I. INTRODUCTION

A. Section II provides a summary of adult, larval, and oval mosquito specimens we received and identified from Air Force installations in the Pacific during CY 87. A total of 46,654 specimens were identified during the year, including 24,068 adults, 5,990 larvae, and 16,596 eggs (based on reared adults). Material from 16 PACAF and 1 SAC installations was received. Appendix A contains information prepared by Lt Col Dennis D. Pinkovsky on mosquito surveillance, data interpretation, and control.

B. BASE SUMMARIES

A synopsis of the annual data for all the facilities is provided at the beginning of this section. Statistics are then provided on the number of specimens and species submitted to OL AD, USAFOLH/VTIS by each participating base. Monthly trap indices are presented along with total trap collection figures.

NO. OF OVITRAP PADDLES AND EGG COUNT - 1987
(BASED ON DATE COLLECTED)

MONTH	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	TOTAL
PADDLE COUNT	13(3)*	5(3)	2(0)	6(2)	2(0)	14(0)	19(0)	17(7)	17(15)	5(4)	0	0	100(34)
EGG COUNT	160	46	0	9	0	0	0	95	1170	122			1602

*The number in each parentheses is the number of paddles positive for Aedes spp. eggs.

Rearings of positive ovitrap paddles produced all Aedes albopictus (159 females, 215 males).

I. MOSQUITO SURVEILLANCE*

A. Environmental Survey. To establish or strengthen a mosquito surveillance program, an annual baseline environmental survey should be accomplished at every Pacific area Air Force installation at the beginning of each mosquito season. Such a survey could, for example, be made during April-May in Okinawa, May-June in Korea and Japan, and in the Philippines and Guam with a year-long mosquito season, during the early rainy season (May-July). The survey involves the first noting or plotting on a topographical map the prevailing winds and the base swamps, lakes, and other permanent and stationary water bodies, streams and other flowing water, major open drainage ditches, other mosquito breeding sites such as low, water-collecting areas near flight lines, and wooded or other areas known from past experience to be regions of intense adult mosquito activity. A thorough search by vehicle and on foot is then made to confirm that previously known breeding areas still hold water and to locate new, potential mosquito breeding spots which are then indicated on the map. Consideration should be given to pest/vector production from man-made breeding sources like clogged rain gutters and storm sewer catch basins and mosquito infiltration from suspected or known mosquito breeding sources nearby off base. Possible on-base breeding sites identified in the environmental survey are sampled during routine larval surveillance throughout the mosquito season and control efforts are directed at locations positive for mosquito immatures to minimize on-base generation of adult mosquitoes.

B. Adult Mosquito Collections

1. New Jersey Trap. The New Jersey (NJ) trap (NSN 3740-00-607-0337) is the primary tool used for adult mosquito surveillance on Pacific theater Air Force installations. This sturdy metal trap is normally placed in permanent or fixed locations during a given mosquito season. For computer entry of trapping data, the collecting sites should be coded T-1, T-2, and so on, and OL AD/ES should be provided a short letter at the beginning of each mosquito season which lists the site codes and gives a brief description of each location. PACAF Supplement 1 to AFR 161-1 outlines the required minimum number of NJ mosquito traps and trapping nights per week based on installation population. Generally, this is three to five traps operated three evenings each week. Traps are placed in fairly secure spots where the possibility of pilferage is low and where disturbances due to other lights and wind will be minimal but trap light visibility is not too restricted and electric power is available for non-battery operated traps. Traps may be placed near the base perimeter to detect mosquitoes invading from off-base

*Information in this appendix was prepared by Lt Col Dennis D. Pinkovsky for the CY 85 mosquito summary. The data included should be particularly beneficial for individuals who have not worked in mosquito surveillance programs before.

