Certificate Information

The following Ada implementation was tested and determined to pass ACVC 1.11. Testing was completed on December 18, 1992.

Compiler Name and Version: TeleGen2™ Ada Cross Development System
for Sun-4 to e68k, Version 4.1c

Host Computer System: Sun Microsystems Sun-4/690
under SunOS Release 4.1.2

Target Computer System: Motorola MVME147S-1 (68030/68882
bare machine)

See Section 3.1 for any additional information about the testing environment.

As a result of this validation effort, Validation Certificate 921218I1.11304 is awarded to TeleSoft. This certificate expires 24 months after ANSI approval of ANSI/MIL-STD-1815B.

This report has been reviewed and is approved.

CHAPTER 1

INTRODUCTION

The Ada implementation described above was tested according to the Ada Validation Procedures [Pro92] against the Ada Standard [Ada83] using the current Ada Compiler Validation Capability (ACVC). This Validation Summary Report (VSR) gives an account of the testing of this Ada implementation. For any technical terms used in this report, the reader is referred to [Pro92]. A detailed description of the ACVC may be found in the current ACVC User's Guide [UG89].

1.1 USE OF THIS VALIDATION SUMMARY REPORT

Consistent with the national laws of the originating country, the Ada Certification Body may make full and free public disclosure of this report. In the United States, this is provided in accordance with the "Freedom of Information Act" (5 U.S.C. #552). The results of this validation apply only to the computers, operating systems, and compiler versions identified in this report.

The organizations represented on the signature page of this report do not represent or warrant that all statements set forth in this report are accurate and complete, or that the subject implementation has no nonconformities to the Ada Standard other than those presented. Copies of this report are available to the public from the AVF which performed this validation or from:

National Technical Information Service
5285 Port Royal Road
Springfield VA 22161

Questions regarding this report or the validation test results should be directed to the AVF which performed this validation or to:

Ada Validation Organization
Institute for Defense Analyses

1.3 ACVC TEST CLASSES

Compliance of Ada implementations is tested by means of the ACVC. The ACVC contains a collection of test programs structured into six test classes: A, B, C, D, E, and L. The first letter of a test name identifies the class to which it belongs. Class A, C, D, and E tests are executable. Class B and class L tests are expected to produce errors at compile time and link time, respectively.

The executable tests are written in a self-checking manner and produce a PASSED, FAILED, or NOT APPLICABLE message indicating the result when they are executed. Three Ada library units, the packages REPORT and SPRT13, and the procedure CHECK_FILE are used for this purpose. The package REPORT also provides a set of identity functions used to defeat some compiler optimizations allowed by the Ada Standard that would circumvent a test objective. The package SPRT13 is used by many tests for Chapter 13 of the Ada Standard. The procedure CHECK_FILE is used to check the contents of text files written by some of the Class C tests for Chapter 14 of the Ada Standard. The operation of REPORT and CHECK_FILE is checked by a set of executable tests. If these units are not operating correctly, validation testing is discontinued.

Class B tests check that a compiler detects illegal language usage. Class B tests are not executable. Each test in this class is compiled and the resulting compilation listing is examined to verify that all violations of the Ada Standard are detected. Some of the class B tests contain legal Ada code which must not be flagged illegal by the compiler. This behavior is also verified.

Class L tests check that an Ada implementation correctly detects violation of the Ada Standard involving multiple, separately compiled units. Errors are expected at link time, and execution is attempted.

In some tests of the ACVC, certain macro strings have to be replaced by implementation-specific values -- for example, the largest integer. A list of the values used for this implementation is provided in Appendix A. In addition to these anticipated test modifications, additional changes may be required to remove unforeseen conflicts between the tests and implementation-dependent characteristics. The modifications required for this implementation are described in section 2.3.

INTRODUCTION

For each Ada implementation, a customized test suite is produced by the AVF. This customization consists of making the modifications described in the preceding paragraph, removing withdrawn tests (see section 2.1) and, possibly some inapplicable tests (see Section 2.2 and [UG89]).

In order to pass an ACVC an Ada implementation must process each test of the customized test suite according to the Ada Standard.

1.4 DEFINITION OF TERMS

Ada Compiler	The software and any needed hardware that have to be added to a given host and target computer system to allow transformation of Ada programs into executable form and execution thereof.
Ada Compiler Validation Capability	The means for testing compliance of Ada implementations, consisting of the test suite, the support programs, the ACVC user's guide and the template for the validation summary (ACVC) report.
Ada Implementation	An Ada compiler with its host computer system and its target computer system.
Ada Joint Program Office (AJPO)	The part of the certification body which provides policy and guidance for the Ada certification system.
Ada Validation Facility (AVF)	The part of the certification body which carries out the procedures required to establish the compliance of an Ada implementation.
Ada Validation Organization (AVO)	The part of the certification body that provides technical guidance for operations of the Ada certification system.
Compliance of an Ada Implementation	The ability of the implementation to pass an ACVC version.
Computer System	A functional unit, consisting of one or more computers and associated software, that uses common storage for all or part of a program and also for all or part of the data necessary for the execution of the program; executes user-written or user-designated programs; performs user-designated data manipulation, including arithmetic operations and logic operations; and that can execute programs that modify themselves during execution. A computer system may be a stand-alone unit or may consist of several inter-connected units.

