A three-dimensional finite element model of a high power, low frequency ring-shell flextensional transducer (Sparton of Canada, Ltd., Model 34A0610) was developed for use with the ATILA code. This transducer model is to be coupled with an analytical acoustic field description in order to model a dense sonar array of US Navy interest. The three-dimensional model was derived from a two-dimensional model provided by the Naval Undersea Warfare Center. Two types of finite-element analyses were performed using ATILA: (1) an in-air modal analysis, in which the eigenfrequencies and eigenmodes are computed, and (2) an in-water harmonic analysis, in which the pressure field at a desired frequency is computed. The frequency of the ring mode computed for the three-dimensional model in the modal analysis was found to be 5 percent higher than the corresponding value for the two-dimensional model. From the harmonic analyses, the maximum sound pressure level on the acoustic axis was found to be 4 dB higher than the manufacturer's measured value and is located at exactly the same frequency.

ABSTRACT

A three-dimensional finite element model of a high power, low frequency ring-shell flextensional transducer (Sparton of Canada, Ltd. Model 34A0610 [Ref. 1]) was developed for use with the ATILA code [Ref. 2]. This transducer model is to be coupled with an analytical acoustic field description in order to model a dense sonar array of US Navy interest [Ref. 3].

The three-dimensional model was derived from a two-dimensional model provided by the Naval Undersea Warfare Center [Ref. 4]. Two types of finite-element analyses were performed using ATILA: (1) an in-air modal analysis, in which the eigenfrequencies and eigenmodes are computed, and (2) an in-water harmonic analysis, in which the pressure field at a desired driving frequency is computed. The frequency of the ring mode computed for the three-dimensional model in the modal analysis was found to be 5 percent higher than the corresponding value for the two-dimensional model. From the harmonic analyses, the maximum sound pressure level on the acoustic axis was found to be 4 dB higher than the manufacturer's measured value and is located at exactly the same frequency.

ACKNOWLEDGMENTS

I would like to thank Professor Steven Baker for his outstanding guidance, encouragement, support and dedication, Professor Ron Pieper for his recommendations and thesis revisions, and Professor Bryan Wilson for inviting me to do this work, for teaching me the basics of sonar transducer theory and design, for doing the final thesis revision, and for transmitting to me an incomparable example of complete dedication to the education and research causes.

Special thanks are due to Doctor Bernard Hamonic, from l'Institut Superieur d'Electronique du Nord in France, for his assistance with the ATILA code and finite element modeling, to John Blottman, from Naval Undersea Warfare Center, New London, for providing the Sparton ring-shell two-dimensional model, and to Sparton of Canada Ltd. for permitting the publication of this work without restrictions.

Gratitude is also expressed to my colleague Major Tay Tiong Beng, from Republic of Singapore Navy, for doing some drawings and for his assistance with the word processor.

Finally a very special thanks to my wife Vera for typing this thesis, for her encouragement, and for her understanding.

I. INTRODUCTION

The direction of active sonar surveillance systems is toward lower frequencies, requiring arrays of large, high power transducers. The successful design and operation of such arrays requires the ability to predict reliably their performance.

To this end, Professor S. R. Baker of the Physics Department, and Professors D. R. Canright and C. L. Scandrett from the Mathematics Department of the Naval Postgraduate School have established a research program with the goal of developing the means to predict the performance of arbitrarily dense, volumetric active sonar arrays [Ref. 3]. The approach used is based on the T-matrix method, which has been successfully applied to solve multiple scattering problems [Ref. 5]. In the present application, the acoustic field external to an arbitrary collection of radiators (here a radiator is a transducer surrounded by fluid to some arbitrary radius) is represented as a superposition of free-space radiation eigenfunctions (spherical harmonics). For each individual radiator a transition matrix, or T-matrix, is computed, which relates the expansion coefficients of outgoing waves to those of incoming waves and the driving

voltage. This requires the results of two harmonic finite element analyses, the free-field radiation problem and the single element scattering problem. Ultimately, the T-matrix of the total configuration, relating the far-field pressure to the driving voltage applied to each element, is obtained in terms of the T-matrix of the individual elements and translation matrices (of the spherical functions) that depend on the distance between and relative orientation of pairs of elements.