breeding sources, in critical populated areas of the base (housing areas, flight line maintenance areas--an MQI program requirement, golf course, main base) or between the populated areas and known mosquito production locations. Locations just within the margins of woods or swamps are often very productive mosquito collecting spots. Trap locations are marked on the map. In general, mosquitoes have relatively short flight ranges, and the farther traps are located from known mosquito breeding areas, the fewer mosquitoes one would normally expect to catch. Traps are suspended so that the light bulb is five to six feet above the ground, and traps can be secured with cables to retard possible swinging. Civil Engineering can construct simple, inverted L-shaped, concrete-based, trap supports. Some installations incorporate electrical outlets into the trap support design; other bases hang traps from tree limbs and supply electrical power by extension cords. Avoid hanging NJ traps from fencing which may accidentally become electrified. A 60-watt white incandescent light bulb serves as the "attractant" for the trap; alternatively, carbon dioxide as dry ice can be used to draw mosquitoes into the trap vicinity. Figure 1 shows a schematic NJ trap equipped with light and carbon dioxide. The dry ice is placed in a styrofoam container located above the trap, and the CO₂ flows through a tygon tube and exits underneath the trap rain cover. Insects lured by the light or CO₂ are pulled downward by the trap fan along a screen funnel into the collecting or kill jar. An exclusion screen of 1/4 inch mesh hardware cloth prevents large beetles and moths from reaching the collection of fragile mosquitoes. Vapors from a 1- to 2-inch section of DDVP-impregnated resin fly strip (No-Pest^R) placed in the bottom of the jar kills captured insects. A paper or plastic cup, perforated with many small holes, should be placed in the mouth of the kill jar to retain insects and keep the mosquitoes off the insecticide strip but allow entrance of killing vapors. Light traps are operated from sunset to sunrise; CO₂-baited traps can be operated for 24-hour periods to collect day-flying as well as night-flying mosquitoes. Carbon dioxide generally attracts greater numbers and a greater variety of mosquitoes and far fewer beetles, moths, and other unwanted insects than does light. Photoelectric attachments or electrical timers may be connected to the NJ light traps to switch them on at dusk and off at dawn. Specimens should be retrieved from the killing jar each morning after a night of trap operation. Female mosquitoes should be separated from male mosquitoes and non-mosquitoes, and the number of female mosquitoes in each trap should be logged. Prevailing temperature, phase of the moon, wind, and rain, in addition to control efforts, are some factors which can affect trap collections. EHS personnel should telephone mosquito trap counts and other surveillance information in a timely fashion to Civil Engineering (CE) Pest Control, and EHS should receive from CE a written report on mosquito control activities at the end of each month of the mosquito season. Correlated with complaint calls due to mosquitoes, historical information from past outbreaks of mosquito-borne disease, and other factors, control trigger numbers or the number of female mosquitoes per trap which indicate ground-based fogging efforts are needed can be established. Captured mosquitoes should be packaged for shipment (Section IV) and mailed for identification each week. The numbers and species of submitted adult mosquitoes are reported by VTS to each installation on AMD Form 658, Female Mosquito Identifications.

Figure 1. CO_2 -Baited NEW JERSEY Light Trap

2. Solid State Army Miniature Light Trap. A portable, light weight, battery-powered mosquito trap developed by the US Army and available in the Federal Supply System is the Solid State Army Miniature Light Trap (SSAM), NSN 3740-01-106-0091 (Figure 2). The SSAM trap replaced the earlier Centers for Disease Control (CDC) portable trap. This trap weighs about four pounds including the battery. Features include a clear plastic trap body, solid state circuitry, an improved fan and motor, improved light bulb, and a photo-electric switch. The SSAM trap is especially useful for augmenting NJ trap collections by allowing the monitoring of mosquitoes in base areas where electrical outlets are unavailable. Mosquitoes may be collected alive in a cloth mesh bag (useful for mosquito-borne viral disease studies) or dead in a kill jar. The live-caught specimens can be killed by freezing in the laboratory and, when thawed, they are usually in excellent, undamaged condition for packaging and identification. The SSAM trap automatically activates at dusk as daylight decreases; increasing light at sunrise deactivates the light bulb but the fan continues to operate to retain mosquitoes captured live in the mesh bag. A gel-cell rechargeable battery (NSN 6140-00-432-0490) and battery charger (NSN 6130-00-629-7396) are available for the trap. Like the NJ trap, the SSAM trap can use dry ice as the mosquito attractant for the trap. Precautions must be taken to minimize pilferage in the field of these compact mosquito traps. Replacement light bulbs are available under NSN 6240-00-761-0979 (10 bulbs/box). If rain is anticipated, especially when using the cloth collection bag, place the SSAM trap under a roof overhang or other shelter to minimize weather-caused specimen damage.

3. Fay-Prince Trap. A portable, light weight, battery-powered mosquito trap specifically intended as a daytime trap for the collection of male and female Aedes aegypti and Aedes albopictus mosquitoes (vectors of dengue viruses) is the Fay-Prince trap (Figure 3). The design is based on the attraction of contrasting glossy black and white panels. There is a wind-orienting trapezoidal cover, a cylinder holding a suction motor, and a suspended collection bag. There is no trap light. The trap should be placed in the vicinity of suspected mosquito breeding sites, especially in the backyards of or between human habitations. This trap should be positioned in a location somewhat protected from the wind and three feet above the ground (interference from animals and children may be a problem). If rain is a possibility, a roof overhang or other additional rain protection is advisable. Dry ice can increase the mosquito catch. The trap operates on a 6-volt power source; the Federally stock-listed gel-cell rechargeable battery mentioned in the SSAM trap discussion above is appropriate for running the Fay trap. The Fay-Prince trap (Model 712) is available for approximately \$125.00 from the John W. Hock Co., P. O. Box 12852, Gainesville, Florida 32604.