INTRODUCTION

Conformity	Fulfillment by a product, process or service of all requirements specified.
Customer	An individual or corporate entity who enters into an agreement with an AVF which specifies the terms and conditions for AVF services (of any kind) to be performed.
Declaration of Conformance	A formal statement from a customer assuring that conformity is realized or attainable on the Ada implementation for which validation status is realized.
Host Computer System	A computer system where Ada source programs are transformed into executable form.
Inapplicable test	A test that contains one or more test objectives found to be irrelevant for the given Ada implementation.
ISO	International Organization for Standardization.
Operating System	Software that controls the execution of programs and that provides services such as resource allocation, scheduling, input/output control, and data management. Usually, operating systems are predominantly software, but partial or complete hardware implementations are possible.
Target Computer System	A computer system where the executable form of Ada programs are executed.
Validated Ada Compiler	The compiler of a validated Ada implementation.
Validated Ada Implementation	An Ada implementation that has been validated successfully either by AVF testing or by registration [Pro92].
Validation	The process of checking the conformity of an Ada compiler to the Ada programming language and of issuing a certificate for this implementation.
Withdrawn test	A test found to be incorrect and not used in conformity testing. A test may be incorrect because it has an invalid test objective, fails to meet its test objective, or contains erroneous or illegal use of the Ada programming language.

CHAPTER 2

IMPLEMENTATION DEPENDENCIES

2.1 WITHDRAWN TESTS

The following tests have been withdrawn by the AVO. The rationale for withdrawing each test is available from either the AVO or the AVF. The publication date for this list of withdrawn tests is 02 August 1991.

E28005C	B28006C	C32203A	C34006D	C35508I	C35508J
C35508M	C35508N	C35702A	C35702B	B41308B	C43004A

CE2107I	CE2117A	CE2117B	CE2119B	CE2205B	CE2405A
CE3111C	CE3116A	CE3118A	CE3411B	CE3412B	CE3607B
CE3607C	CE3607D	CE3812A	CE3814A	CE3902B	

2.2 INAPPLICABLE TESTS

A test is inapplicable if it contains test objectives which are irrelevant for a given Ada implementation. Reasons for a test's inapplicability may be supported by documents issued by the ISO and the AJPO known as Ada Commentaries and commonly referenced in the format AI-ddddd. For this implementation, the following tests were determined to be inapplicable for the reasons indicated; references to Ada Commentaries are included as appropriate.

IMPLEMENTATION DEPENDENCIES

The following 201 tests have floating-point type declarations requiring more digits than `SYSTEM.MAX_DIGITS`:

C24113L..Y (14 tests)	C35705L..Y (14 tests)
C35706L..Y (14 tests)	C35707L..Y (14 tests)
C35708L..Y (14 tests)	C35802L..Z (15 tests)
C45241L..Y (14 tests)	C45321L..Y (14 tests)
C45421L..Y (14 tests)	C45521L..Z (15 tests)
C45524L..Z (15 tests)	C45621L..Z (15 tests)
C45641L..Y (14 tests)	C46012L..Z (15 tests)

C35404D, C45231D, B86001X, C86006E, and CD7101G check for a predefined integer type with a name other than `INTEGER`, `LONG_INTEGER`, or `SHORT_INTEGER`; for this implementation, there is no such type.

C35713B, C45423B, B86001T, and C86006H check for the predefined type `SHORT_FLOAT`; for this implementation, there is no such type.

C35713D and B86001Z check for a predefined floating-point type with a name other than `FLCAT`, `LONG_FLOAT`, or `SHORT_FLOAT`; for this implementation, there is no such type.

C45531M..P (4 tests) and C45532M..P (4 tests) check fixed-point operations for types that require a `SYSTEM.MAX_MANTISSA` of 47 or greater; for this implementation, `MAX_MANTISSA` is less than 47.

C45624A..B (2 tests) check that the proper exception is raised if `MACHINE_OVERFLOW` is `FALSE` for floating point types; for this implementation, `MACHINE_OVERFLOW` is `TRUE`.

B86001Y checks for a predefined fixed-point type other than `DURATION`; for this implementation, there is no such type.

CA2009C and CA2009F check whether a generic unit can be instantiated before its body (and any of its subunits) is compiled; this implementation creates a dependence on generic units as allowed by AI-00408 and AI-00506 such that the compilation of the generic unit bodies makes the instantiating units obsolete. (See section 2.3.)

CD1009C uses a representation clause specifying a non-default size for a floating-point type; this implementation does not support such sizes.

CD2A84A, CD2A84E, CD2A84I..J (2 tests), and CD2A84O use representation clauses specifying non-default sizes for access types; this implementation does not support such sizes.

IMPLEMENTATION DEPENDENCIES

The tests listed in the following table check that USE_ERROR is raised if the given file operations are not supported for the given combination of mode and access method; this implementation supports these operations.