This thesis is concerned with the application of the finite-element code "ATILA", developed at the Institut Supérieur d'Electronique du Nord (Lille, France) [Ref. 2] to provide a three-dimensional model of a low frequency flextensional transducer of US Navy interest, the Model 34A0610 "ring-shell" transducer, manufactured by Sparton of Canada, Ltd. [Ref. 1], illustrated in Fig. 1. This transducer was used for proof of principle tests of the so-called "billboard" array concept, which is illustrated in Fig. 2. The results of harmonic radiation and scattering analyses performed using ATILA with the three-dimensional model will be used to generate the single-element T-matrix for this transducer, and so enable the billboard array to be modeled using the modified T-matrix method. The solution of the radiation problem is described in this thesis. The solution of the scattering problem can not be performed at this time. It will be performed using the same three-dimensional model as

Figure 1 Sparton Flextensional Transducers. From Ref. 1.

Figure 2 "Billboard" Array Concept.

for the radiation problem as soon this capability is available in ATILA.

A two-dimensional (axisymmetric) model of the ring-shell transducer was developed by the Naval Undersea Warfare Center [Ref. 4]. This model contains 285 elements, 825 nodes, and 1026 degrees-of-freedom. However, an axisymmetric model is not sufficient for modeling a dense array, since all modes of vibration (symmetric and anti-symmetric) can be excited by the incoming pressure field generated by neighboring transducers. A three-dimensional model is necessary.

A three-dimensional model is considerably more complex and requires far more computational time and computer memory. There is, however, a limit of 3000 degrees-of-freedom imposed by our version of the ATILA code. This limitation means that it is not feasible to obtain a three-dimensional model of the ring-shell transducer by a simple rotation of the axisymmetric model about its axis of symmetry. Instead, a simplified three-dimensional model with an acceptable engineering accuracy was pursued.

The remainder of this thesis is divided into six chapters. Chapter II describes the theory involved with the finite element analysis of piezoelectric transducers. Chapter III describes the transducer in question. Chapter IV discusses finite element model design considerations and the characteristics of the three-dimensional model. Chapter V presents and discusses the results of in-air modal analyses

and in-water harmonic analyses. Chapter VI presents the conclusions. Appendix A contains a copy of the input data file for the most refined mesh used in the harmonic analyses.

II. THEORY

A. FINITE ELEMENT ANALYSIS, THE ATILA CODE

The application of finite element analysis (FEA) to solve boundary value problems consists of the transformation of the governing differential or integral equation(s) into a multi-nodal matrix equation, the solution of which represents the discretized solution of the problem. There are many techniques to obtain a finite element formulation [Refs. 6,7,8,9].

ATILA is a finite element code developed at Institut Supérieur d'Electronique du Nord (ISEN) in France for the analysis of underwater transducers. It utilizes the variational formulation of the finite element problem [Refs. 10,11,12,13,14].

ATILA uses quadratic isoparametric elements. Isoparametric means the same polynomial (quadratic) is used to interpolate both geometry and field variation.

ATILA has 46 different types of elements. There are shell, plate, transition, spring, trilaminar, and two- and three-dimensional isoparametric elements of various geometries. It is possible to model elastic, piezoelectric, magnetostrictive, magnetic and composite materials, fluids, solid-fluid interfaces, and radiation dampers.

ATILA can perform: (1) static analyses, (2) modal analyses, which correspond to a free vibration problem, where the eigenfrequencies and eigenmodes are computed, and (3) harmonic analyses of radiation or scattering problems, which correspond to a forced vibration problem, the excitation being the voltage applied across the electrical terminals of the transducer or external forces applied to the nodes.

