13. Abstract (maximum 200 words) The Rickenbacker Air National Guard Base is located 12 miles southeast of Columbus, Ohio. Engineering Science was contracted to perform an environmental field investigation at the hazardous waste storage area (HWSA) located on the base. Portions of the HWSA have been used over the past 42 years for the storage of waste oils, waste fuels, deicing fluid and various solvents and cleaners. The materials stored at the HWSA were contained in either storage drums, or in the four 25,000 gallon underground storage tanks. The purpose of the investigation was to determine if the soil or ground water beneath the site have been contaminated due to spills or leak from the on-site storage. Contamination was confirmed at the site and additional investigations were recommended to define the lateral and vertical extent and magnitude of contamination

SECTION 1.0

EXECUTIVE SUMMARY

The Rickenbacker Air National Guard Base (RANGB) is located 12 miles southeast of Columbus, Ohio. Engineering-Science (ES) was contracted to perform an environmental field investigation at the Hazardous Waste Storage Area (HWSA) located on the Base. Portions of the HWSA have been used over the past 39 years for the storage of waste oils, waste fuels, de-icing fluid and various solvents and cleaners. The materials stored at the HWSA were contained in either storage drums, or in the four 25,000 gallon underground storage tanks located at the site. The purpose of the field investigation was to determine if the soil or groundwater beneath the site have been contaminated due to spills or leaks from the on-site storage.

The scope of work for the field investigation consisted of surface soil sampling, soil-gas surveying, hand and auger borings, installation of three groundwater monitoring wells, and aquifer testing. Soil and groundwater samples were collected and analyzed for both organic and inorganic compounds.

The findings of the drilling program indicate the geologic profile beneath the HWSA consists of silty clay (0-14.5') underlain by sand and gravel to the end of boring at 20 feet. The Base water wells indicate that two aquifers are present in the glacial material beneath the Base; a shallow (3-35' below land surface) and deep (60-200' below land surface) aquifer. The depth to the shallow aquifer beneath the HWSA is approximately eight feet subgrade, while the groundwater flow direction is to the east.

The results of the soil and groundwater analyses are summarized below:

- Semi-volatile organic compounds (up to 37.9 mg/kg) and abnormally high metal concentrations were detected in the shallow soils at the site.
- Petroleum hydrocarbons in the form of benzene, ethylbenzene and xylenes are present in the soil (MW1: 32.9 mg/kg) and groundwater (MW1: 116 µg/l) beneath the site. The concentration of benzene (94 µg/l) measured in the groundwater from monitoring well MW1 exceeded the Federal drinking water Maximum Contaminant Level (MCL) by a factor of 18.8. The areal extent of the contamination has not been defined.
- Trichloroethylene was detected in the groundwater collected from monitoring well MW3 (44 µg/l). This TCE concentration exceeds the Federal drinking water MCL by a factor of 8.8.

- The total metal concentrations in the groundwater from each of the three monitoring wells exceeded the drinking water standards for arsenic, cadmium, chromium and lead. It is not known whether the metal concentrations were dissolved in the groundwater or present on suspended sediments.

Additional investigation of the HWSA is necessary to define the vertical and horizontal extent of volatile and semi-volatile organic compounds and metals in the soil and groundwater. The investigation activities should include surface soil sampling, soil sampling from borings and groundwater sampling from monitoring wells.

SECTION 2.0

BACKGROUND

2.1 BASE BACKGROUND

The U.S. Department of Defense (DOD) has initiated the Installation Restoration Program (IRP) to identify, evaluate, and remediate suspected environmental problems associated with past hazardous waste disposal and spill sites on DOD facilities. The Air National Guard (ANG), through a U.S. Air Force (USAF) interagency technical support agreement with the U.S. Department of Energy (DOE), uses Martin Marietta Energy Systems, Inc. (MMES) to provide technical assistance for implementation of the ANG IRP. Martin Marietta Energy Systems, Inc., has been contracted by DOE to carry out the Hazardous Waste Remedial Actions Program (HAZWRAP) at Air National Guard Bases. Engineering-Science (ES) as a subcontractor to HAZWRAP conducted the soil and groundwater sampling documented in this report. Authorization for the investigation is by General Order No. 18B-97387C, Task Order X-15.

The Rickenbacker Air National Guard Base (RANGB) is located 12 miles southeast of Columbus, Ohio and 0.5 miles east of the Village of Lockbourne, Ohio (Figure 2.1). The Base was known as Lockbourne Air Force Base until 1974. The current size of the Base is approximately 2,100 acres. The Base operations are managed by the Ohio Air National Guard. However, the Rickenbacker Port Authority (RPA) acquired a portion of the Base in 1982 which serves private aircraft, and as a base of operations for the Flying Tigers air delivery service. The Flying Tigers will be leaving the Base in the autumn of 1989. At one time, as many as 5,000 people have worked on the Base. Currently, 1,100 people are on the Base daily.

Land use adjacent to the Base is residential and agricultural. The houses and apartments in the northwest corner of the Base, which were formerly occupied by Base personnel, have been purchased by a private developer and are being rented and sold. The Base and former Base housing use water supplied from Base water wells.

North of the Base lies open agricultural land with some residential development along Alum Creek Drive. East of the Base is agricultural land and residential development along the major roads. South of the Base is the former Base golf course which is now privately-owned, and widely spaced single-family homes. To the west is the

Future land use in adjacent areas will probably be residential and light industrial as the urban growth of Columbus extends to the southeast.

2.2 HAZARDOUS WASTE STORAGE AREA

The Hazardous Waste Storage Area at the RANGB consists of Building 560 and the Drum Storage Area to the southeast of the building (Figure 2.2). Table 2.1 is a legend for the various utilities shown on the site maps. The site had been operating under and interim hazardous waste storage area permit since 1983. There are four, steel 25,000 gallon underground storage tanks (USTs) beneath the site that are approximately 39 years old. Two of the tanks are actively being used for the storage of de-icing fluid. The two inactive tanks had previously been used for the storage of used oil and recyclable JP-4 fuel. Dielectric fluid drained from transformers had also been stored in the used oil UST. It is not known if the fluid contained PCBs. The used oil and JP-4 fuel tanks became inactive in the latter part of 1988. Present contents of the tank are unknown. The only recorded loss from any of the four tanks occurred in 1982 from a broken stand pipe. A precise record of the amount of waste released is not available.

The Drum Storage Area had been used to store drums containing liquid wastes such as spent solvents, cleaning fluids, acids and paint strippers. Dry wastes such as spent desiccants were also stored in Building 560. No wastes are currently being stopped at the site.

SECTION 3.0

PURPOSE AND SCOPE

The purpose of the investigation at the Hazardous Waste Storage Area was to determine if the soil or groundwater beneath the site have been contaminated due to spills or leaks from the on-site storage. This objective was accomplished through the following investigative techniques.

- A soil-gas survey was utilized as a reconnaissance tool to aid in the placement of monitoring wells.
- Soil samples were collected from the surface and during monitoring well installation. Laboratory analyses of the soil samples determined whether contaminants were present in the soil.
- Monitoring wells were installed to test for the presence or absence of phase-separated hydrocarbons, determine the direction of groundwater flow, and to collect groundwater samples for laboratory analysis.
- Aquifer tests (rising-head tests) were conducted on each of the monitoring wells to determine the aquifer hydraulic conductivity.