Test	File Operation	Mode	File Access Method
CE2102D	CREATE	IN_FILE	SEQUENTIAL_IO
CE2102E	CREATE	OUT_FILE	SEQUENTIAL_IO
CE2102F	CREATE	INOUT_FILE	DIRECT_IO
CE2102I	CREATE	IN_FILE	DIRECT_IO
CE2102J	CREATE	OUT_FILE	DIRECT_IO
CE2102N	OPEN	IN_FILE	SEQUENTIAL_IO
CE2102O	RESET	IN_FILE	SEQUENTIAL_IO
CE2102P	OPEN	OUT_FILE	SEQUENTIAL_IO
CE2102Q	RESET	OUT_FILE	SEQUENTIAL_IO
CE2102R	OPEN	INOUT_FILE	DIRECT_IO
CE2102S	RESET	INOUT_FILE	DIRECT_IO
CE2102T	OPEN	IN_FILE	DIRECT_IO
CE2102U	RESET	IN_FILE	DIRECT_IO
CE2102V	OPEN	OUT_FILE	DIRECT_IO
CE2102W	RESET	OUT_FILE	DIRECT_IO
CE3102E	CREATE	IN_FILE	TEXT_IO
CE3102F	RESET	Any Mode	TEXT_IO
CE3102G	DELETE	-----	TEXT_IO
CE3102I	CREATE	OUT_FILE	TEXT_IO
CE3102J	OPEN	IN_FILE	TEXT_IO
CE3102K	OPEN	OUT_FILE	TEXT_IO

The following 16 tests check operations on sequential, direct, and text files when multiple internal files are associated with the same external file and one or more are open for writing; USE_ERROR is raised when this association is attempted.

CE2107B..E	CE2107G..H	CE2107L	CD2110B	CE2110D
CE2111D	CE2111H	CE3111B	CE3111D..E	CE3114B
CE3115A				

CE2203A checks that WRITE raises USE_ERROR if the capacity of the external file is exceeded for SEQUENTIAL_IO. This implementation does not restrict file capacity.

CE2403A checks that WRITE raises USE_ERROR if the capacity of the external file is exceeded for DIRECT_IO. This implementation does not restrict file capacity.

CE3304A checks that USE_ERROR is raised if a call to SET_LINE_LENGTH or SET_PAGE_LENGTH specifies a value that is inappropriate for the external file. This implementation does not have inappropriate values for either line length or page length.

CE3413B checks that PAGE raises LAYOUT_ERROR when the value of the page number exceeds COUNT'LAST. For this implementation, the value of COUNT'LAST is greater than 150000 making the checking of this objective impractical.

2.3 TEST MODIFICATIONS

Modifications (see section 1.3) were required for 23 tests.

The following tests were split into two or more tests because this implementation did not report the violations of the Ada Standard in the way expected by the original tests.

B71001Q	BA1001A	BA2001C	BA2001E	BA3006A
BA3006B	BA3007B	BA3008A	BA3008B	BA3013A

CA2009C and CA2009F were graded inapplicable by Evaluation Modification as directed by the AVO. These tests contain instantiations of a generic unit prior to the compilation of that unit's body; as allowed by AI-00408 and AI-00506, the compilation of the generic unit bodies makes the compilation unit that contains the instantiations obsolete.

BC3204C and BC3205D were graded passed by Processing Modification as directed by the AVO. These tests check that instantiations of generic units with unconstrained types as generic actual parameters are illegal if the generic bodies contain uses of the types that require a constraint. However, the generic bodies are compiled after the units that contain the instantiations, and this implementation creates a dependence of the instantiating units on the generic units as allowed by AI-00408 and AI-00506 such that the compilation of the generic bodies makes the instantiating units obsolete--no errors are detected. The processing of these tests was modified by re-compiling the obsolete units; all intended errors were then detected by the compiler.

CD1009A, CD1009I, CD1C03A, CD2A21C, CD2A22J, CD2A24A, and CD2A31A..C (3 tests) use instantiations of the support procedure Length_Check, which uses Unchecked_Conversion according to the interpretation given in AI-00590. The AVO ruled that this interpretation is not binding under ACVC 1.11; the tests are ruled to be passed if they produce Failed messages only from the instantiations of Length_Check--i.e., the allowed Report.Failed messages have the general form:

" * CHECK ON REPRESENTATION FOR <TYPE_ID> FAILED."

CHAPTER 3

PROCESSING INFORMATION

3.1 TESTING ENVIRONMENT

The Ada implementation tested in this validation effort is described adequately by the information given in the initial pages of this report.

For information about this Ada implementation system, see:

TeleSoft
5959 Cornerstone Court West
San Diego, CA 92121, USA
Tel: (619) 457-2700

Testing of this Ada implementation was conducted at the customer's site by a validation team from the AVF.

3.2 SUMMARY OF TEST RESULTS

An Ada Implementation passes a given ACVC version if it processes each test of the customized test suite in accordance with the Ada Programming Language Standard, whether the test is applicable or inapplicable; otherwise, the Ada Implementation fails the ACVC [Pro92].

For all processed tests (inapplicable and applicable), a result was obtained that conforms to the Ada Programming Language Standard.

PROCESSING INFORMATION

The list of items below gives the number of ACVC tests in various categories. All tests were processed, except those that were withdrawn because of test errors (item b; see section 2.1), those that require a floating-point precision that exceeds the implementation's maximum precision (item e; see section 2.2), and those that depend on the support of a file system -- if none is supported (item d). All tests passed, except those that are listed in sections 2.1 and 2.2 (counted in items b and f, below).

a) Total Number of Applicable Tests	3803	
b) Total Number of Withdrawn Tests	95	
c) Processed Inapplicable Tests	71	
d) Non-Processed I/C Tests	0	
e) Non-Processed Floating-Point Precision Tests	201	
f) Total Number of Inapplicable Tests	272	(c+d+e)
g) Total Number of Tests for ACVC 1.11	4170	(a+b+f)

3.3 TEST EXECUTION

A magnetic data cartridge with the customized test suite (see section 1.3) was taken on-site by the validation team for processing. The contents of the data cartridge were loaded to the host computer using networking facilities.

