for specific source exposures. Each analysis was accomplished using both C-A values determined from the DD Form 2214.

Analysis of Intervals ≥ 84 dB(A)

Analysis of only those time history intervals ≥ 84 dB(A) is presented in Appendix B. The analysis was first performed by identifying those intervals with levels ≥ 84 dB(A) with an "X" in the flag column. The software program identified a total exposure time of 157.0 minutes from these flagged intervals, with an average sound exposure level of 119.6 dB(A) for the 157.0 minutes. The allowed exposure time was calculated using this data and the attenuation value for the H-133 modified headset in Table 3 - Single Number Attenuation Factors (dBA), in AFR 161-35, Hazardous Noise Exposure (1). The C-A attenuation factors were obtained using information on the DD Form 2214 supplied by the base (Table 1). Based on this worst case exposure, the maximum allowable exposure times for the modified H-133 were calculated. The individual's observed daily duration (ODD) of exposure of 157.0 minutes was divided by his limiting daily duration (LDD) for each C-A value to determine the fraction of his allowable daily exposure.

Table 2. Maximum Allowable Exposure Times
for Noise Levels ≥ 84 dB(A)

Hearing Protector	Single Number Attenuation Factor (dBA)	At-the-Ear Exposure (dBA)	Maximum Allowed Exposure Time (LDD, minutes)	Allowed Time Remaining (minutes)	Fraction of Allowable Exposure (ODD/LDD)
Modified H-133 Comm Headset	31	88.6	217.3	60.3	0.72
	29	90.6	153.6	-3.4	1.06

Analysis of Intervals for Specific Source Exposures

The second analysis identified time intervals for specific source exposures, in this case, engine trim runs identified in the time history by either "I" (engine RPM at idle) or ">" (engine RPM greater than idle) (Appendix C). Whenever specific noise operations can be identified, hearing protection can be more appropriately matched for that noise source. When noise levels for operations are not clearly identifiable from the time history alone, further information is needed. Video taping, note taking, and discussions with the shop supervisor or workers may be necessary to match the time history exposure to actual noise operations.

Four engine runs were completed on 24 Apr 90 for a total actual exposure time of 92 minutes. An average sound exposure level of 122.6 dB(A) was calculated for the 92 minutes of engine operation. The allowed exposure time was calculated using this data and the attenuation value for the H-133 modified headset in Table 3 - Single Number Attenuation Factors (dBA), in AFR 161-35, Hazardous Noise Exposure. The C-A attenuation factors were obtained using information on the DD Form 2214 supplied by the base (Table 1). Based on this worst case exposure, the maximum allowable exposure times for the modified H-133 were calculated. The individual's observed daily duration (ODD) of exposure of 92.0 minutes was divided by his limiting daily duration (LDD) for each C-A value to determine the fraction of his allowable daily exposure.

Table 3. Maximum Allowable Exposure Times
for Engine Runs

Hearing Protector	Single Number Attenuation Factor (dBA)	At-the-Ear Exposure (dBA)	Maximum Allowed Exposure Time (LDD, minutes)	Allowed Time Remaining (minutes)	Fraction of Allowable Exposure (ODD/LDD)
Modified H-133 Comm Headset	31	91.6	127.5	35.5	0.72
	29	93.6	90.2	-1.8	1.02

Based on total actual exposure time of 92.0 minutes per day with an allowed exposure time of 127.5 minutes per day, as calculated from the noise dosimetry data for the individual in the engine shop, we found their noise controls were overly restrictive. We recommended they eliminate their control of limiting exposures to a maximum of 1 hour per person per day. Based on the conditions in our example, there was sufficient time remaining for continued exposure before rotation of personnel was necessary. Should the actual exposure time increase beyond the 127.5 minutes of allowed exposure time, they must either 1) enforce the total allowed exposure time; 2) evaluate another hearing protection device; or 3) incorporate additional administrative controls.