4. Resting Collections. Mosquitoes which fly and bite at night (most do this) can be collected during daylight hours while they rest in culverts, beneath bridges, in tree holes, inside sheds, or in other shaded locations. Artificial resting sites can be made from one cubic foot wooden or cardboard boxes which are painted red inside and placed in woods, swamps, near shrubbery or elsewhere; the next morning the boxes can be examined for mosquitoes sheltering in them. A flashlight and a battery-powered aspirator

Figure 2. **Sold State Army Miniature (SSAM) Trap**

Figure 3. Fay-Prince Trap

make capturing mosquitoes in resting sites relatively easy. The captured mosquitoes are transferred to holding containers and then killed by freezing and prepared for shipment and identification.

5. Landing/Biting Collections. Landing or biting collections of mosquitoes using humans as the attractant hosts in different areas of the base can give an indication of the actual intensity of human biting mosquitoes in different locations and can be compared with mosquito trap counts to better determine control trigger numbers. Mosquitoes attracted to and landing on or biting the exposed body portion such as legs of a person are collected with an aspirator and counted for periods of 5 to 15 minutes. Individuals differ in attractiveness to mosquitoes so the same individual must be used in all areas for valid comparisons. Naturally, mosquito repellents must not be applied. Landing/biting collections using personnel as the attractant hosts are not recommended in areas where transmission of mosquito-borne diseases is a possibility unless adequate chemical prophylaxis against all potential mosquito-borne diseases can be assured. Carabao, dogs, birds, or other animal hosts can be used in Magoon (baffled)-type traps or fully exposed as bait for biting collections, but such animal bait collections do not reflect true human biting activity.

C. Collections of Mosquito Immatures

1. Mosquito Larvae and Pupae Surveys. If mosquito populations can be discovered in the less mobile wriggler or larval stage, or as pupae, and killed, the blood-seeking, pathogen-transferring adult female stage is avoided. Mosquitoes develop in almost any type of water--rice-fields, ditches, swamps, salt marshes, stream edges and pools, carabao wallows, ground pools, sewer catch basins, clogged rain gutters, discarded vehicle tires, open washing machines in salvage yards, tree holes, leaf axils of Pandanus, banana, and other plants, and so on. In surveys for the immature stages of mosquitoes, at least twenty sites should be sampled semimonthly. A white-colored dipper, vials, MacGregors (see Section IV) preserving fluid or 80% ethanol, a wide orifice eye dropper, and boots are the basic larval sampling essentials. In dipping, the trick is to rapidly submerge one side of the dipper allowing water and larvae to flow in but not overflow the container. Avoid casting shadows or disturbing the water surface before each dip; disturbed larvae will submerge and can remain at the bottom of the breeding site for a few minutes. Try to collect large (late instar) larvae; they are more easily identified. Place all larvae from one sampling site in a vial separate from larvae collected at other locations. Each vial must contain a label (written in pencil) which includes the collection site (for example: L-1, grassy ditch at Bldg 32 or L-2, ricefield near TMO), installation, date, and name of collector. (Note: If live larvae are left too long in water with a penciled soft paper label, the insects' "grazing" feeding behavior may obliterate the label information.) Place larvae in vials of water in the field, "fix" the larvae in hot but not boiling water in the laboratory, and ship the larvae in appropriately labeled vials of preservative (see Section IV). Mosquito pupae are difficult to identify and pupae are not normally submitted; however, live mosquito pupae collected in the field can be placed in small containers of water or on moist paper

toweling in labeled petri dishes and held alive to allow the adults to emerge, which are then killed, packaged, and sent for identification. Notify CE Pest Control of locations positive for mosquito larvae and pupae for control action. For submitted larval specimens, VTS will return AMD Form 652, Larval Mosquito Identifications, with annotations of the mosquito species and numbers that were submitted.

2. Ovitraping. Installations in Guam, Hawaii, Okinawa, and the Philippines, in particular, should monitor populations of container-breeding Aedes mosquitoes by using oviposition traps or ovitraps. These glass or plastic, wide-mouth, pint jars are painted glossy black on the outside, an inch or two of water is placed into each jar, and a "paddle" is affixed vertically with a clip to the inside of the jar. The paddle is the rough surface on which the Aedes females lay their eggs and can be made by wrapping a GI-brown paper towel around a wooden tongue depressor and securing it with rubber bands. Aedes aegypti and Aedes albopictus, important vectors of dengue viruses, are usually not readily collected in other standard mosquito traps, and the ovitrap is an effective means for locating and monitoring populations of these mosquitoes. Ten to twenty ovitraps are positioned at ground level in shaded but visible locations (near shrubbery, under elevated homes, against or inside open sheds) for periods of one week in small sections of housing areas or other appropriate populated base areas. The ovitraps are visited each week, paddles are removed and placed into individual, labeled (site, base, date) plastic bags, and the paddles are shipped to VTS for examination and identification (through egg hatching and specimen rearing) of the species which deposited any eggs present.* Mosquito larvae and pupae present in the ovitrap water are also collected, placed in a vial of preservative, and submitted for identification. The ovitrap jars are flushed with clean water, fresh water and a new paddle are added, and the traps are left for a second, third, or fourth week at the same locations or are repositioned to a new area of the base. Checking and cleaning the ovitraps each week (every 7 days) is critical because under appropriate conditions the Aedes mosquitoes (or other container breeders) can develop from eggs to adults in as little as nine or ten days and ovitraps must not be allowed to become mosquito breeding locations. A search should be made within 100 yards or so of positive ovitraps for flower pots, clogged rain gutters, or other breeding sources of the detected Aedes populations.