After the test files were loaded onto the host computer, the full set of tests was processed by the Ada implementation.

The tests were compiled and linked on the host computer. The executable images were transferred to the target computer system by a serial communications link, and run. The results were captured from the host computer system onto a magnetic data cartridge.

Test output, compiler and linker listings, and job logs were captured on a magnetic data cartridge and archived at the AVF. The listings examined on-site by the validation team were also archived.

Testing was performed using command scripts provided by the customer and reviewed by the validation team. See Appendix B for a complete listing of the processing options for this implementation. It also indicates the default options. The options invoked explicitly for validation testing during this test are given in the following section, which was supplied by the customer.

Compiler Option Information

B TESTS:

ada -O D -L <test_name>

Option	Description
ada	invoke Ada compiler
-O D	perform optimizations
-L	generate interspersed source-error listing
<test_name>	name of Ada source file to be compiled

Non-B Non-Family TESTS:

ada -O D -m <main_unit> -a <options_file> <test_name>

Option	Description
ada	invoke Ada compiler
-O D	perform optimizations
-m	produce executable code for <main_unit>
<main_unit>	name of main Ada compilation unit
-a	specify linker options file
<options_file>	name of linker options file
<test_name>	name of Ada source file to be compiled

Non-B Family TESTS:

ada -O D <test_name>
ald -a <options_file> <main_unit>

Option	Description
ada	invoke Ada compiler
-O D	perform optimizations
<test_name>	name of Ada source file to be compiled
ald	invoke linker
-a	specify linker options file
<options_file>	name of linker options file
<main_unit>	name of main Ada compilation unit

Compiler Option Information *continued*

LINK:

ald -a <options_file> <main_unit>

Option	Description
ald	invoke Linker
-a	specify linker options file
<options_file>	name of linker options file
<main_unit>	name of main Ada compilation unit

Optimization Level D:

The optimizer switch "-O D" turns on full optimization within the compiler. The following list is a set of optimizations performed:

- Removal of unnecessary temporaries
- Efficient catenation operations
- Null array comparison
- Optimized compatibility check
- Improved record layout
- Variant record sizes in arrays
- Aggregate literal initialization for composites
- Out parameter transformations
- Initialization templates for special record variants
- Optimal basic block ordering
- Optimized usage of expression intermediates
- Direct utilization of scalar targets
- Calculate sizes in storage units
- Optimize overlap setting
- Parameter reordering
- Arithmetic strength reduction
- Optimized composite operations
- Case statement generation
- Object code emission
- Full use of addressing modes
- Reach reduction
- Small composite values
- Boolean expression reduction
- Optimal subprogram ordering
- Semi-open inlining
- Interprocedural analysis
- Subprogram inlining
- Collection optimization
- Value propagation
- Range analysis and substitution
- Check removal
- Test Pushing
- Control flow and unreachable code elimination
- Check test pushing
- Dead code elimination
- Constant folding
- Common subexpression recognition
- Register allocation
- Reach reduction
- Lifetime minimization
- Loop invariant code motion
- Strength: reduction of loop induction variables
- Loop counter reduction
- Tail recursion elimination

```

=====
ph_147.opt
Example options file for VME147 targets.

```

```

Usage: This option file should be used when linking with
the phantom sublibrary. Programs that are linked
with this option file have a boot address as
indicated below. The phantom load module must be
downloaded to the target in addition to the
program load module. This option file assumes use
of a VME147 with at least 1 MB of memory when using
the serial line dbtk/rcvr.

```

	Memory Location	Size (bytes)	
		<hex>	<decimal>
Top of used memory (serial)	:100000 -->	-----	-----
	:	18000 =	98304

APPENDIX A

MACRO PARAMETERS

This appendix contains the macro parameters used for customizing the ACVC. The meaning and purpose of these parameters are explained in [UG89]. The parameter values are presented in two tables. The first table lists the values that are defined in terms of the maximum input-line length, which is the value for \$MAX_IN_LEN--also listed here. These values are expressed here as Ada string aggregates, where "V" represents the maximum input-line length.

Macro Parameter	Macro Value
\$MAX_IN_LEN	200 -- Value of V
\$BIG_ID1	(1..V-1 => 'A', V => '1')
\$BIG_ID2	(1..V-1 => 'A', V => '2')
\$BIG_ID3	(1..V/2 => 'A') & '3' & (1..V-1-V/2 => 'A')
\$BIG_ID4	(1..V/2 => 'A') & '4' & (1..V-1-V/2 => 'A')
\$BIG_INT_LIT	(1..V-3 => '0') & "298"
\$BIG_REAL_LIT	(1..V-5 => '0') & "690.0"
\$BIG_STRING1	'"' & (1..V/2 => 'A') & '"'
\$BIG_STRING2	'"' & (1..V-1-V/2 => 'A') & '1' & '"'
\$BLANKS	(1..V-20 => ' ')
\$MAX_LEN_INT_BASED_LITERAL	"2:" & (1..V-5 => '0') & "11:"
\$MAX_LEN_REAL_BASED_LITERAL	"16:" & (1..V-7 => '0') & "F.E:"
\$MAX_STRING_LITERAL	"CCCCCCC10CCCCCCCC20CCCCCCCC30CCCCCCCC40 CCCCCCCC50CCCCCCCC60CCCCCCCC70CCCCCCCC80 CCCCCCCC90CCCCCCCC100CCCCCCCC110CCCCCCCC120 CCCCCCCC130CCCCCCCC140CCCCCCCC150CCCCCCCC160 CCCCCCCC170CCCCCCCC180CCCCCCCC190CCCCCCCC199"

Compiler Command Options

This document describes the options available for invoking the TeleGen2 compiler (via the *ada* command) and the TeleGen2 linker (via the *ald* command).