SECTION 4.0

ENVIRONMENTAL SETTING

The environmental setting of Rickenbacker ANGB is described in this Section with the primary emphasis directed toward identifying features that may affect the movement of hazardous waste contaminants off-base.

4.1 CLIMATE

The climate of Columbus, Ohio is characterized as continental (Pierce, 1959). The mean annual temperature is 52°F. The coldest month is January, while the warmest month is July with mean temperatures of 30°F and 74°F, respectively. Mean annual precipitation is 38 inches with October being the driest and June the wettest months. Net precipitation is calculated to be 2.71 inches per year (HMTC, 1987).

4.2 SOILS

Soils mapped at the Base are of the Kokomo and Crosby Series (SCS, 1976). The soils are characterized as deep, very poorly drained, slowly to moderately slowly, permeable soils formed in glacial tills on uplands. The Crosby series soils are formed on slopes up to 6 percent grade while the Kokomo series soils form on gentler, 0-2 percent, slopes on the higher landscape positions. The Crosby soils exhibit permeabilities of 0.06 in/hr (4.23×10^{-5} cm/sec) in unleached horizons. The Kokomo soils have permeabilities of 0.2 to 2.0 in/hr (1.4×10^{-4} to 1.4×10^{-3} cm/sec).

4.3 SURFACE WATER HYDROLOGY

Rickenbacker ANGB occupies the drainage divide between Big Walnut Creek and Walnut Creek. Surface drainage from the Base is through an extensive storm drain network which includes corrugated metal and concrete drainage pipes and open drainage ditches. All of the surface water is routed through oil-water separators before release into surrounding surface streams. Figure 4.1 is a map illustrating the boundaries of the surface water drainage basins on the Base.

DRAINAGE AREAS
RICKENBACKER ANGB, OHIO

4.4 REGIONAL GEOLOGY

The Base is located in the Glaciated Central Lowlands Province just west of the Appalachian Plateau Province. The geology of the area is characterized by 200 feet ($\pm$) of Pleistocene glacial outwash (sand and gravel), and silty and clayey till filling a preglacial bedrock valley (Smith and Goldthwaite, 1958). The bedrock types under the mixed drift fill are Devonian limestones and shales of the Columbus and Delaware Formations.

4.5 LOCAL HYDROGEOLOGY

The local hydrogeology in the vicinity of the Base was studied from data collected during the drilling operations of this investigation, and from reviewing local water well records. Local well records included well logs from five of the Base water wells, and well logs from eighteen domestic wells located in the vicinity of the Base. After reviewing the data and records listed above, it was determined that two aquifers are present in the glacial material beneath the Base.

The shallow geology beneath the Base is comprised of 10-20 feet of silt and clay at the surface, underlain by intermittent stringers and lenses of sand and gravel ranging in thickness from 1-10 feet. The depth to the shallow aquifer ranges from 3-20 feet, while the depth to the base of the aquifer ranges from 30-35 feet. The direction of groundwater flow in the shallow aquifer is affected by both the Big Walnut Creek to the west and the Walnut Creek to the east. The Base is within a recharge area of the shallow aquifer with groundwater flow to the west, south or east depending on where you are located.

The geologic material separating the shallow and deep aquifers beneath the Base consists of 30 to 40 feet of silty clay. The deep aquifer consists of fine-to-medium sand and gravel at a subsurface depth of approximately 50-60 feet. The bottom of the deep aquifer was defined in several of the Base water wells which encountered shale at an approximate depth of 200-210 feet beneath the surface.

4.6 LOCAL GROUNDWATER USE

There are seven water supply wells located on the Base. Five of the wells are located in the northwest portion of the Base and supply the drinking water for ANGB

personnel. Of the five drinking water wells, well #2 is no longer in service. The depth of the active ANGB drinking water wells ranges from 201 to 232 feet. The wells are screened in the glacial sands and gravels immediately above the shale bedrock. Static water levels in the drinking water wells range from 36 to 56 feet below grade. The two other water wells located on the Base are found at the heating plant, and at the golf course clubhouse in the southeast corner of the Base. The heating plant well (RB-7) was screened in sand and gravel from 85 to 100 feet beneath the surface, but is no longer in service. The clubhouse well (RB-6) was screened in sand and gravel from 63 to 73 feet beneath the surface.

Drillers' logs were obtained from the Ohio Department of Natural Resources (ODNR) for domestic water wells in the vicinity of the ANGB. Copies of the drilling records are submitted in Appendix A. Figure 4.2 is a map illustrating the locations of the domestic water wells, and the five active wells on the ANGB. The domestic wells in the Village of Lockbourne are not shown on the map because they are no longer in service. The Village currently receives water from the Base water system. Table 4.1 lists pertinent well data for those wells shown on Figure 4.2. As shown in Table 4.1, the local domestic wells are screened at various depths ranging from 24 to 172 feet.

4.7 SIGNIFICANCE OF ENVIRONMENTAL SETTING

The significance of the environmental setting when dealing with potential contaminants is determining if the setting will promote or inhibit the vertical and lateral migration of contaminants from the source area. This subsection discusses how the environmental setting at Rickenbacker ANGB will affect the migration of contaminants on and beneath the HWSA.

The geologic material in the first ten feet beneath the surface generally controls contaminant migration. At the HWSA, the soils present from 0-10 feet beneath the surface almost exclusively consisted of silty clays. This material has very low vertical and horizontal permeability, and would thus inhibit both the vertical and horizontal migration of contaminants. This is significant in that it vastly decreases the probability of contaminants spilled at the surface will reach the groundwater. However, contaminants released from USTs, will be more likely to impact the groundwater. Groundwater contamination is typically the main mode of transport for off-site migration of contaminants.

-- Indicates that information was not available

There are two aquifers beneath the Base as discussed in Section 4.5. The shallow aquifer (8-32' below land surface), and the deep aquifer (64'-200' + below land surface). As shown on Table 4.1, the local water supply wells are completed almost exclusively in the deep aquifer. As mentioned, the low permeability of the soil profile would reduce the probability of significant contamination reaching the shallow aquifer. Therefore, the probability of contaminants reaching the deep aquifer would be very low. However, the deep aquifer has not been sampled at this time.

SECTION 5.0

FIELD INVESTIGATION PROGRAM

The field investigation program conducted at the hazardous waste storage area consisted of several investigative techniques. This Section describes the methodology and construction specifications utilized during the investigation. The decontamination procedures, sample numbering method, and the sample packaging, shipping and handling techniques are described in Appendix B.

5.1 METHODOLOGY

5.1.1 Surface Soil and Shallow Boring Sampling

The purpose of surface soil and shallow boring sampling was to determine the presence and extent of contamination in the upper soil horizons. The shallow sampling methods were utilized to determine whether surface spills had occurred at the site, related to the storage of drums.