B. HARMONIC ANALYSIS OF A RADIATING PIEZOELECTRIC TRANSDUCER

This problem is governed by the equations of motion in the elastic and piezoelectric structures, by Poisson's Equation in the piezoelectric structures, and by Helmholtz's Equation in the fluid. Appropriate boundary conditions are defined, both on the solid-fluid interface and over the external fluid boundary, which must simulate the appropriate radiation condition.

The solid equation of motion is given by [Refs. 13,18,19]:

$$\rho \frac{\partial^2 u_i}{\partial t^2} = \frac{\partial \sigma_{ij}}{\partial x_j} \quad (1)$$

where ρ is the solid material density, u is the displacement vector, t is time, $[\sigma]$ is the stress tensor, and x_j is a coordinate direction. Here i and j can be 1, 2 and 3, and the Einstein notation is used, where summation is implied over repeated indices in the same term.

Poisson's Equation is given by [Refs. 13,18,19]:

$$\frac{\partial D_i}{\partial x_i} = 0 \quad (2)$$

where D is the electric displacement vector and x_i is a coordinate direction; i can be 1, 2 and 3.

The linearized, lossless Helmholtz Equation for the propagation of sound in fluids is given by [Ref. 15]:

$$\nabla^2 p - \frac{1}{c^2} \frac{\partial^2 p}{\partial t^2} = 0 \quad (3)$$

where ∇^2 is the three-dimensional Laplacian operator, p is the acoustic pressure, and t is time.

In piezoelectric materials the stress tensor and the electric displacement vector can be related to the strain tensor and the electric field vector and its material properties using the following constitutive equations, which neglect magnetic and pyroelectric effects [Refs. 13,18,19]:

$$\sigma_{ij} = c_{ijkl}^E S_{kl} - e_{kij} E_k \quad (4)$$

$$D_i = e_{ikl} S_{kl} + \epsilon_{ij}^S E_j \quad (5)$$

where $[\sigma]$ is the stress tensor, $[S]$ is the strain tensor, E is the electric field vector, D is the electric displacement

vector, $[c^E]$ is the constant electric field elastic stiffness tensor, $[e]$ is the piezoelectric tensor, and $[\epsilon^S]$ is the constant strain dielectric tensor; i, j, k and l can be equal to 1, 2 and 3.

Ultimately the solution is desired in terms of displacements and electric potentials. To this end the following two equations from elasticity and electricity, respectively, are used [Refs. 13,18,19]:

$$S_{ij} = \frac{1}{2} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) \quad (6)$$

$$E_i = - \frac{\partial \Phi}{\partial x_i} \quad (7)$$

where $[S]$ is the strain tensor, u is the displacement vector, x_i is a coordinate direction, E is the electric field vector and Φ is the electrical potential; i and j can be equal to 1, 2 and 3.

The boundary conditions and prescribed excitations at each node can be defined either by a displacement or an applied force, an electrical potential or an electrical charge, or an acoustic pressure.

In ATILA, the previous seven equations are transformed into the following matrix equation [Refs. 2,11,12,14]:

$$\begin{bmatrix} [K_{uu}] - \omega^2 [M] & [K_{u\phi}] & -[L] \\ [K_{u\phi}]^T & [K_{\phi\phi}] & [0] \\ -\rho^2 c^2 \omega^2 [L]^T & [0]^T & [H] - \omega^2 [M_1] \end{bmatrix} \begin{bmatrix} U \\ \Phi \\ P \end{bmatrix} = \begin{bmatrix} F \\ -q \\ \rho c^2 \Psi \end{bmatrix} \quad (8)$$

where the variables are defined as:

- U : vector of the nodal values of the components of the displacement field,
- Φ : vector of the nodal values of the electrical potential,
- P : vector of the nodal values of the pressure field,
- F : vector of the nodal values of the components of the externally applied forces,
- q : vector of the nodal values of the externally applied electrical charges,
- Ψ : vector of the nodal values of the integrated normal derivative of the externally applied pressure field (proportional to the externally applied flux),
- $[K_{uu}]$: stiffness matrix,
- $[K_{u\phi}]$: piezoelectric matrix,
- $[K_{\phi\phi}]$: dielectric matrix,
- $[M]$: consistent mass matrix,
- $[H]$: fluid (pseudo-) stiffness matrix,

$[M_f]$: consistent fluid (pseudo-) mass matrix,
 $[L]$: coupling matrix at the fluid structure interface,
 $[0]$: zero matrix,
 ω : angular frequency,
 ρ : fluid density,
 c : fluid sound speed,

and the superscript T represents the matrix transpose.

The results of this analysis for each input frequency are the complex displacement, rotation, and electrical potential fields at each transducer node, the complex pressure field at each fluid node, and the complex electrical impedance and admittance.

C. MODAL ANALYSIS OF A PIEZOELECTRIC TRANSDUCER

This problem is governed by the equations of motion in the elastic and piezoelectric structures, and by Poisson's Equation in the piezoelectric structures. The matrix equation governing this problem is easily obtained from that described in the previous section. In a modal analysis there is no fluid and there are no external forces applied (the natural boundary conditions), so the third row and column of Eq. (8) become irrelevant, and F is replaced by 0, resulting in

$$\begin{bmatrix} [K_{uu}] - \omega^2 [M] & [K_{u\phi}] \\ [K_{u\phi}]^T & [K_{\phi\phi}] \end{bmatrix} \begin{bmatrix} U \\ \Phi \end{bmatrix} = \begin{bmatrix} 0 \\ -Q \end{bmatrix} \quad (9)$$

where the elements are as defined in Eq. (8).

In this equation the resonance condition, which corresponds to the electrical short-circuit condition, is obtained by setting $\Phi=0$. The anti-resonance condition, which corresponds to the electrical open-circuit condition, is obtained by setting $q=0$.

The results of this analysis are the eigenfrequencies and eigenmodes. The maximum number of modes, which must be specified by the user, is 100.

III. TRANSDUCER DESCRIPTION

The transducer modeled in this research project is the Model 34A0610 manufactured by Sparson of Canada, Ltd. [Ref. 1]. It is a depth-compensated, high power, low frequency type V flextensional transducer (so-called "ring-shell"). A cutaway view is shown in Fig. 3 [Ref. 1]. The motor element consists of a set of 144 plates of thickness-poled lead zirconate titanate ceramic of dimensions 8x8x1 cm separated by 72 steel wedges, arranged in a 0.8 m diameter ring [Ref. 4]. The ceramic plates are connected electrically in parallel and effectively poled tangentially. One ST 4340 steel thin shell (a spherical section) is fastened to each ring planar surface. The ring is wrapped on the outside by a fiberglass belt, which provides a compressive stress of 25-40 MPa [Ref. 4].

The main operational characteristics of the transducer are [Ref. 1]:

- a. Resonance Frequency, which corresponds to the maximum voltage response in water - 610 Hz;
- b. Source Pressure Level, which corresponds to the effective pressure on the acoustic axis, at resonance - 213 dB re 1 μ Pa at 1 meter (driven by 3000 volts rms);

- c. Efficiency, which is the ratio of the output acoustic power to the input electric power - 90 percent at resonance, 65 percent at the -6dB points;
- d. Operational Depth, which corresponds to the maximum depth where the performance of the transducer is not compromised - exceeds 400 m.

Figure 3 Cutaway view of the transducer. From Ref. 1.

IV. THREE-DIMENSIONAL MODEL

A. INTRODUCTION

As mentioned in Chapter I, the performance modeling of a dense sonar array by means of the T- matrix method requires the computation of the radiation and scattering of an individual transducer. This can be accomplished very accurately using finite element analysis (FEA); however a three-dimensional (3-D) model must be employed.