1.1. ada (Ada Compiler)

The *ada* command invokes the TeleGen2 Ada Compiler. Unless you specify otherwise, the compiler's front end, middle pass, and code generator are executed each time the compiler is invoked. You may, however, invoke the front end only, to check for syntax and semantic errors.

The syntax of the *ada* command is shown below.

```
ada [<option>...] <input>
```

<option> One of the options available with the command. Compiler options fall into four categories.

Library search -l(ibfile, -t(emplib

Execution/output Enable debugging: -d(ebug
 Abort after errors: -E(rror_abort
 Run front end only: -e(rrors_only
 Suppress checks: -i(nhibit
 Keep source: -K(eep_source
 Keep intermediates: -k(eep_intermediates
 Compile, then link: -m(ain
 Optimize code: -O(ptimize, -G(raph, -I(nline
 Update library for multiple files: -u(pdate_invoke
 Include execution profile: -x(ecution_profile

Listing Output source plus errors: -L(ist
 Output errors: -F(ile_only_errs, -j(oin
 Error context: -C(ontext
 Output assembly: -S("asm_listing"

Other -q(quiet, -V(space_size, -v(erbose

<input> The Ada source file(s) to be compiled. It may be:

- One or more Ada source files, for example:

```
/user/john/example  

Prog_A.text  

c10src/calc_mem.ada  

calcio.ada myprog.ada  

*.ada
```

If more than one file is specified, the names must be separated by a space.

- A file containing names of files to be compiled. Such a file must have the extension ".ilf"; each name in the file must be on a separate line. It is generally wise to limit the number of files in the input list to 10 — 20 if all files contain specifications and to no more than 5 if all contain bodies (assuming one unit per file). You can find more information on using input-list files in the *TeleGen2 User Guide*.
- A combination of the above.

Compiler defaults. Compiler defaults are set for your convenience. In most cases you will not need to use additional options; a simple "ada <input>" is sufficient. However, options are included to provide added flexibility. You can, for example, have the compiler quickly check the source for syntax and semantic errors but not produce object code [-e(rrors_only)] or you can compile, bind, and link a main program with a single compiler invocation [-m(ain)]. Other options are provided for other purposes.

The options available with *ada* appear below in alphabetical order.

-C(ontext

When an error message is sent to *stderr*, it is helpful to see the lines of the source program that surround the line containing the error. These lines provide a context for the error in the source program and help to clarify the nature of the error. The -C option controls the number of source lines that surround the error. The format of the option is

-C <n>

where <n> is the number of source context lines output for each error. The default for <n> is 1. This parameter specifies the total number of lines output for each error (including the source line that contains the error). The first context line is the one immediately before the line in error; other context lines are distributed before and after the line in error.

-d(ebug

To use the debugger, you must compile and link with the -d(ebug option. This is to make sure that a link map and debugging information are put in the Ada library for use by the debugger. Using -d(ebug ensures that the intermediate forms and debugging information required for debugging are not deleted.

Performance note:

While the compilation time overhead generated by the use of -d(ebug is minimal, retaining this optional information in the Ada library increases the space overhead. To see if a unit has been compiled with the -d(ebug option, use the *als* command with the -X(tended option. Debugger

information exists for the unit if the "dbg_info" attribute appears in the listing for that unit.

-E(rror_abort)

The **-E(rror_abort)** option allows you to set the maximum number of errors (syntax errors and semantic errors) that the compiler can encounter before it aborts. This option can be used with all other compiler options.

The format of the option is

-E <n>

where **<n>** is the maximum number of errors allowed (combined counts of syntax errors and semantic errors). The default is 999; the minimum is 1. If the number of errors becomes too great during a compilation, you may want to abort the compilation by typing **<ctrl>-C**.

-e(rrors_only)

The **-e(rrors_only)** option instructs the compiler to perform syntactic and semantic analysis of the source program without generating Low Form and object code. That is, it calls the front end only, not the middle pass and code generator. This means that only front end errors are detected and that only the High Form intermediates are generated. Unless you use the **-k(eep_intermediates)** option along with **-e**, the High Form intermediates are deleted at the end of compilation; in other words, the library is not updated.

The **-e(rrors_only)** option is typically used during early code development where execution is not required and speed of compilation is important. Since only the front end of the compiler is invoked when **-e** is used, **-e** is incompatible with *ada* options that require processing beyond the front end phase of compilation. Such options include, for example, **-O(ptime)** and **-d(ebug)**. If **-e** is not used (the default situation), the source is compiled to object code (providing no errors are found). Object code is generated for the specification and body and inserted into the working sublibrary.

-F(ile_only_errs)

The **-F** option is used to produce a listing containing only the errors generated during compilation; source is not included. The output is sent to **<file>.l**, where **<file>** is the base name of the input file. If input to the *ada* command is an input-list file (**<file>.ilf**), a separate listing file is generated for each source file listed in the input file. Each resulting listing file has the same name as the parent file, except that the extension ".l" is appended. **-F** is incompatible with **-L**.