Calculating Exposures to Multiple Operations

The amount of time an individual can spend exposed to multiple noise sources or operations depends on the noise levels and HPDs used for each operation. The effects of all operations in a work day can be calculated by adding the fraction of allowable exposure (ODD/LDD) for each operation, as outlined in AFR 161-35, paragraph 21.b., Calculating Limiting Values - Two or More Independent Exposures Each Workday. This states that daily noise exposures are within limits when the summed exposures do not exceed one (1.0). This is expressed mathematically as:

$$\text{ODD1/LDD1} + \text{ODD2/LDD2} + \text{ODD3/LDD3} + \dots + \text{ODDn/LDDn} \leq 1.0$$

CONCLUSIONS

- AFR 161-35 does not clearly describe a method for the BES to make an informed decision on the selection of appropriate hearing protection devices.
- A preferred method and computer program are presented which permits BES technicians to calculate allowable exposure times for individuals wearing various HPDs in hazardous noise environments.
- The mechanics of analyzing noise dosimetry data using this preferred method are labor intensive when manually calculated. The calculation of multiple C-A values from AF Forms 2214 presents a problem in deciding which factor is the most appropriate for determining the adequacy of the HPD. Analysis is simplified and more accurate when data management procedures, developed by the Noise Hazards Function, AL/OEMI, are followed and noise dosimetry data is electronically filed.
- This preferred method requires a software program designed for use with the noise dosimetry time history to calculate the allowed exposure time for individuals wearing various hearing protection devices. Recent developments in electronic circuitry have further enhanced the HPD assessment process by allowing the simultaneous recording of A-weighted and C-weighted time histories. This eliminates the multiple C-A values possible when using the DD Form 2214. This program will soon be available on the Electronic Information Exchange System (EIES) and on diskette through requests to the Noise Hazards Function, AL/OEMI.

- The selection of HPDs should be documented in the shop folders.
- Selection of the most appropriate HPD requires detailed knowledge of the noise environment which includes:
 - noise source levels (dB(A) and dB(C))
 - exposure duration
 - average exposure level dB(A)
 - time history exposure at 1-minute intervals matched to noise sources
- Since the definition of hazardous noise is based on exposure, we should use both the noise level and the duration of exposure to determine the adequacy of hearing protection and the allowable exposure limits. Time history noise dosimetry is the preferred method for estimating exposure. Sound level meter readings and Noise Data Handbooks are useful alternatives when time history dosimetry is not available.
- Using 1-minute time intervals provides adequate detail of how noise levels fluctuate for the workers during their duty day. This is the largest time interval recommended when applying the time history noise dosimetry data in the procedure for selecting or evaluating hearing protectors.
- Selection of hearing protection should be based on the worst exposure day to ensure greatest protection.
- Noise exposure data can be examined several different ways. Two ways given in this report were: all exposures ≥ 84 dB(A) (Appendix B) and specific source exposures (Appendix C).
- Whenever specific noise operations can be identified, hearing protection can be more appropriately matched for that noise source. We believe an average exposure level of the actual operation is the value which should be used to evaluate the effectiveness of hearing protection.

RECOMMENDATIONS

When HPDs and time limits are needed to control worker exposure to hazardous noise, use noise dosimetry time histories with the procedures described in this report to calculate the effectiveness of the HPDs and time limits.

Hearing Protection Assessment
Summary for Exposures
At or Above 84 dB (A)

**NOISE EXPOSURES (≥ 84 dB(A))
DURING SUPPRESSOR OPERATIONS USING THE H-133 HEADSET**

Subject.....: Jet Engine Test Shop
 Test Date.....: 04-24-1990
 Archive Date.....: 08-12-1991
 Analysis Date.....: 08-14-1991
 Dosimeter.....: Metrosonics db-310 SN 1146
 Noise Source.....: RF-4C at suppressor
 Hearing Protection Device.....: H-133 (mod w/custom molded insert)
 C-A Value.....: -2 thru 0
 Selected Noise Codes.....: X, I, >