Surface soil samples were collected using a stainless steel trowel. Shallow boring samples were collected using either a hand auger or a driven split-spoon sampler. The HB prefix was retained to simplify identification of the samples. The shallow boring samples were collected down to a depth of four feet. Each four-foot boring was divided into three discrete-depth samples (SS1: 0-1.3'; SS2: 1.3-2.6'; SS3: 2.6-3.9'). Soil samples collected for volatile organic analysis were placed in jars as quickly as possible to minimize the loss of volatile organic compounds. The remainder of the sample was thoroughly mixed in a stainless steel bowl before filling the remaining sample jars.

5.1.2 Soil-Gas Surveying

The soil gas survey was used as a field reconnaissance tool in which shallow (2-10' deep) soil vapor samples were collected for immediate on-site chemical analysis of volatile organic compounds which are associated with surface and subsurface spills or leaks. The chemical analysis data were used to construct contour maps of contaminant vapor concentrations in the unsaturated zone. The contour maps then assisted in planning field activities for the placement of soil borings and monitoring wells.

The soil vapors were analyzed with a Photovac 10S50 portable gas chromatograph (GC) which utilizes a photoionization detector (PID) with a 10.6 eV light source and isothermal capillary column with a precolumn/backflush configuration. The GC was calibrated with a 1 ppm commercially prepared mixture containing benzene, toluene and ortho-xylene (BTX). These standard compounds were chosen since they are commonly associated with the reported spills and leaks at the Base. Because of the screening nature of the soil-gas survey, only the BTX compounds were quantified.

The GC compares the response of injected volumes of unknown soil vapor samples with the response of the standard, and then integrates and quantitates the peak.

An electric hammer drill was used to drive a 3/8 inch, hollow stainless steel probe (perforated on the down-hole end) into the ground to the desired sampling depth. A vacuum pump was then used to draw soil vapors from the probe into a vacuum chamber containing a 1 liter Tedlar sample bag. Prior to collecting each sample, all probes, Teflon lines and stainless steel fittings that contacted soil vapors were decontaminated by rinsing with methanol and purging the system with compressed air for approximately 2 minutes.

A number of QA/QC procedures were followed during the course of the soil gas survey. Standard calibration checks were obtained during the initial and final runs of each day by injecting the standard gas mixture into the GC. Decontamination procedures were checked by injecting samples of ambient air that were passed through the sampling train and needles. If contamination was detected, the decontamination process was repeated until no contamination appeared. These types of blanks were done prior to each day's testing or when significant amounts of compounds were noted in a sample.

5.1.3 Soil Borings/Monitoring Wells

Three soil borings were drilled at the site using 4-inch ID/6 inch OD hollow-stem augers. Split-spoon samples were collected during drilling operations according to ASTM method D-1586. Soil samples were collected continuously during the drilling of MW1 and MW2, and at 3.5 foot intervals during the drilling of MW3.

Soil samples were classified with respect to type, by the visual-manual procedure (ASTM D-2488) noting mineralogy, color, odor, staining, etc. The samples were also checked for the presence of organic vapors. The test for vapors involved placing a

portion of the sample, not intended for volatile analysis at the laboratory, in a jar, sealing the jar, allowing the sample to equilibrate for at least five minutes, then measuring the concentration of organic vapors in the headspace of the jar using a meter with a PID.

Soil samples selected for chemical analysis for non-volatile constituents were removed from the sampler and split among the various containers for shipment to the laboratory. Samples for volatile analysis were placed in bottles as quickly as possible to minimize volatilization.

Monitoring wells were installed in each of the three borings using two inch diameter, 0.010 inch slot, Schedule 40 PVC well material. The screen and casing have threaded flush joints and a threaded bottom cap. Ten feet of screen was used in each well to allow for seasonal water level fluctuations. The screen and casing were installed through the inside of the augers. The annular space between the screen and borehole was filled with sand while the augers were slowly withdrawn. The sand pack extended two feet above the screen and a minimum two-foot thick bentonite seal was placed above the sand. The remaining annular space between the casing and borehole was filled with a cement/bentonite grout mixture. The well construction was completed 2-3 feet above-grade utilizing steel protective casing (six feet long) equipped with a locking cap. The protective casing was set into the cement grout 3-4 feet below land surface and a concrete pad (6 inches thick) was placed around the steel casing. Three steel guard posts were installed around each monitoring well for well security. Each well was permanently marked by attaching a metal plate that records the well number, drilling date, and top of casing elevation. Figure 5.1 is a diagram illustrating the typical monitoring well construction.

The wells were developed by air-lift pumping and bailing to remove the fine sediments in the vicinity of the well-bore. This procedure enhances the hydraulic connection between the well and aquifer. The wells were developed until the groundwater pH and conductivity had stabilized to ± 10 percent.

5.1.4 Groundwater Sampling

Each well was purged prior to sampling to ensure that a representative groundwater sample was obtained. The wells were purged by bailing until the total well water volume (TWWV) had been removed, the pH, conductivity and temperature had

FIGURE 5.1
TYPICAL MONITORING WELL CONSTRUCTION
 FOR SHALLOW AQUIFER WELLS
 RICKENBACKER ANGB, OHIO

stabilized, or until the well was dry. The TWWV includes water in the screen, riser and sand pack. The pH, conductivity, and temperature of the water were determined at least three times while purging the well.

The groundwater samples were collected with a Teflon bailer with a dedicated polypropylene line. The first sample withdrawn was put in a container for volatile analysis. The remaining water was then poured into other sample bottles. Appropriate preservatives were added to the sample bottles after sample collection. All samples were shipped overnight to an environmental laboratory for analysis. Shipping and handling procedures are documented in Appendix B.

5.1.5 Aquifer Testing

In-situ Hydraulic conductivity (permeability) tests utilizing the rising head slug test technique were conducted on each monitoring well. Water level recovery data were collected with a HERMIT data logger (Model SE 1000B) connected to a down-well pressure transducer.

Prior to testing, static water levels were measured in each monitoring well with an electronic water level indicator. The transducer for the HERMIT data logger was inserted into each well to a depth of at least 5 feet below the static water level. A PVC bailer (5 ft. in length and 1.5 in. inside diameter) was then inserted and completely submerged in the well above the transducer. The water level in the well was allowed to return to the original static level.

Prior to initiation of the test, the static water level was remeasured with a water level indicator. The water level was entered into the data logger as a reference value from which changes in head over time during the test were measured. The data logger was then activated and the bailer containing water was quickly removed from the well.

During the test, water level changes in each well were checked periodically with an electronic water level indicator as a means of validating the transducer data. When water levels in each well approached the initial static level (within 0.1 ft.) recovery was determined to be complete and the test terminated.

5.2 SITE-SPECIFIC INVESTIGATION

Sampling began at this site on 14 June 1988 with the collection of surface soil and shallow soil boring samples. The surface soil samples were collected from the locations identified on Figure 5.2 to identify possible contamination from drum spillage. Adjacent samples were composited before being contained and shipped to the laboratory. A duplicate of the RB1-SU1 & 2-GS1 sample was submitted for analysis (Dup# RB1-SU17 & 18-GS1). The surface soil samples were analyzed for herbicides, pesticides, PCBs, semi-volatile organics, and priority pollutant metals.