A 3-D finite element model of a flextensional transducer has an inherent complexity compared to a corresponding 2-D model. The major limitation is the number of degrees of freedom (DOF) available, which depends upon the computer used. A simple transformation of the available 2-D model into a 3-D model would represent roughly more than 10000 DOF just for the solid structure. This already exceeds the maximum allowed degrees of freedom on the MICROVAX VMS system, where the ATILA code is installed, and so is not feasible.

Consequently, the objective of this research became to develop the simplest 3-D model of the Sparton ring-shell transducer that could reproduce, within acceptable error limits when compared with experimental data, its pertinent electroacoustic properties.

B. CHARACTERISTICS OF THE MODEL

1. MATERIAL PROPERTIES

All material properties are included on the first page of Appendix A. The format is according to the ATILA user's manual [Ref. 2].

a. Piezoelectric ceramic

As described before, the transducer has 144 tangentially poled lead zirconate titanate ceramic plates separated by 72 steel wedges, arranged in a 0.8 m diameter ring. An illustration of this arrangement is shown in Fig. 4. In order to simplify the model, a homogeneous ring with material properties equivalent to an adequate combination of the ceramic and steel was used. This is illustrated in Fig. 5. These properties were provided to us by Blottman who obtained them from McMahon [Ref. 4]: "The smeared material properties were obtained by McMahon and Armstrong through in-air measurement of the segmented ring during various stages of assembly. The measurements consist of the resonance and anti-resonance frequencies and the electrical capacitance." These properties take into consideration the compression given by the fiberglass wrapping. The given ceramic properties include losses, but as will be noted later, the results of harmonic analyses that included losses yielded a pressure field about 100 times smaller than the corresponding experimental results.

Figure 4 Original ring-shell arrangement.

Figure 5 Smeared ring-shell arrangement.

To model the transducer with its actual polarization requires the use of a very large number of elements because of the mesh design requirements; therefore the polarization was switched to an equivalent axially-poled ring. The transformation of the polarization is obtained by a suitable exchange of the elastic, piezoelectric and dielectric tensors. The procedure is outlined in the ATILA user's manual [Ref. 2].

Note that the ATILA manual describes the transformation from tangential polarization to radial polarization, which is not the present case. An axial orientation was chosen here rather than a radial orientation in order to simplify the application of electrical boundary conditions. Because of this modification the results of harmonic analyses have to be modified as follows: (1) divide the displacement and pressure fields by the ratio of the circumferential length of a "smeared" piezoelectric element (which is equal to $1/144$ of the the ring circumferencial length) to its height, and (2) multiply the electrical impedance by the square of the same ratio. In the present case this ratio is 0.1958.

b. Fiberglass

To simplify the model the fiberglass wrapping was modeled as an equivalent shell; otherwise a considerable number of additional elements would be required.

c. Shells

Their actual material properties were used.

2. TYPES OF ELEMENTS

The following quadratic isoparametric elements, which are described in the ATILA User's Manual [Ref. 2], were used:

TABLE 1

Region	Element	Geometry
Piezoelectric ring	HEXA20P	20-node hexahedron
Shells	SHEL06C	6-node triangle
Fiberglass wrapping	QUAD08E	8-node quadrilateral
Interface solid-fluid	TRIA12I	2x6-node triangle
Interface solid-fluid	QUAD16I	2x8-node quadrilateral
Fluid	PRISM15F	15-node triangular base prism
Fluid	HEXA20F	20-node hexahedron
Radiation surface	TRIA06R	6-node triangle
Radiation surface	QUAD08R	8-node quadrilateral

3. CONSTRAINTS ON MESH DESIGN

Design of the mesh was guided by the following constraints:

a. Aspect ratio [Ref. 2]

The aspect ratio of each element should be not greater than 3, although 4 is considered an acceptable, though less conservative, value.