D. Monthly Mosquito Surveillance Activities Summary (AMD Form 208). Shown on the next page (Figure 4) is a sample AMD Form 208, Monthly Mosquito Surveillance Activities Summary. Environmental Health Services at each Pacific area base should complete and submit to ES one AMD 208 at the end of each month during the mosquito season. Each trapping date should be indicated, whether or not mosquitoes were captured. Sections are provided for summarizing adult trapping, ovitraping, and larval surveillance

* Operational Note: Open the plastic bags and let the paddles air dry one day prior to shipping. This helps curtail hatching of moist eggs in shipment. Also use clear (ziplock) plastic bags without any commercial writing on them; this assists the examination efforts of our vector taxonomist.

MONTHLY MOSQUITO SURVEILLANCE ACTIVITIES SUMMARY

activities. This form assists your own periodic internal review of the mosquito surveillance program and helps us at OL AD identify problem areas (maintenance, aged traps, trap location problems, etc.) which we can assist you in solving.

II. DIFFERENTIATION OF COLLECTED ADULT SPECIMENS

A. Mosquitoes from Non-Mosquitoes. The females of most species of mosquitoes (order Diptera, family Culicidae) are blood suckers. The mosquitoes are characterized, among other body features, by their relatively small size (about 1 cm long), typical wing venation, presence of many scales on wings and body, and long central proboscis on the head (see Figure 5A)*. Other flies which may be captured in traps along with mosquitoes that have similar size and appearance and may be confused for mosquitoes include the dixerid, phantom, and chironomid midges. The latter is shown in Figure 5B. These non-mosquito insects lack the central proboscis, are not blood feeders, and lack or have far fewer scales on the wings.

B. Female Mosquitoes from Male Mosquitoes. Differences in the appearance of the antennae enable separation of the females from the males of most mosquito species. The antennae of male mosquitoes (Figure 5, F & H) are very bushy or plumose compared to the relatively short-haired antennae of the females (Figure 5, E & G). The males of most mosquito species have maxillary palps which extend beyond the central proboscis while the palps of the females are much shorter. In Anopheles species, however, the palps are relatively equivalent in length in both sexes but the male's palps are clubbed (swollen) at the distal end.

III. PACKING AND SHIPPING

A. General. Dead, preserved mosquito specimens submitted for identification should be prepared for shipment as described in this section. Viable mosquito eggs on ovitrap paddles are the only live specimens that should be submitted without first contacting OL AD at AV 89-33245. All mosquitoes submitted for identification must be labeled with the following: (1) locality--place of collection (Osan AB, Korea); (2) source--T-1 (NJ light trap #1); T-2 (CO₂-baited NJ trap #2), L-4 (Larval station #4), and so on; (3) collector--Sgt Sharpsky, SGPM; and (4) date--day, month, and year of collection. Ship all mosquito specimens to: Vector Taxonomy Section (VTS), OL AD, USAFOEHL, APO San Francisco 96528-0007.

B. Adult Mosquitoes

1. Pick up the insects accumulated in the killing jars of the mosquito traps each morning after a night of trap operation. Separate the female

mosquitoes from the unwanted insects and pack them for shipment as soon as possible. If the time between the end of the collection period and the time the mosquitoes are packed exceeds 6 hours, the specimens dry and become brittle. When brittle mosquitoes are packed, legs, wings, and other parts necessary for identification break off, and the mosquitoes cannot be identified. Poor collection discipline results in specimen loss due to: compression by the weight of excessive numbers of insects, mold formation, or excessive killing time because the killing agent cannot penetrate the thick layer of accumulated insects.

2. Mosquitoes packaged for shipment in the manner depicted in Figures 6A through D below will arrive in excellent condition and be identifiable. A number of the culture dishes may be required to handle a large collection of mosquitoes. Proper labeling of each container is essential. The necessary packaging materials are available to all Environmental Health Services offices and consist of facial tissues and plastic petri dishes (Dish, culture, Petri, top and bottom complete, FSN 6640-01-030-9012).

3. Stack and tape multiple culture dishes together. Pack the plastic dishes for shipment in a strong cardboard carton which is large enough to insure that the dishes are surrounded on all sides by at least 1 inch of packing material. Packing material can be styrofoam chips, wadded tissues, paper towels, rolled newspapers, or anything of this nature. The carton should be taped securely shut so that it cannot open in the mail.