Soil samples from shallow soil borings (Figure 5.2) were collected on 14 June and 6 July 1988. Except for HB2, HB3 and HB5, the samples were collected using a hand auger as described in Section 5.1.1. HB2 and HB3 were to be composited due to their proximity. However, because of gravelly soil, the auger could not be advanced beyond a depth of 1 ft in HB3, so only the shallow soil samples from each boring were composited and the two deeper HB2 soil samples were collected. Sampling of HB5 below two feet was not possible due to a concentration of gravel at that depth. Shallow soil boring samples and monitoring well soil samples were analyzed for volatile organics, semi-volatile organics, PCBs, pesticides and priority pollutant metals.

An initial monitoring well was installed near HB2 and HB3 (RB1-MW1, Figure 5.2) on 20 July 1988. Two soil samples with the highest headspace PID response were selected from the well boring for chemical analysis (RB1-MW1-SS1, 12-14' and RB1-MW1-SS2, 14-16').

A 9 point soil-gas survey was conducted in and around the site on 25 July 1988. Based on the soil-gas results, two additional monitoring wells (MW2 and MW3, Figure 5.2), were installed on 29 July and 10 August 1988, respectively. The two soil samples from each well boring with the highest headspace PID response were selected for chemical analysis (RB1-MW2-SS1, 0-4'; RB1-MW2-SS3, 4-6'; RB1-MW3-SS1, 0-2' and RB1-MW3-SS2, 5-7'). Duplicates of samples RB1-MW2-SS1 (Dup# RB1-MW2-SS2) and RB1-MW3-SS2 (Dup# RB1-MW3-SS3) were also submitted for analysis.

The three monitoring wells were developed by air-lift pumping and bailing. Fifty gallons of water were removed from RB1-MW1 on 8/12/88 using the pump. The slow recovery of RB1-MW3 required hand bailing development rather than pumping. Six gallons of water were removed over three days (bailed dry each day) ending on 8/17/88.

FIGURE 5.2
BORING, SURFACE SOIL SAMPLE
AND MONITORING WELL LOCATIONS
HAZARDOUS WASTE STORAGE AREA
RICKENBACKER ANGB, OHIO

Groundwater samples were collected from the monitoring wells on 19 and 22 September 1988. The groundwater was analyzed for the same constituents as the well boring soil samples. A duplicate water sample from RB1-MW1 was also submitted for analysis (Dup # RB30-MW1-GW1).

A repeat water sampling of MW3 was done on 17 October 1988 to replace samples contained in jars broken in a laboratory accident. The replacement samples were analyzed for semi-volatile organics, pesticides and PCBs.

In-situ hydraulic conductivity tests were performed on the wells on 16, 19 and 20 September 1988.

SECTION 6.0

FINDINGS OF INVESTIGATION

6.1 GEOLOGY/HYDROGEOLOGY

The soil boring for RB1-MW1 was drilled to a depth of twenty feet. The geologic profile logged during drilling consisted of 14.5 feet of brown, silty, clay with some sand and gravel, underlain by gray-to-brown sand and gravel to the end of boring. Headspace PID responses of 100 to 1,200 ppm were measured in soil samples collected below six feet, while hydrocarbon odors were noted over the same interval. RB1-MW1 was completed at a depth of 19 feet below grade with a ten foot screened interval from 9-19 feet. The screened interval was determined based on the wet sand and gravel deposits logged at 14.5 feet.

The borings for RB1-MW2 and RB1-MW3 encountered similar geologic profiles as logged in RB1-MW1. However, the soils did not have elevated PID readings or notable hydrocarbon odors. RB1-MW2 was completed at a depth of 15 feet below grade, while RB1-MW3 was set at 18 feet. Both wells utilized ten feet of screen. The drilling logs and well construction diagrams are included in Appendix C.

Water levels in the three wells between 16 September 1988 and 19 April 1989 ranged from seven to ten feet below land surface (732-735' MSL elevation). The aquifer is semi-confined as indicated by the water levels rising above the wet sand and gravel encountered at 14-15 feet. Ground water flow beneath the site is to the east towards Walnut Creek. Figures 6.1a, 6.1b and 6.1c are maps showing the groundwater elevations and flow direction on various dates. The water level data and well elevations are included in Appendix D.

In-situ testing of the aquifer from each of the wells indicated that the aquifer hydraulic conductivity (K) values vary significantly across the site. K values ranged from 0.009 feet/day (2.6×10^{-7} cm/sec) RB1-MW3 to 2.0 feet/day (5.76×10^{-5} cm/sec) in RB1-MW1 to 9.7 feet/day (2.9×10^{-4} cm/sec) in RB1-MW2. The aquifer test calculations are exhibited in Appendix E.

6.2 SOIL-GAS SURVEY

The soil-gas survey identified two areas of elevated BTX (benzene, toluene and o-xylene) concentration. The sample from SG-1 (Figure 6.2) contained the highest concentration (29.8 ppm), all of which was o-xylene. The only other point with detectable BTX was SB-6 where the chromatogram resembled a typical response to gasoline contamination. The remaining sampling points indicate that the concentration of volatile organic contamination in the soil profile beneath the site is very low. The soil-gas survey data are included in Appendix F.

6.3 ANALYTICAL RESULTS

The complete analytical results for soil and water samples are included in Appendix H. A discussion on the laboratory quality assurance and quality control results is presented in Appendix I.

6.3.1 Soil Results

Soil samples were collected from surface soils, hand borings, and during the drilling of the monitoring wells. Surface soil samples were analyzed for pesticides, PCBs, herbicides, semi-volatile organics and priority pollutant metals. Soil samples collected from the hand borings and during the drilling of the monitoring wells were analyzed for pesticides, PCBs, volatile and semi-volatile organics, and priority pollutant metals. The soil analytical results are summarized in Table 6.1. Figures 6.3a, 6.3b and 6.3c are maps illustrating the soil contaminants detected at various depths.

Several of the surface soil samples collected contained high concentrations of semi-volatile organics (coal tar components and phthalates). Some of these concentrations are flagged (J) due to high spiked sample recoveries. The values should be considered biased high although this should not affect the overall conclusions. See Appendix H for further discussion. In addition, several of the samples contained lead and zinc concentrations that exceeded the typical values found in Ohio soils. Table 6.2 is a summary of the standards for metal concentrations in soil and groundwater. No concentrations of volatile organics, pesticides, PCBs or herbicides were detected in the surface samples.

The cadmium levels in the surface soil samples were also elevated, however, the QA/QC results were not within control limits. The accuracy of the results is therefore questionable. Additional samples should be collected to verify the cadmium levels.

- 5) No Data Available

Soil samples collected from hand boring HB1 contained high concentrations (up to 2,150 mg/kg) of volatile organic contaminants (methylene chloride, ethylbenzene and o-xylenes). The presence of ethylbenzene and xylenes would indicate petroleum hydrocarbon contamination. Semi-volatile organics, such as coal tar components and phthalates, were detected in HB1, HB2 and HB3. Again, some of these concentrations are flagged as estimated (J). See Appendix H for a complete discussion. Metal concentrations in the hand boring samples did not exceed typical values, and no pesticides or PCBs were detected.