b. Internal angles [Ref. 2]

The internal angles of each elements should be not smaller than 45 degrees and not greater than 135 degrees, although 30 degrees and 150 degrees are considered, respectively, acceptable, though less conservative, values.

c. Element size [Ref. 2]

As ATILA utilizes quadratic interpolation functions, the size of each element must be not greater than one fourth of a wavelength at the highest frequency of interest.

d. Interelement compatibility

The mesh should be built in such a way that adjacent elements have adjoining sides with collocated nodes to ensure accurate interpolation at their interfaces.

e. Coupling of shell elements to solid elements

Unlike two-dimensional elements, ATILA does not provide three-dimensional transition elements to match solid (piezoelectric) and shell three-dimensional elements. To

perform harmonic analyses it was necessary to delete the rotational degrees-of-freedom (DOF) for the piezoelectric nodes, which means that a clamped condition, which is not quite realistic, was assumed between the shell and the piezoelectric ring. As will be seen later, as the mesh becomes more and more refined, this assumed boundary condition becomes less and less significant.

f. Radiation boundary elements [Ref. 2]

For in-water harmonic analyses (radiation problems) the fluid mesh outer limit must be spherical. This is required by the radiation elements available in the ATILA code. ATILA offers so-called monopole and dipole radiation damping elements. The latter includes not only the monopole term of the radiated field multipolar expansion, but also the dipole term. Dipolar damping elements were selected to terminate the fluid mesh because they provide a more accurate solution than the monopolar damping elements for the mesh employed.

A fluid mesh outer limit radius greater than the far-field distance is desirable to compute the acoustic source pressure level and to compare computed and measured acoustic pressure data. The boundary was placed at a radius R equal to 0.72 m from the transducer's acoustical center, which is beyond 3.5 times the far-field limit of the equivalent piston-like source at the resonance frequency [Ref. 16].

4. FINAL MESH DESIGNS

With the above constraints one coarse mesh was designed for each type of analysis to be performed: in-air modal and in-water harmonic. An in-air modal analysis requires only the transducer to be modeled. An in-water harmonic analysis requires in addition the surrounding fluid to be modeled. The transducer coarse mesh consists of 12 shell elements and 8 solid elements, totaling 250 DOF, and is shown in Fig. 6. The total coarse mesh, which includes the fluid, contains in addition, 20 interface elements, 72 fluid elements, and 28 radiating elements, totaling 1330 DOF. This mesh is shown in Fig. 7. Based on these meshes and using the pre-processor mesh generator MOSAIQUE [Ref. 2], two mesh refinements were obtained. The most refined transducer mesh, which is shown in Fig. 8, consists of 40 shell elements and 24 solid elements, totaling 557 DOF. The corresponding total mesh, which is shown in Fig. 9, contains, in addition, 56 interface elements, 176 fluid elements and 72 radiating elements, totaling 2868 DOF. The input data file of this mesh is given in Appendix A.

Figure 9 Total refined mesh.

V. RESULTS

A. IN-AIR MODAL ANALYSES

This analysis corresponds to a free vibration problem, where the eigenfrequencies and eigenmodes are computed. Three mesh grades were analysed. For each one, the first twenty eigenfrequencies and eigenmodes were calculated (including the rigid body ones). The following table, which includes the two-dimensional (2-D) model, summarizes some characteristics of each mesh, along with the resonance frequency of the mode of vibration shown in Fig. 10, which is the most important in operation.

TABLE 2

Mesh	Coarse	Inter- mediate	Refined	2-D Model
Nodes	86	202	350	191
Elements	20	56	180	42
DOF	250	730	1330	392
Micro Vax II CPU Time	580 sec	9 hr	24 hr	14 min
Frequency	1746 Hz	1098 Hz	1002 Hz	957 Hz

The dashed lines in Fig. 10 correspond to the rest position; the solid lines correspond to the displaced position. Note the opposite sense of the motion of the ring and shells.