-G(graph

The -G(graph option is valid only with -O(ptimeize.

This option generates a call graph for the unit being optimized. The graph is a file containing a textual representation of the call graph for the unit being optimized. For each subprogram, a list is generated that shows every subprogram called by that subprogram. By default, no graph is generated.

The graph is output to a file named <unit>.grf, where <unit> is the name of the unit being optimized. The structure and interpretation of call graphs is addressed in the Global Optimizer chapter of the *TeleGen2 User Guide*.

-I(nline_list

The -I(nline_list option is valid only with -O(ptimeize.

This option allows you to inline subprograms selectively. The format of the option is

-I <file>

where <file> is a file that contains subprogram names. The file must contain subprogram names in a specific form as noted below.

- A list of subprograms to be inlined, each separated by a comma or line feed *then*
- A semicolon or a blank line *then*
- A list of subprograms that are not to be inlined, each separated by a comma or line feed

Tabs and comments are not allowed. If there is no semicolon or blank line, the subprograms are considered to be visible. If you have no visible units to inline, use a semicolon to mark the beginning of the hidden-subprogram list. Inline lists are commonly set up with one name per line.

Each subprogram name in the list is in the form shown below.

[<unit>.]<subprogram>

The unit name indicates the location of the subprogram declaration, not the location of its body. If a unit name is not supplied, any matching subprogram name (regardless of the location of its declaration) will be affected. For example, the list

test; testing.test

indicates that all subprograms named Test should be marked for inlining except for those declared in either the specification or the body of the compilation unit Testing.

The first list of subprograms will be processed as if there had been a pragma

Inline in the source for them. The second list of subprograms will negate any Inline pragmas (including those applied by the first list) and will also prevent any listed subprograms from being automatically inlined (see A/a suboption pair, in the discussion of -O(ptimize)).

The ability to exempt otherwise qualified subprograms from automatic inlining gives you greater control over optimization. For example, a large procedure called from only one place within a case statement might overflow the branch offset limitation if it were inlined automatically. Including that subprogram's name in the second list in the list file prevents the problem and still allows other subprograms to be inlined.

Since the Low Form contains no generic templates, pragma Inline must appear in the source in order to affect all instantiations. However, specific instantiations can be affected by the inline lists. The processing of the names is case insensitive.

If you do not use -I, the optimizer automatically inlines any subprogram that is: (1) called from only one place, (2) considered small by the optimizer, or (3) tail recursive. Such optimizations are explained in detail in the Global Optimizer chapter of the *TeleGen2 User Guide*.

-i(nhibit

The -i(nhibit option allows you to suppress, within the generated object code, certain run-time checks, source line references, and subprogram name information. The -i(nhibit option is equivalent to adding pragma Suppress_All to the beginning of the declarative part of each compilation unit in a file.

The format of the option is

```
-i <suboption>[...]
```

where <suboption> is one or more of the single-letter suboptions listed below. When more than one suboption is used, the suboptions appear together with no separators; for example, "-i ln".

- l [line_info]** Suppress source line information in object code.

By default, the compiler stores source line information in the object code. However, this introduces an overhead of 6 bytes for each line of source that causes code to be generated. Thus, a 1000-line package with no instantiations or inlining may have up to 6000 bytes of source line information.

When source line information is suppressed, exception tracebacks indicate the offset of the object code at which the exception occurs instead of the source line number.

- n [name_info] Suppress subprogram name information in object code.

By default, the compiler stores subprogram name information in object code. For one compilation unit, the extra overhead (in bytes) for subprogram name information is the total length of all subprogram names in the unit (including middle pass-generated subprograms), plus the length of the compilation unit name. For space-critical applications, this extra space may be unacceptable.

When subprogram name information is suppressed, the traceback indicates the offsets of the subprogram calls in the calling chain instead of the subprogram names.

- c [checks] Suppress run-time checks — elaboration, overflow, storage access, discriminant, division, index, length, and range checks.

While run-time checks are vital during development and are an important asset of the language, they introduce a substantial overhead. This overhead may be prohibitive in time-critical applications.

- a [all] Suppress source line information, subprogram name information, and run-time checks. In other words, a (=inhibit all) is equivalent to inc.

Below is a command that tells the compiler to inhibit the generation of source line information and run-time checks in the object code of the units in *sample.ada*.

```
ada -v -i lc sample.ada
```

-j(oin

The -j(oin option writes errors, warning messages, and information messages that are generated during compilation back into the source file. Such errors and messages appear in the file as Ada comments. The comments thus generated can help facilitate debugging and commenting your code. Unlike the other listing options (-L, -S, and -F), the -j option does not produce a separate listing, since the information generated is written into the source file.

-K(eep_source

This option tells the compiler to take the source file and store it in the Ada library. When you need to retrieve your source file later, use the `act` command.

-k(eep_intermediates

The `-k(eep_intermediates` option allows you to retain certain intermediate code forms that the compiler otherwise discards.

By default, the compiler deletes the High Form and Low Form intermediate representations of all compiled secondary units from the working sublibrary. Deletion of these intermediate forms can significantly decrease the size of sublibraries — typically 50% to 80% for multi-unit programs.

Some of the information within the intermediate forms may be required later, which is the reason `-k(eep_intermediates` is available with *ada*. For example, High Form is required if the unit is to be referenced by the Ada cross-referencer (*ax*). In addition, both the debugger and optimizer require information that is saved within intermediate forms.