The soil samples collected during the drilling of MW1 contained high levels (up to 32.9 mg/kg) of volatile petroleum hydrocarbons (benzene, ethylbenzene and xylenes). Coal tar components and phthalates were also detected in soil from MW1, as well as MW2. The soil samples from MW3 contained no detectable semi-volatile organic compounds and were not analyzed for VOCs due to exceeding the sample holding time. Metal concentrations in the well boring samples did not exceed typical values, and no pesticides or PCBs were detected.

6.3.2 Groundwater Results

The groundwater samples collected from the hazardous waste storage area were analyzed for pesticides, PCBs, volatile and semi-volatile organic compounds, and priority pollutant metals. Table 6.3 is a summary of the groundwater analytical results and the Federal Drinking Water Standards for the compounds detected.

The groundwater collected from MW1 contained concentrations of benzene (94 $\mu\text{g/l}$) and xylenes (20 $\mu\text{g/l}$). The concentration of benzene exceeded the Federal maximum contaminant level (MCL) (5 $\mu\text{g/l}$) by a factor of 18.8. The groundwater from MW3 contained 44 $\mu\text{g/l}$ of trichloroethylene (TCE), which exceeds the MCL for TCE (5 $\mu\text{g/l}$) by a factor of 8.8. The only semi-volatile organic compounds detected in the groundwater were Bis(2-ethylhexyl) phthalate (24 $\mu\text{g/l}$) in MW3, and 2-Methylnaphthalene (13 $\mu\text{g/l}$) in the duplicate sample from MW1. There are no MCLs for the semi-volatile compounds. No pesticides or PCBs were detected in the groundwater samples from the three monitoring wells.

The total metal concentrations in the groundwater samples from each well exceed the drinking water standards for arsenic, cadmium, chromium and lead. However, it is unknown whether these metals were dissolved in the groundwater or present on

suspended sediment. Figure 6.4 is a map illustrating the concentration of contaminants measured in the groundwater from the three wells at the HWSA.

In addition to the dissolved contaminants in the groundwater, an immiscible hydrocarbon sheen has been observed in the water from MW1 during the monthly monitoring of the well.

SECTION 7.0

CONCLUSIONS

The conclusions from the field investigation are the following:

- Semi-volatile organic compounds (up to 37.9 mg/kg) and abnormally high metal concentrations were detected in the shallow soils at the site.
- Petroleum hydrocarbons in the form of benzene, ethylbenzene and xylenes, are present in the soil (MW1: 32.9 mg/kg) and groundwater (MW1: 116 $\mu\text{g/l}$) beneath the site. The concentration of benzene (94 $\mu\text{g/l}$) measured in the groundwater from MW1 exceeded the Federal MCL by a factor of 18.8. The areal extent of the contamination has not been defined.
- Trichloroethylene (TCE) was detected in the groundwater collected from MW3 (44 $\mu\text{g/l}$). This TCE concentration exceeds the Federal MCL by a factor of 8.8.
- The total metal concentrations in the groundwater from each of the three monitoring wells exceeded the drinking water standards for arsenic, cadmium, chromium and lead. It is not known whether the metal concentrations were dissolved in the groundwater or present on suspended sediments.

SECTION 8.0
RECOMMENDATIONS

Additional investigation is needed at the HWSA to further define the vertical and horizontal extent of the contaminants in the soil and groundwater. All environmental samples collected should be analyzed for volatile and base-neutral semi-volatile organic compounds, and priority pollutant metals. Groundwater samples should be tested for both total and dissolved metals.

Shallow soil sampling should be performed on a grid system both inside and outside the fenced area to determine the extent of surface soil contamination. Additional soil samples should be collected from soil borings to determine the vertical extent of the soil contamination. Monitoring wells should be installed in several locations to define the extent of the groundwater contaminants.

APPENDIX B

**DECONTAMINATION PROCEDURES, SAMPLE NUMBERING METHOD,
SAMPLE PACKAGING, SHIPPING AND HANDLING TECHNIQUES**

APPENDIX B

DECONTAMINATION PROCEDURES, SAMPLE NUMBERING METHOD, SAMPLE PACKAGING, SHIPPING AND HANDLING TECHNIQUES

Decontamination Procedures

All split-spoon samplers, sampling trowels, hand augers, bailers, pumps and other sampling equipment were decontaminated between samples by washing with soap and tap water, rinsing with tap water, rinsing with distilled water, and finally rinsing with isopropyl or methyl alcohol.

Augers and drill pipes were cleaned between borings by steam cleaning with tap water, washing with soap and tap water, rinsing with tap water, rinsing with distilled water and finally rinsing with isopropanol. The drill rig was steam cleaned between borings.

Decontamination wastes (water and soil) generated in the drill rig decontamination area were contained in a decontamination pad and placed in drums for later sampling and disposal. The wastes from decontamination during drilling at the HWSA were placed into drums. The decontamination water from cleaning hand augers and sampling spoons was dumped into a sanitary sewer or spread on the ground surface at the site.

Sample Numbering System

Each sample submitted for laboratory analysis was assigned a unique sample identification number that describes where the sample was collected and what type of sample it is. Each sample number consists of a group of letters and numbers separated by hyphens. A summary of the system is presented in Table B-1. For example, the first water sample collected from monitoring well 3 at Site 1 was labeled RB1-MW3-GW1. The second ground-water sample collected from monitoring well 3 at Site 1 was then labeled RB1-MW3-GW2.

Numbering of duplicate, rinseate, field blank and trip blank samples incorporated some aspects of the basic numbering system. Duplicate soil samples were assigned numbers identifying the actual site number, but utilizing fictitious sample source and sample numbers.

TABLE B-1
SAMPLE NUMBERING SYSTEM
RICKENBACKER ANGB, COLUMBUS, OH

Project Identification: RB

Site Identification and Number: Site Number: 1

Sample Source Number (sequential):

MW _____	Monitor Well #
HB _____	Shallow Soil Boring #
AB _____	Auger Boring #

Sample Number:

GW _____	Ground Water
SS _____	Soil Sample (Split-Spoon or HB)
GS _____	Surface Soil Grab Sample

Example:

RB-01-MW1-SS1

First soil sample from Monitoring Well #1 drilled at the HWSA.

Sample Handling, Packaging and Shipping

All water, sediment and soil samples collected for chemical analysis were obtained with equipment that was decontaminated prior to each use. The samples were placed in pre-cleaned glass and plastic jars and bottles supplied by I-Chem Research, Inc., via VWR Scientific. Prior to sampling, each of the sample containers was labeled with waterproof ink. Information on the labels included:

- Sample identification number;
- Preservatives added;
- Date and time of sample collection; and
- Required analytical method.