C. Larval Mosquitoes

1. Ship all larvae from a single collection site in one container. Do not mix larvae from two or more collection sites in the same container of preservative. If possible, kill the larvae by placing them in hot, but not boiling water for two minutes. The water from a hot water tap is normally scalding enough for this purpose. The hot water prevents the larvae from turning black and becoming difficult to identify. Drain the water from the mosquitoes before adding the preservative. If hot water is not available, the larvae may be placed in a mixture of glacial acetic acid and alcohol (1:6) to kill them and then can be transferred to a shipping vial or bottle filled with preservative. Larvae can also be placed directly in the preservative after all field-collected water has been drained from them.

2. Larvae are generally preserved and shipped in 80 percent ethyl or isopropyl alcohol. Ethanol is superior to isopropanol. These preservatives may, however, cause hardening and distortion of the larvae which make identification difficult. Environmental Entomology Services recommends that MacGregor's solution, rather than alcohol, be used for preserving and shipping mosquito larvae. This solution is made by dissolving 5 grams of borax (sodium borate) in a small amount of water, then adding 2.5 ml of glycerine and 100 ml of 37 percent formaldehyde to the mixture, and finally adding sufficient distilled water to make a total volume of 1 liter (1000 ml).

Figure 6A

Place a piece of tissue over the bottom half of the culture dish, as diagrammed. The tissue must be large enough to completely cover the dish, with 1 inch of overlap on all sides.

Figure 6B

Using fine pointed forceps, gently place mosquitoes on the tissue covering the culture dish. Mosquitoes should be positioned so that they do not touch each other. From 16 to 30 mosquitoes will usually fit into each container, depending on the size of the specimens.

Figure 6C

Cover the mosquitoes with a second piece of facial tissue.

Figure 6D

Place the cover of the culture container on the bottom portion. Press the 2 halves together and tear off excess tissue. The halves of 5 cm (diameter) culture dishes fit snugly and need not be taped; larger petri dishes, if used, should be taped together. Write necessary collection data on the culture dish with a china marking pencil or, better, a permanent felt-tipped lab marker.

Figure 6. Packaging Adult Mosquitoes

The nomenclature and National Stock Numbers for these items are:

Sodium borate, ACS, 6810-00-234-8369, 1 lb bottle

Glycerine, USP, 6505-00-153-8220, 1 lb bottle

Formaldehyde solution, USP, 6550-00-139-1321, 1 pt bottle

3. Write the collection data specified above on a small piece of paper and insert it into the preservative along with the larvae. It is imperative that only pencil or waterproof India ink be used to write the collection data, as any other type of ink will dissolved in the preservative. Do not use a ball point pen. Allow India ink labels to dry overnight before inserting them.

4. The bottles or vials used to ship the mosquitoes should be filled with preservative as completely as possible to minimize the amount of air space and reduce the jostling of the larvae during shipment. Screw cap vials or bottles may be used but the tops should be securely tightened and taped to prevent loosening of the caps and leakage. Lip vials (4-dram is a convenient size for most collections) or blood collecting tubes sealed with rubber stoppers are also recommended. Air bubbles and excess fluid may be removed with a hypodermic needle positioned in the neck of the vial or tubes as the stopper is inserted.

5. For shipment, wrap each vial individually in several layers of paper toweling, cellucotton, or a similar material. These wrapped vials can then be packed by the same method as described for packing adult mosquitoes, and mailed to VTS for identification.

D. Ovitrap Paddles. Remove paddles from ovitrap jars and place each paddle in a small zip-lock, twist-tie, or similar plastic bag. Air dry paddles one day in the lab, then reinsert paddles into the bags, seal each bag and be sure each bag bears the appropriate collection information including, in particular, the base, ovitrap number, specific location, and the date collected. Cushion the bags with the paddles inside a cardboard carton and mail to VTS.

IV. TRAP COUNT INDICES*

A. Definition. Trap indices (TIs) are numbers calculated from mosquito trap counts which serve as indicators of trends of the size of the mosquito populations that were sampled. These numbers may be plotted on a graph for visualizing population fluctuations over time, as in Figures 7 and 8. They may represent a consolidation of all specimens collected (Figure 7) or they may be plotted for individual species (Figure 8). Individual species plots can also be drawn on the graph with the consolidated specimen line(s) to show individual species deviations compared to the overall picture.

* Modified from 6201 EPID FLT RPRT ENT 78-003.

Figure 7. Weekly mosquito trap indices for all specimens taken during successive years at Nampyeong Air Base, Korea.

Figure 8. Specific trap indices for vector species at Naplong Air Base, Korea.