Total Minutes Minus Exposure Time.....: 157.0 min
 Average Sound Exposure Level (4 dB).....: 119.6 dBA
 Attn from Hearing Protector.....: 31.0 dBA
 Effective at Ear Exposure.....: 88.6 dBA
 Total Allowed Exposure Time.....: 217.3 min (3.6 hrs)
 Allowed Time Minus Actual Exposure Time: 60.3 min *

Subject.....: Jet Engine Test Shop
 Test Date.....: 04-24-1990
 Archive Date.....: 08-12-1991
 Analysis Date.....: 08-14-1991
 Dosimeter.....: Metrosonics db-310 SN 1146
 Noise Source.....: RF-4C at suppressor
 Hearing Protection Device.....: H-133 (mod w/custom molded insert)
 C-A Value.....: 1 thru 3
 Selected Noise Codes.....: X, I, >

Total Minutes Minus Exposure Time.....: 157.0 min
 Average Sound Exposure Level (4 dB).....: 119.6 dBA
 Attn from Hearing Protector.....: 29.0 dBA
 Effective at Ear Exposure.....: 90.6 dBA
 Total Allowed Exposure Time.....: 153.6 min (2.6 hrs)
 Allowed Time Minus Actual Exposure Time: -3.4 min *

* All positive numbers represent adequate hearing protection (HP) attenuation values. Positive numbers represent the time remaining before the allowed exposure time is exceeded, and alternative controls are required. Negative numbers represent inadequate HP attenuation values. Negative numbers also represent the minutes the allowed exposure time is exceeded. If the number is negative you must either (1) enforce the total allowable exposure time, (2) evaluate another HPD, or (3) incorporate additional administrative controls.

APPENDIX C
Hearing Protection Assessment
Summary for Specific
Source Exposures

**NOISE EXPOSURES
FOR ENGINE TRIM OPERATIONS USING THE H-133 HEADSET**

Subject.....: Jet Engine Test Shop
 Test Date.....: 04-24-1990
 Archive Date.....: 08-12-1991
 Analysis Date.....: 08-14-1991
 Dosimeter.....: Metrosonics db-310 SN 1146
 Noise Source.....: RF-4C at suppressor
 Hearing Protection Device.....: H-133 (mod w/custom molded insert)
 C-A Value.....: -2 thru 0
 Selected Noise Codes.....: I, >

Total Minutes Minus Exposure Time.....: 92.0 min
 Average Sound Exposure Level (4 dB).....: 122.6 dBA
 Attn from Hearing Protector.....: 31.0 dBA
 Effective at Ear Exposure.....: 91.6 dBA
 Total Allowed Exposure Time.....: 127.5 min (2.1 hrs)
 Allowed Time Minus Actual Exposure Time: 35.5 min *

Subject.....: Jet Engine Test Shop
 Test Date.....: 04-24-1990
 Archive Date.....: 08-12-1991
 Analysis Date.....: 08-14-1991
 Dosimeter.....: Metrosonics db-310 SN 1146
 Noise Source.....: RF-4C at suppressor
 Hearing Protection Device.....: H-133 (mod w/custom molded insert)
 C-A Value.....: 1 thru 3
 Selected Noise Codes.....: I, >

Total Minutes Minus Exposure Time.....: 92.0 min
 Average Sound Exposure Level (4 dB).....: 122.6 dBA
 Attn from Hearing Protector.....: 29.0 dBA
 Effective at Ear Exposure.....: 93.6 dBA
 Total Allowed Exposure Time.....: 90.2 min (1.5 hrs)
 Allowed Time Minus Actual Exposure Time: -1.8 min *

* All positive numbers represent adequate hearing protection (HP) attenuation values. Positive numbers represent the time remaining before the allowed exposure time is exceeded, and alternative controls are required. Negative numbers represent inadequate HP attenuation values. Negative numbers also represent the minutes the allowed exposure time is exceeded. If the number is negative you must either (1) enforce the total allowable exposure time, (2) evaluate another HPD, or (3) incorporate additional administrative controls.