Sample containers were wrapped in packing material to minimize the chance of breakage during shipment and packed in plastic coolers. The coolers were then packed with sealed, ice-filled plastic bags. A chain-of-custody form was prepared for the contents of each cooler prior to packing. Information on each chain-of-custody form included sampling information recorded on the label of each sample bottle, the total number of sample bottles for each sample and the headspace PID screening results for soil samples. The form was then signed by the sampler(s), signed and dated by one of the samplers in the "relinquished by" box and the Federal Express airbill number was written in the "received by" box. The form was then placed in a sealed plastic bag and taped to the inside of the cooler lid. Each cooler was sealed with tape and a security seal and shipped by Federal Express to the ES Laboratories in Berkeley, California.

Upon receipt of a sample set, the laboratory inspected the shipping container for security seals before opening. The container was inspected for the chain-of-custody documents and other information or instructions. The sample custodian verified that the information on the sample bottles matched that on the chain-of-custody forms and signed for receipt. Any discrepancy between the samples received and the chain-of-custody information, broken or leaking sample bottles, or other abnormalities were reported to the laboratory supervisor. Notation of the problem and resolution was made on the chain-of-custody form, initialed and dated by the sample custodian.

Each sample was assigned a unique chronological laboratory number. A sample number label was attached to each bottle. All identifying information was recorded in a bound sample log book. The information documented included:

- Laboratory sample number;
- Date of receipt;
- Client name;
- Client identifying number or description;
- Project number;
- Analyses required, and
- Storage location.

Upon completion of the log-in procedure, the samples were stored in a secure area under the environmental conditions required to maintain sample integrity. A work order form was prepared and provided to the laboratory to assist in scheduling and completion of the tests within required holding times.

APPENDIX C
DRILLING LOGS AND WELL CONSTRUCTION DIAGRAMS

Unified Soil Classification System

Soil Classification Abbreviations

GW	Well graded gravels, gravel-sand mixtures, little or no fine
GP	Poorly graded gravels, gravel - sand mixtures, little or no fine
GM	Silty gravels, gravel - sand - silt mixtures
GC	Clayey gravels, gravel - sand - clay mixtures
SW	Well graded sands, gravelly sands, little or no fines
SP	Poorly graded sands, gravelly sands, little or no fines
SM	Silty sands, sand - silt mixtures
SC	Clayey sands, sand - clay mixtures
ML	Inorganic silts and very fine sands or clayey silts with slight plasticity
CL	Inorganic clays of low to medium plasticity
OL	Organic silts and organic silty clays of low plasticity
MH	Inorganic silts, micaceous or diatomaceous fine sand or silty soils
CH	Inorganic clays of high plasticity, fat clays
OH	Organic clays of medium to high plasticity, organic silts
PT	Peat, humus, swamp soils with high organic contents

APPENDIX F
SOIL-GAS SURVEY DATA

APPENDIX F

SOIL-GAS SURVEY DATA

The following table summarizes the soil-gas survey results for the HWSA. The table presents the benzene, toluene and o-xylene and the total BTX concentration of each sample. The soil-gas survey map (Figure 6.2) was made based on Total BTX.

The sample number identifier used in the table identifies the soil-gas point and the depth of sample collection. For example, Sample #1SG9-5 is from soil-gas point 9 collected at a depth of five feet.

Although the chromatograph was not routinely calibrated for solvents, when likely solvent peaks were noted on the chromatogram, a footnote appears on the table. Copies of the chromatograms are not included in this appendix, but will be retained indefinitely.

Footnotes

b--detection limits 8080 list (see footnote list Table G-3)
c--detection limits 8080 list (see footnote list Table G-3)
d--detection limits 8080 list (see footnote list Table G-3)
e--detection limits 8240 list (see footnote list Table G-3)
f--detection limits 8240 list (see footnote list Table G-3)
g--detection limits 8240 list (see footnote list Table G-3)
j--detection limits 8080 list (see footnote list Table G-3)

u--multiple of 2 times the detection limit given

A--analyte found in associated method blank but the sample concentration was greater than 10 times the blank concentration, therefore possibly significant

B--reported value is less than the reporting limit but greater than the MDL

DNV--data not usable

G=N*

J--value estimated due to high MS/MSD recoveries. Results are biased high.

N--spiked sample recovery not within control limits

ND--not detected

S--reported value was determined by the method of standard additions

U--analyte is less than 10 times the concentration in the blank, therefore it should be regarded as not detected

Y--post digestion spike for Furnace AA analysis out of control limits (85-115%), while sample absorbance is less than 50% of spike absorbance

*--duplicate analysis not within control limits

-- not tested

Footnotes

k--detection limits 8080 list (see footnote list Table G-3)

B--reported value is less than reporting limit but greater than the MDL

N--spiked sample recovery not within control limits

ND--not detected

S--reported value was determined by the method of standard additions

T--multiple of 10 times the detection limit given

U--analyte is less than 10 times the concentration in the blank, therefore it should be regarded as not detected

V=U/T; where U--post digestion spike for Furnace AA analysis out of control limits (85-115%), while sample absorbance is less than 50% of spike absorbance

-- not tested

APPENDIX H
LABORATORY QUALITY ASSURANCE REPORT

908DPC12-96

APPENDIX H

LABORATORY QUALITY ASSURANCE REPORT

This appendix presents a summary and review of quality assurance and quality control results for the laboratory analysis of water, soil and sediment samples collected from the Hazardous Waste Storage Area at Rickenbacker Air National Guard Base (RANGB) in Columbus, Ohio. This investigation was part of the Site Inspection during the period of June to August, 1988.

The analytical results of the environmental, duplicate and blank samples were evaluated to assess the completeness, representativeness, precision and accuracy of the data.

The completeness of the results was determined by the number of requested analyses completed within the appropriate holding times. This information is described in Table H-1 for soil samples and Table H-2 for ground water samples.

Representativeness was evaluated from the analytical results of the trip blanks, field blanks, rinseate blanks, method blanks and field duplicate samples. Analytical results of the blanks, except for the method blanks, are summarized in Table H-3. Comparison of the analytical results from duplicate samples are summarized in Table H-4 for soils and Table H-5 for water. The method blank summaries are included for each method after the tables.

Precision and accuracy were evaluated by reviewing the laboratory matrix spike sample (MS), matrix spike duplicate sample (MSD) and the surrogate spike sample. This information is shown in the Quality Control Results Summary sheets after the tables. Also included are the Case Narratives which discuss specific QC problems.

Tables H-6 and H-7 list all the soil and water samples collected at the Hazardous Waste Storage Area with their laboratory identification number for utilizing the laboratory Quality Control Results Summary sheets.

H.1 COMPLETENESS

The completeness of the data is the percentage of analyses which are judged to be valid and is determined by calculating the number of invalid analyses. The total number of invalid analyses included those analyses which were not performed by the lab and those analyses which were completed after the holding time had expired or were considered invalid for some other reasons.

Tables H-1 and H-2 summarize this information for soils and water samples, respectively. The sample ID's, date of sampling, date of extraction (if applicable) and date of analyses are indicated. The number of days elapsed from sampling to analysis and if appropriate to extraction, are shown for each analytical procedure. Analyses which exceed the holding times are marked with a dollar sign (\$). Analyses which were requested and not performed are indicated with a pound sign (#).

The total number of analyses requested was 228. Two analyses were requested and not performed and three were performed out of holding time. No analyses were considered invalid for other reasons. These 5 incomplete analyses represent only two percent of the total number of analyses requested. It is felt that 98 percent completeness is acceptable.