Figure 10 Ring mode of vibration.

A comparison between the results of the ring mode frequency for the more refined 3-D mesh and the 2-D model shows that the first is 5 percent higher than the second. Notice from Table 2 that as the mesh becomes more and more refined, the ring mode natural frequency value approaches more closely the corresponding 2-D model value. This is in part due to the clamped condition between the shell and the piezoelectric ring, which is not quite right, and possibly because of the use of a limited number of elements to describe the shape of the shell.

B. IN-WATER HARMONIC ANALYSES

This analysis corresponds to a forced vibration problem, the excitation being the voltage applied across the electrical terminals of the transducer. Three mesh grades were analysed, now including not only the transducer elements, but the interface, fluid and radiating elements. Internal material losses are not included in this model because the results obtained with such losses included were found to be about 40 dB below the corresponding measured values. The reason for this is not known. It is a problem which appeared only in three-dimensional modeling; no such problem was observed for axisymmetric models. In any case, neglecting internal losses is not a serious deficiency, since radiation losses dominate.

The following table, which includes the two-dimensional model and the manufacturer's measured values, summarizes some characteristics of each mesh along with the maximum sound pressure level (SPL) in dB re $1\mu\text{Pa}$ at a distance of 1m on the acoustic axis when driven by 3000 Vrms at the corresponding frequency.

TABLE 3

Mesh	Coarse	Refined	More Refined	2-D Model	Measured
Nodes	392	972	1696	825	xxxx
Elements	140	360	706	285	xxxx
DOF	557	1501	2868	1026	xxxx
Micro Vax II CPU time	3 hrs	33 hrs	101 hrs	48 min	xxxx
SPL dB re 1 μ Pa	200	209	217	213	213
Frequency Hz	1108	662	610	628	610

The following plot depicts the transmitting voltage response curve obtained by ATILA along with the corresponding manufacturer's data. The model displays a higher peak sound pressure level (SPL) for the primary resonance than the actual transducer. This was expected, since internal material losses were not considered.

It can be observed also from FIG. 11 that the second resonance of the model occurs at a considerably higher frequency than for the actual device. As discussed before, the probable explanation for this is that even the most refined

mesh used is not refined enough to represent the transducer dynamical behavior completely. This is in part due to the clamped condition between the shell and the piezoelectric ring, which is not quite right.

Notice in Table 3 that as the mesh becomes more and more refined, the SPL and resonant frequency values approach more closely the corresponding measured values. An attempt was made to perform a harmonic analysis using a mesh which was more refined (4184 DOF). This was not successful, however; apparently the number of degrees-of-freedom exceeded the limit imposed by our copy of ATILA.

Figure 11 Transmitting voltage response curve at 1m on acoustic axis driven at 3000 Vrms.

Plots of electrical impedance versus frequency and impedance circle for the more refined model are depicted in Figs. 12 and 13, respectively. Finally, electrical admittance versus frequency and the admittance circle are shown in Figs. 14 and 15, respectively.

Figure 15 Admittance circle.

VI. CONCLUSIONS

A three-dimensional model of a ring-shell flextensional transducer was built. Although the model includes many necessary simplifications to handle the problem in the available MICROVAX VMS system, the model is successful in obtaining a maximum sound pressure level from the in-water harmonic analyses that differs by 4 dB from the measured value and is located exactly at the same frequency.

The model does not consider internal material losses because the ATILA code was not able to compute accurate results for the three-dimensional model in this case. These difficulties were not encountered with axisymmetric models.

The model was built for the purpose of computing the radiation and scattering properties of the Sparton ring-shell transducer, the results of which are to be combined with an acoustic field model in order to describe the performance of a dense sonar array. Thus far the model has been used to compute the radiation pressure field. It will be used to compute the scattered pressure field when this capability becomes available in ATILA.