B. Mechanics

1. Daily and Weekly Trap Indices. Daily and weekly trap indices (DTI and WTI) are computed as follows:

$$DTI = \frac{A}{B}$$

$$WTI = \frac{C}{D}$$

where:

A = Number of female mosquitoes collected in one night

B = Total number of traps operated that night = number of trap nights

C = Number of female mosquitoes collected in one week

D = Total trap nights that week

One trap night equals the operation of one trap for one night. The figure for total trap nights for the DTI equals the number of traps operated that one night. The total trap nights figure for the WTI, "D", is the total number of trap operations during one week. This number is obtained by multiplying the number of traps used by the number of nights they were operated. For example, 4 traps each used 3 full nights during the week equals 12 trap nights. A trap which was nonoperational one night for any reason is not figured into the denominator; however, a trap which was operated but captured no mosquitoes is figured into the denominator with 0 being computed into the total number of female mosquitoes. Note the following example where 2 traps were used for 3 nights per week:

<u>Date</u>	<u>Light Trap No.</u>	<u>No. of Female Mosquitoes</u>
21 June	1	8
	2	0* (trap operated - no mosquitoes captured)
22 June	1	17
	2	30
23 June	1	0** (trap not operational)
	2	25

$$WTI = \frac{(8 + 0* + 17 + 30 + 25)}{(2 \times 3) - 1**} = 16$$

2. Specific Trap Indices. Each installation has one or more species of mosquitoes which, due to their role as severe pests of man or importance as disease vectors, warrant close monitoring. A specific Trap Index (STI) may be calculated for one or more species as follows:

$$\text{STI} = \frac{\text{Total number of female mosquitoes collected of specific vector or pest species known to occur on the base}}{\text{Total number of trap nights on the base for the designated study or sampling period}}$$

Examples:

For Anopheles sinensis, an important vector of malaria in Korea, the STI equals the total females of Anopheles sinensis collected during one week divided by the number of trap nights in that week.

For a Japanese B encephalitis vector in the Philippines, the STI equals the total females of Culex tritaeniorhynchus captured in one week divided by the number of trap nights in that week.

Figure 8 illustrates typical plots based on the STIs for 2 species.

3. Localized Mosquito Upsurges. The above discussion deals with manipulations of the actual numbers of mosquitoes captured and the calculation of averages or arithmetic means; however, there are pitfalls in using averages. A large collection of mosquitoes in one or a few traps of a series can give a false indication of the actual insect populations on an installation as a whole. For example, hypothetically, if 10 traps are used and 1 is placed in an area where mosquitoes are continually or sporadically very numerous compared to the other trap locations, a situation as follows may occur: in 9 traps a total of 50 mosquitoes is caught and 450 mosquitoes are captured in the remaining trap. This gives an arithmetic mean of 50. On the next trapping day, 200 mosquitoes are captured in the first 9 traps and only 100 mosquitoes in the tenth trap with a resulting arithmetic mean of 30. The arithmetic mean or average from the second light trap sample of the population seemingly reflects a decrease in the number of mosquitoes present when actually populations quadrupled over most of the survey area. A population upsurge in one area of the base may indicate where specific control efforts should be directed but it must not be allowed to exert undue influence or cause alarm when the results from the entire complement of traps are viewed overall and over a reasonable period of time*. Continued increases in the number of mosquitoes over a period of a week or more and in the majority of traps warrant careful attention and action.

*Calculation of a geometric mean using logarithms will dampen the disruptive effect of a single large collection; however, for most installations this extra step is not necessary. Contact OL AD/ES if you are interested in learning more about geometric means.

C. Interpretation of Graphs of Trapping Data

a. Genetic variability and the resulting environmental tolerances of species and individuals within species will enable a few hardy specimens to emerge early in the mosquito season. These specimens may be captured with surveillance devices and will produce the first few, small, erratic peaks on the charts.

b. The early population fluctuations shown on the graphs will generally be followed by steadily rising plots as environmental conditions become more suitable for mosquito development. The rapidly climbing lines on the graphs indicate increasing numbers of captured mosquitoes which are part of the first vernal or spring mass emergence.

c. Twin peaks as appear on the STI plot for Culex tritaeniorhynchus in Figure 8 could indicate the emergence of 2 generations of the species (versus 1 peak and 1 generation for Anopheles sinensis in the same Figure), or such a graph may result from weather influence, trap malfunctions, or other factors like an invasion of the base by mosquitoes from an adjacent, heavily infested area.

d. Breaks in the graphs would indicate periods when trapping was not attempted. Graphs which fall to the zero population level would mean trapping was attempted but no specimens were captured. This in turn might have been caused by excessive winds, rain, other natural phenomena, or mechanical problems such as loss of electrical power, burned out bulbs, or motor failure.

e. The day-to-day success of base mosquito control efforts can be judged from the subsequent peaks or valleys on the trapping data graphs which indicate the effect of the control effort on the mosquito populations. The actual numbers of mosquitoes or the calculated indices should be transmitted to CE with notification of the locations where counts are rising. A marked decrease in the number of mosquitoes present, reflected in significant dips in the plots of the mosquito trap counts, is desired after fogging or ULV misting or other massive area treatment programs. Circumstances such as storms or the arrival of a cold front can give false indications of control.

f. The descending trapping data plots which occur toward the end of the mosquito season usually signal the autumnal decrease in mosquito populations. This is related to lower temperatures, less favorable breeding conditions, reduction in food availability, a significant drop in the number of adults carrying over from earlier generations, and a decrease in the number of new adults emerging to replace older ones that die.