H.2 REPRESENTATIVENESS

Representativeness expresses the degree to which sample data represents the characteristics of a population. Therefore, the level of representativeness of the data is often determined by the methodology of the field sampling program. The methods used for the sampling of the soil and groundwater at the HWSA are described in Section 5 of the text. The sampling protocol was followed to insure a high level of sample representativeness.

Field Blanks

A field blank is a sample of the deionized organic-free water used for decontamination. It is placed directly from the source bottle into an appropriate sample container. One field blank was associated with the sampling at the

Hazardous Waste Storage Area. No volatile organics were found in this sample. The field blank data is presented in Table H-3.

Trip Blanks

A trip blank consisted of deionized organic-free water in 40 ml vials filled by the laboratory for purposes of traveling with a cooler of samples back to the lab. The trip blanks were only analyzed for volatile organics. Three out of the four trip blanks showed no detectable volatile organics. The trip blank from 10 August 1988 showed detectable levels of methylene chloride and acetone, both common lab contaminants. Both of these compounds were detected at comparable levels in the associated method blanks. Therefore, the contaminants were not introduced during the shipping process. The trip blank data is presented in Table H-3.

Rinseate Blanks

Rinseate blanks consisted of deionized organic-free water poured through the decontaminated bailer or split-spoon into sample bottles. The only volatile organics found in the three rinseate blanks were methylene chloride and chloroform, both common laboratory contaminants. These were found at low concentrations and one of them was also detected in the method blank. Therefore, their presence is most likely not caused by incomplete equipment decontamination. No other compounds (pesticides/PCBs, semi-volatile organics or metals) were found in the rinseate blanks. The rinseate blank data is presented in Table H-3.

Method Blanks

Method blanks are aliquots of analyte-free water analyzed with a sample batch to identify contaminants introduced by the preparation or analysis procedure. Method Blank Summary sheets are included after the tables. If a compound found in an environmental sample is also found in the corresponding method blank, then the result is flagged or footnoted in the results table (Appendix G). For common lab contaminants, a footnote "U" indicates the analyte is less than ten times the concentration in the blank and therefore should be regarded as not detected. For

compounds which are not common lab contaminants, the factor used is five. A footnote "A" indicates that the analyte concentration is greater than allowed by the factor and may be actually present in the environmental sample. The method blank information sent by the lab is presented after the text of Appendix H.

Duplicate Samples

Tables H-4 and H-5 summarize the analytical results of the soil and water duplicate samples. The tables only list those compounds that were detected at the site. The relative percent difference (RPD) is calculated for each compound that was detected in a given duplicate set.

For soil samples, compounds detected in the sample are usually also detected in the duplicate sample. For some of the samples, the RPD was somewhat large for the volatile and semi-volatile organics. However, this usually happens when the analyte is present at a concentration less than five times the detection limit or the analyte found is a common laboratory contaminant. The metal results for the soil duplicate samples generally correspond well. The metals that were detected in the sample were usually also detected in the duplicate. Given the heterogeneous nature of soil and the volatility of the organic compounds, the data for soil samples should be considered representative.

One water sample was duplicated from the Hazardous Waste Storage Area. Two organic (acetone and benzene) compounds were found and neither could be confirmed by the duplicate sample because the volatiles were analyzed out of holding time and therefore considered estimated. Acetone was also found in the method blank so its presence is not significant.

The duplicate water results for the total metals were in agreement. The same metals were present in both samples at comparable concentrations. The analytical results for the ground water samples should be considered representative except for the benzene example noted above.

H.3 PRECISION AND ACCURACY

Precision and accuracy are assessed from the results obtained from the analysis of matrix spike and matrix spike duplicate samples.

Precision

Precision refers to the relative percent difference (RPD) in values obtained from two duplicate samples, in this case matrix spike duplicate samples. RPD is calculated as follows:

$$\text{Relative Percentage Difference (RPD)} = \frac{2 (C_1 - C_2) \times 100}{C_1 + C_2}$$

where:

C1, C2 = The two values obtained by analyzing duplicate samples.

Acceptable levels of precision vary according to the sample matrix, the specific analytical method, and the analytical concentration relative to the method detection limit.

The precision obtained for metals analyses was evaluated based upon a control limit of 20 RPD for values greater than 5 times the detection limit. A control limit of 2 times the detection limit was used for values less than 5 times the detection limit. If either value was less than the detection limit, an RPD was not calculated.

The precision of the analyses of volatile halogenated compounds and volatile aromatic compounds was evaluated on the basis of the RPD calculated for quantitation on a single chromatograph column. The EPA methods for these analyses provide statistical precision data as a function of concentration for individual compounds. These values are used as a guideline to assess the precision of duplicate analyses.

Accuracy

Accuracy refers to the correctness of the value obtained from analysis of a sample, and is determined by analyzing a given sample and its corresponding matrix spike sample. Accuracy is expressed as percentage recovery (PR) and is calculated using the following formula.

$$\text{Percentage Recovery (PR)} = \frac{S_s - S_o}{S} \times 100$$

value:

S_o = Background value, the value obtained by analyzing the sample before spiking;

S = Concentration corresponding to the spike addition to the sample; and

S_s = Value obtained by analyzing the matrix spike sample with the spike added.

The degree of accuracy, or percentage recovery (PR), to be expected is dependent upon the sample matrix, specific analytical method, and the concentration of the analyte relative to its detection limit. The closer the measured value is to the detection limit, the lower the accuracy of analysis. Metals and other inorganic water quality parameters are normally determined within the range of 70 to 125 percent or as specified by ES Laboratory Control Charts.

The procedures for spike samples to be analyzed by gas chromatography Methods 8010, 8020, 8240, 8270 and 8150 are described in each respective method. The expected range for recoveries of each compound are also provided in the method descriptions.

The Laboratory Quality Control Results Summary sheets for each analytical test performed are included after the tables.

If quality control results demonstrated an out of control situation for the spiked sample or spiked duplicate sample, a corrective action was taken. This may have included checking the calculations, flagging data in accordance with the procedures

prescribed for the method, recalibration of the instrument, and/or re-analyses of the samples.

Semi-volatile organic analysis of spiked samples resulted in some high recoveries. Since the spiked blank samples were within an acceptable range, data associated with these batches were still considered usable, but flagged as estimated (J). Since the recoveries are generally high, the flagged analytical results should be considered biased high. If spiked blank recoveries were out of range but the spiked sample recoveries were within range, no further action was taken (eg., 1,2,4-trichlorobenzene for QC Report No. BNA-S-0032-88B).

QC Report No. BNA-S-0032-88B shows very poor, spiked blank recoveries. The Case Narrative associated with this report concludes that the lab does not feel the quality of the data are affected. Since the only sample associated with this report (RB-1-MW2-SW1) does not show any detected semi-volatile organics, no further action is necessary.

Analytical results of environmental samples marked with the following footnotes should be regarded as approximate:

- N - Spike sample recovery not within control limits.
- * - Duplicate analysis not within control limits.
- W - Post digestion spike for Furnace AA analysis out of control limits (85-115 percent).