To verify that a unit has been compiled with the `-k(eep_intermediates` option, use the *als* command with the `-X(tended` option. If the unit has been compiled with `-k`, the listing will show the attributes `high_form` and `low_form` for the unit.

-L(list

The `-L(list` option instructs the compiler to output a listing of the source being compiled, interspersed with error information (if any). The listing is output to `<file>.l`, where `<file>` is the name of the source file (minus the extension). If `<file>.l` already exists, it is overwritten.

If input to the *ada* command is an input-list file (`<file>.ilf`), a separate listing file is generated for each source file listed in the input file. Each resulting listing file has the same name as the parent file, except that the extension ".l" is appended. Errors are interspersed with the listing. If you do not use `-L` (the default situation), errors are sent to *stderr* only; no listing is produced. `-L` is incompatible with `-F`.

-l(libfile

The `-l(libfile` option is one of the two library-search options; the other is `-t(emplib`. Both of these options allow you to specify the name of a library file other than the default, *liblst.alb*. The two options are mutually exclusive.

The format of the `-l(libfile` option is

`-l <file>`

where `<file>` is the name of a library file, which contains a list of sublibraries and optional comments. The file must have the extension ".alb". The first sublibrary is always the working sublibrary; the last sublibrary is generally the basic run-time sublibrary. Note that comments may be included in a library file and that each sublibrary listed must have the extension ".sub".

-m(ain)

This option tells the compiler that the unit specified with the option is to be used as a main program. After all files named in the input specification have been compiled, the compiler invokes the the Ada linker to bind and link the program with its extended family. By default an "execute form" (EF) load module named <unit>.ef is left in the current directory.

The format of the option is

-m <unit>

where <unit> is the name of the main unit for the program. If the main unit has already been compiled, make sure that the body of the main unit is in the current working sublibrary.

Note: You may specify options that are specific to the binder/linker on the *ada* command line if you use the *-m(ain)* option. In other words, if you use *-m*, you may also use *-o*, *-a*, or any of the other *ald* options except *-Z("link_only")*. For example, the command

```
ada -v -m welcome -o new.ef -a .opt sample.ada
```

instructs the compiler to compile the Ada source file *sample.ada*, which contains the main program unit *Welcome*. After the file has been compiled, the compiler calls the Ada linker, passing to it the *-o* and *-a* options with their respective arguments. The *-a* option tells the linker to use the commands specified in the option file *.opt* to direct the linking process; an option file is required for linking. The linker produces an "execute form" load module of the unit, placing it in file *new.ef* as requested by the linker's *-o* option.

If you use an option with *-m(ain)* that is common to both *ada* and *ald*, the option serves for both compiling and linking. For example, using *-S* with "ada -m" produces two assembly listings--one from compilation, one from elaboration.

-O(ptimize)

The optimizer operates on Low Form, the intermediate code representation that is output by the middle pass of the compiler.

When used on the *ada* command line, *-O(imize)* causes the compiler to invoke the global optimizer during compilation; this optimizes the Low Form generated by the middle pass for the unit being compiled. The code generator takes the optimized Low Form as input and produces more efficient object code.

Note: We recommend that you do not attempt to compile with optimization until the code being compiled has been fully debugged and tested, because using the optimizer increases compilation time. Please refer to the *TeleGen2 User Guide* for information on optimizing strategies.

The format of the option is

`-O <suboptions>`

where `<suboptions>` is a string composed of one or more of the single-letter suboptions listed below. `<suboptions>` is required.

The suboptions may appear in any order (later suboptions supersede earlier suboptions). The suboption string must not contain any characters (including spaces or tabs) that are not valid suboptions. Examples of valid suboptions are:

`-O pR1A`

`-O pa`

Table of optimizer suboptions

P	[optimize with parallel tasks] Guarantees that none of subprograms being optimized will be called from parallel tasks. P allows data mapping optimizations to be made that could not be made if multiple instances of a subprogram were active at the same time.
p	[optimize without parallel tasks] Indicates that one or more of the subprograms being optimized might be called from parallel tasks. This is a "safe" suboption. DEFAULT
R	[optimize with external recursion] Guarantees that no interior subprogram will be called recursively by a subprogram exterior to the unit/collection being optimized. Subprograms may call themselves or be called recursively by other subprograms interior to the unit/collection being optimized.
r	[optimize without external recursion] Indicates that one or more of the subprograms interior to the unit/collection being optimized could be called recursively by an exterior subprogram. This is a "safe" suboption. DEFAULT
I	[enable inline expansion of subprograms] Enables inline expansion of those subprograms marked with an Inline pragma or introduced by the compiler. DEFAULT
i	[disable inline expansion] Disables all inlining.
A	[enable automatic inline expansion] If the I suboption is also in effect (I is the default), A enables automatic inline expansion of any subprogram not marked for inlining; that is, any subprogram that is (1) called from only one place, (2) considered to be small by the optimizer, or (3) tail recursive. If i is used as well, inlining is prohibited and A has no effect. DEFAULT
a	[disable automatic inline expansion] Disables automatic inlining. If i is used as well, inlining is prohibited and a has no effect.
M	[perform maximum optimization] Specifies the maximum level of optimization; it is equivalent to "PRIA". This suboption assumes that the program has no subprograms that are called recursively or by parallel tasks.
D	[perform safe optimizations] Specifies the default "safe" level of optimization; it is equivalent to "prIA". It represents a combination of optimizations that is safe for all compilation units, including those with subprograms that are called recursively or by parallel tasks.