V. MOSQUITO CONTROL

A. General. There are many practicable measures for mosquito control including physical, mechanical, biological, and chemical approaches. Ditching, proper storm drainage, landscaping, and filling are physical actions that can eliminate standing water and stop mosquito production. Vegetation control aids mosquito control: minimizing aquatic and emergent vegetation as well as debris in ditches and streams increases water flow and evaporation and lessens chances for standing water and mosquito breeding, and mowing grass and trimming back base perimeter vegetation minimizes resting sites for adult mosquitoes near human habitations. Screening buildings, removing discarded vehicle tires, cans, and other potential water collectors, and cleaning rain gutters are helpful mechanical actions. Natural mosquito parasites and predators like certain protozoa, nematodes, fungi, top-feeding fish, dragonflies, and other insects can exert noticeable natural control on mosquito populations and bacterial insecticides (Bactimos^R, Teknar^R, VectoBac^R) are commercially available for larval mosquito management. Chemical insecticidal measures are discussed below. Additional chemical control measures such as monomolecular organic surface films (Arosurf^R) are available for local purchase. Personal protective measures to lessen mosquito biting include use of mosquito repellents applied to the skin, repellent-treated cloth mesh jackets and tents, Permanone^R aerosol for clothing application to kill/repel mosquitoes, wear of long-sleeved shirts and long pants, and limiting outdoor crepuscular and nighttime activities to avoid peak mosquito biting periods.

B. Insecticidal Control. Individuals can release indoor space sprays of D-Phenothrin (2%) pyrethroid insecticide from aerosol cans in aircraft (disinsection), quarters, and other locations for temporary control of flying mosquitoes. All mosquito control, with the exception of required aircraft disinsections, like most other pest control must be justified by prior surveillance which documents the extent of the pest/vector problem. Figure 9 is a table of published recommendations for mosquito larvicides and adulticides including residual treatments and outdoor ultra low volume (ULV) space treatments. Dursban 2(%) Coated Granules for larviciding, Clarke 1.5 lb (Dursban) Mosquitocide Fogging Concentrate, and bendiocarb (Ficam^R) ULV are a few newer products. ULV space treatment is currently the most frequently employed mosquito control technique at most installations and deserves further discussion. Truck-mounted ULV cold aerosol generators saturate an area with insecticide in micron-sized (10-15 u optimum) droplets which remain diffused in the air and able to contact flying mosquitoes for some time before settling. The insecticidal fogging is a temporary mosquito control measure and usually must be accomplished repetitively every 24 to 48 hours based on surveillance findings. Ground-based ULV control trigger numbers of 20-30 female mosquitoes per trap per night are generally employed at most installations based on historical connection between rising number of complaint calls due to mosquito annoyance and rising trap counts; however, each local installation situation is unique with different pestiferous mosquito species, different mosquito-borne disease potential, varying medical and other command concern, and other variables which must be considered in establishing action thresholds. For most mosquito species, outdoor space

treatments are most effective when applied in crosswind swaths within the period from sunset to sunrise, when surface winds are 8 MPH or less, temperature is between 65°F and 85°F, and there is no rainfall. Diurnally active (day-flying Aedes) species are an exception which require control during daylight hours. The proper insecticide application rate and vehicle speed recommended on the insecticide label must be strictly adhered to, ULV vehicles are required to have passenger cab air conditioners, operators wear respirators, and an emergency spill containment kit is carried on the fogging vehicle. Technical malathion is disseminated by the majority of bases for mosquito adulticiding. Aerial ULV and other aerial insecticide applications offer rapid, wide area mosquito control, provided trained/certified air spray crews and specially equipped spray aircraft are available, and aerial applications may be justified under certain disease outbreak or pest infestation situations. AFR 91-22, Aerial Dispersal of Pesticides, discusses air spray validation statements, environmental assessments, and other prespray requirements.