The abundance of the footnote "N" in the metal analytical results indicates that there may be a laboratory control problem for some of the metals.

CASE NARRATIVES
QUALITY CONTROL SUMMARIES
METHOD BLANK SUMMARIES
CHAIN-OF-CUSTODY

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
QC REPORT NO.: BNA-W-0026-88

Since insufficient sample was available for QC purposes, a blank was designated as the QC sample for this batch. A sufficient portion of the first base neutral extract of the MSD was spilled. Rather than restart the extraction, the technician continued with the procedure. This should not happen in the future. This caused low recoveries in the spike duplicate and high RPD's in the spiked sample set. Subsequent spiked blank sets (see QC Report BNA-W-0025-88) gave results that met EPA QC guidelines, with the exception of slightly low recoveries for acenaphthene. This should not affect the quality of the sample data.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Samples No.: 88061106-88061124
QC REPORT NO.: BNA-S-0018-88

The sample selected to be the matrix spike and matrix spike duplicate for method SW8270 contained large amounts of hydrocarbon. Even after dilution, the sample contained interferences that made spike data inaccurate. A spiked blank and duplicate were analyzed for this set of samples. The percent recoveries of all spiked compounds were within EPA recommended guidelines but three of the base neutral relative percent differences were above EPA recommended limits.

Samples 88061114-88061116 were analyzed as high level samples because of high concentrations of hydrocarbons. High level extracts of sample 88061117 were used as QC for these samples. The values reported for 88061117 are from a low level analysis of this sample.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
QC REPORT NO.: BNA-S-0032-88
QC REPORT NO.: BNA-S-0032-88B

Analysis of matrix spike samples for this batch resulted in recoveries of several compounds that were higher than EPA QC limits, and a high RPD for pentachlorophenol. Analysis of spiked blanks resulted in a slightly low recovery for 1,2,4-trichlorobenzene and high RPD's for both dichloro and trichlorobenzene. The analytical data for these analyses was closely examined and no problems were discovered.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Samples No.: 88061106-88061120
Samples No.: 88071315-88071333
WORK ORDER NO.: 696

The nature of the sample used for matrix spikes required it to be diluted for analysis. This brought the spiking levels of the matrix spiking compounds below the practical quantitation limit, making quantitation uncertain. Analysis of laboratory control samples showed the laboratory to be in control.

Endrin recovery from one of the spiked blanks is higher than ES Laboratory control limits.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Samples No.: 88061106-88061120
Samples No.: 88071315-88071333
WORK ORDER NO.: 730

The nature of the sample used for matrix spikes required it to be diluted for analysis. This brought the spiking levels of the matrix spiking compounds below the practical quantitation limit, making quantitation uncertain. Analysis of laboratory control samples showed the laboratory to be in control.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
SAMPLE NO(S).: 88081769-88081770
WORK ORDER NO.: 824

The samples listed above did not receive an analytical spike for the analyte thallium. This was due to an oversight by the analyst who prepared the samples. There was insufficient sample to repeat the digestion with the proper spike added.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
SAMPLE NO(S).: 88092533-88092538
WORK ORDER NO.: 1011

The samples listed above did not receive an analytical spike for the analyte thallium. This was due to an oversight by the analyst who prepared the samples. There was insufficient sample to repeat the digestion with the proper spike added.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
SAMPLE NO(S).: 88092642-88092643, 88092646
WORK ORDER NO.: 1032

The samples listed above did not receive an analytical spike for the analyte thallium. This was due to an oversight by the analyst who prepared the samples. There was insufficient sample to repeat the digestion with the proper spike added.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
QC REPORT NO.: AAF-W-0040-88

The Relative Percent Difference for arsenic is not calculated since the sample values are less than five times the reporting limit. Acceptable RPD in this case is defined as duplicate values within one detection limit of each other.

Lead QC for furnace is applicable only to sample no(s). 88092534, 88092556, 88092558, 88092686, 88092692, 88092641-88092644, 88092650-88092651 and 88092646.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Samples No.: 88061115, 88061117, 88061119
QC REPORT NO.: ICP-S-0017-88

Spike recovery outside acceptable limits for this batch of samples prepared on August 5, 1988 is attributed to the spiking solution and procedure used and not to sample matrix interference. Analytical (post-digest) spikes performed at the time of the analysis resulted in acceptable levels of recovery, unless noted below:

Beryllium - Analytical spike recovery - 60%

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Samples No.: 88071458-88071461, 88071477-88071478
QC REPORT NO.: ICP-S-0019-88

Spike recovery for this batch of samples prepared on July 25, 1988 is attributed to the spiking solution and procedure used and not to sample matrix interference. Analytical (post-digest) spikes performed at the time of the analysis resulted in acceptable levels of recovery, unless noted below:

Silver - Analytical spike recovery - 64%

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
QC REPORT NO.: ICP-S-0041-88

The Relative Percent Difference for chromium is not calculated since the sample values are less than five times the reporting limit. Acceptable RPD in this case is defined as duplicate values within one detection limit of each other.

Lead QC by ICP is applicable only to sample no(s). 88081769, 88081770, 88081775-88081778, 88081780, 88081783, 88081891, 88081893-88081894 and 88081918-88081919.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Samples No.: 88071460-88071461, 88071477-88071478
QC REPORT NO.: OCP-S-0018-88

Endrin aldehyde and Kepone were not recoverable because they were removed by the alumina column clean-up used on these samples.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Samples No.: 88081762-88081765
Samples No.: 88081769-88081770
QC REPORT NO.: OCP-S-0026-88

Gamma-BHC in the matrix spike duplicate sample for this batch was masked by an unknown interference. Thus, the percent recovery and relative percent difference could not be calculated for this compound in this QC set. Spiked blanks were analyzed and the results were within EPA guidelines.

Heptachlor epoxide was inadvertently used instead of heptachlor in the matrix spiking solution.

Endrin aldehyde and Kepone were not recoverable because they were removed by the alumina column clean-up required by these samples.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
EPA METHOD 8240
WORK ORDER NO.: 1011

The 8240 analysis of samples 88092538 and 88092539 were performed less than two hours after the expiration of holding time. The first analysis of sample 88092536 showed a quantity of benzene, xylene and ethyl benzene that was above the calibrated range. It was not analyzed again until about one month later, when another vial with the same label was analyzed. This analysis (performed three times) showed only a small amount of benzene and no detectable amounts of xylenes or ethylbenzene. Examination of the chromatograms and spectra indicate a hydrocarbon envelope. If there had been a lens on the surface of the first bottle, that would explain this phenomenon. Results of the second analyses are presented in this report.

CASE NARRATIVE
QUALITY CONTROL RESULTS SUMMARY
Sample No.: 88071571
QC REPORT NO.: OCP-W-0019-88

Insufficient sample was available for quality control purposes. The laboratory control sample is designated as a quality control sample for this batch.

Endrin aldehyde and Kepone were not recoverable because they were removed by the alumina column clean-up used on these samples.

Heptachlor epoxide was accidentally substituted for Heptachlor in the matrix spiking solution.