Figure 9. Chemical Control Measures*+x

Larvicides

<u>Insecticide</u>	<u>Formulation or Application Rate</u>
methoprene (Altosid ^R)	3-4 fl oz of 10% EC/acre; 7.9% briquet
temephos (Abate ^R)	45.1% EC; 1, 2, 5% granular
chlorpyrifos (Dursban ^R)	0.4 - 1.6 fl oz of 44.4% EC/acre
Arosurf ^R MSF	0.2 - 0.5 gal/surface area

Adulticides - Outdoor Space Treatment

malathion	91% ULV, 2.6 - 3.0 fl oz/acre
chlorpyrifos (Dursban ^R)	61.5% ULV, 0.005 - 0.01 lb/acre

Outdoor Residual Treatment

malathion	4.5 fl oz of 57% Emulsifiable Concentrate/gal water (2% finished concentration); apply to shrubs, lower trees, and lawns
chlorpyrifos (Dursban ^R)	44.4% EC, 0.8 - 1.6 fl oz/Ac
propoxur (Baygon ^R)	13.9% EC, 8 fl oz/gal (1.1% finished concentration), apply to screens, doors, window frames, and other mosquito congregation surfaces.
carbaryl (Sevin ^R)	0.33 - 1.25 lb of 80% wettable powder/acre. Spray shade trees, shrubs, grass and buildings where mosquitoes congregate

Adulticide - Indoor Space Treatment

d-Phenothrin	2% (active ingredient) aerosol

*Source: Navy DVECC Pocket Guide to Pest Management, November 1984, pp 48-50.

+Always consult the label and adhere to host country regulations.

*PACAF Sup 1, AFR 161-1, requires CE Entomology report monthly to SG mosquito control efforts including dates control was accomplished, operations involved (larviciding, fogging, residual applied to vegetation, and so on), locations treated, and insecticides used.

VI. MOSQUITO BIONOMICS

The table below presents bionomic information on selected mosquito species in the Pacific area:

<u>Mosquito Species</u>	<u>Larval Habitats</u> ¹	<u>Biting Period</u> ²	<u>Hosts</u> ³	<u>Flight Range</u> ⁴	<u>Diseases Transmitted</u> ⁵
Aedes					
aegypti	AC, RH, SS, TH	D(N)	H, Z	.2 km	C, D
albopictus	AC, LA, RH, TH	D(N)	H, Z	1 km	C, D, DI, (JBE)
poicilius	AC, LA	N	H, Z	.2 km	BF
togoi	AC, RH, SM	N(D)	H, Zs	1 km	MF, (BF)
vexans	AC, DD, FS, FW, GP, RF, SM, WP	N(D)C	H, Z	9 km	BF
vexans nipponii	CW, DD, FW, GP, GRP, LM, SE	N(D)	Z, H	----	JBE
Anopheles					
balabacensis	FS, GRP, WP, SE	N, C(D)	H, Z	.1 km	M
flavirostris	DD, GS, GP, GRP, LM, SE	N	Z, H	2 km	BF, M, MF
lesteri	DD, FS, GP, GRP, LM, RF, SE	N	Z, H	----	M
minimus	DD, FS, GP, RF, SE	N	H, Z	----	M, (BF)
sinensis	DD, FW, GRP, RF, SE	N	Z, H	1 km	M, BF, MF
subpictus	AC, CS, CW, DD, FS, GP, GRP, RF	N	Z, H	6 km	M, BF, (JBE)
Culex					
bitaeniorhynchus	CW, DD, FS, GRP, RF, RH, SE	N, C	B, Z, H	----	BF, S, (JBE)
fuscocephala	AC, CW, DD, FS, GRP, LA, RF, TH	N	Z, B, H	1.4 km	JBE, BF
pipiens pallens	AC, DD, GRP	N	H, B, Z	----	JBE, BF
pseudovishnui	CW, GRP, RF	N	B, Z, H	----	JBE
quinquefasciatus	AC, CW, DD, GRP, SCB	N	H, Z, B	5 km	BF, MF, DI, (C), (JBE)
tritaeniorhynchus	AC, CW, DD, FS, GRP, RF, SM	N	Z, B, H	2 km	JBE, C, S
vishnui	GRP, LM, RF	N	Z, B, H	----	JBE, S
whitmorei	FS, GP, GRP, RF, SE	N	H, Z	----	BF, JBE
Mansonia					
uniformis	FS, SE	N, D, C	Z, H, Zs	----	BF, MF

¹AC = Artificial containers; CS = coastal swamp; CW = carabao wallow; DD = drainage ditch; FS = freshwater swamp/marsh; FW = flood waters; GP = grassland pool; GRP = ground pools; LA = leaf axils; LM = lake/pond margins; RF = ricefields; RH = rock holes; SCB = sewer catch basins; SE = stream edges; SM = saltwater marsh; SS = snail shells; TH = tree holes; WP = woodland pools (primary habitat underlined).

²C = crepuscular (dusk and dawn); D = day; N = night. (Parentheses = biting reported in some areas.)

³B = birds; H = humans; Z = Zoophilic (large mammals); Zs = Zoophilic (small mammals).

⁴Values given are estimates of maximum normal flight ranges.

⁵BF = Bancroftian filariasis; C = Chikungunya fever; D = dengue, dengue hemorrhagic fever; DI = Dirofilaria immitis; JBE = Japanese B encephalitis; M = malaria; MF = Malayan filariasis; S = Sindbis virus. Parentheses indicate disease agent for which the species is a secondary vector.