-q(quiet

By default, information messages are output even if the `-v(erbose` option is not used. The `-q(quiet` option allows you to suppress such messages. Using `-v(erbose` alone gives error messages, banners, and information messages. Using `-v(erbose` with `-q(quiet` gives error messages and banners, but suppresses information messages. The option is particularly useful during optimization, when large numbers of information messages are likely to be output.

-S("asm listing"

The `-S` option instructs the compiler to generate an assembly listing. The listings are generated in the working directory. If more than one unit is in the file, separate listings are generated for each unit. The format of the option is

`-S <suboption>`

where `<suboption>` is either "a" or "e".

- a [assembly] Generate a listing that can later be used as input to an assembler. The assembly file is named `<unit>.s` if it is a body or `<unit>_.s` if it is a specification.
- e [extended] Generate a paginated, extended assembly listing that includes code offsets and object code. The assembly file is named `<unit>.e` if it is a body or `<unit>_.e` if it is a specification.

The listing generated consists of assembly code intermixed with source code as comments. If input to the `ada` command is an input-list file (`<file>.ilf`), a separate assembly listing file is generated for each unit contained in each source file listed in the input file. Since `-S` is also an `ald` option, if you use `-S` along with `-m(ain`, an assembly listing is also output during the binding process.

-t(emplib

The `-t(emplib` option is one of the two library-search options; the other is `-l(ibfile`. Both of these options allow you to select a set of sublibraries for use during the time in which the command is being executed. The two options are mutually exclusive.

The format of the `-t(emplib` option is

`-t <sublib>[,...]`

where `<sublib>` is the name of a sublibrary. The name must be prefaced by a path name if the sublibrary is in a directory other than the current directory. The first sublibrary listed is the working sublibrary by definition. If more than one sublibrary is listed, the names must be separated by a comma. Single or double quotes may be used as delimiters.

The argument string of the `-t`(`emplib` option) is logically equivalent to the names of the sublibraries listed in a library file. So instead of using

```
-l worklib.alb
```

you could use `-t`(`emplib`) and specify the names of the sublibraries listed in `worklib.alb` (separated by commas) as the argument string.

-u(`pdate` invoke)

The `-u`(`pdate` invoke) (short for “`-u`(`pdate` after invocation)”) option tells the compiler to update the working sublibrary only after all files submitted in that invocation of `ada` have compiled successfully. The option is therefore useful only when compiling multiple source files.

If the compiler encounters an error while `-u` is in effect, the library is not updated, even for files that compile successfully. Furthermore, all source files that follow the file in error are compiled for syntactic and semantic errors only.

If you do not use the `-u`(`pdate` lib) option, the library is updated each time one of the files submitted has compiled successfully. In other words, if the compiler encounters an error in any unit within a single source file, all changes to the working sublibrary for the erroneous unit and for all other units in that file are discarded. However, library updates for units in previous or remaining source files are unaffected.

Since using `-u` means that the library is updated only once, a successful compilation is faster with `-u` than without it. On the other hand, if the compiler finds an error when you've used `-u`, the library is not updated even when the other source files compile successfully. The implication is that it is better to avoid using `-u` unless your files are likely to be error free.

-V(`space` size)

The `-V`(`space` size) option allows you to specify the size of the working space for `TeleGen2` components that operate on library contents. The format of the option is

```
-V <value>
```

where the option parameter is specified in 1-Kbyte blocks; it must be an integer value. The default value is 4000. The upper limit is 2,097,152. Larger values generally improve performance but increase physical memory requirements. Please read the section on adjusting the size of the virtual space in Chapter 2 of *TeleGen2 Programmer's Reference Manual* for more information.

-v(erbose)

The `-v(erbose)` option is used to display messages that inform you of the progress of the command's execution. Such messages are prefaced by a banner that identifies the component being executed. If `-v` is not used, the banner and progress messages are not output. However, information messages such as those output by the optimizer may still be output whether `-v(erbose)` is used or not.

-x(ecution_profile)

The `-x(ecution_profile)` option is used to obtain a profile of how a program executes. The option is available with `ada`, `ald`, and `aopt`. Using `-x` with `ada` or `aopt` causes the code generator to insert special run-time code into the generated object. Using `-x` with `ald` causes the binder to link in the run-time support routines that will be needed during execution.

Important: If you have compiled any code in a program with the `-x(ecution_profile)` option, you must also use `-x` when you bind and link the program. Refer to the Profiler chapter of the *TeleGen2 User Guide* for more information on profiling.

1.2. *ald* (Ada Linker)

The Ada Linker is a component of the TeleGen2 system that allows you to link compiled Ada programs in preparation for target execution. The linker resolves references within the Ada program, the bare target run-time support library, and any imported non-Ada object code. To support the development of embedded applications, the linker is designed to operate in a variety of modes and to handle many types of output format.

The linker is invoked by the *ald* command; it can also be invoked with the *-m*(ain) option of the *ada* command. In the latter case the compiler passes appropriate options to the linker to direct its operation. The syntax of the *ald* command is shown below.

```
ald [<option>...] unit
```

<option> One of the options available with the command.

<unit> The name of the main unit of the Ada program to be linked.

Important: When using the *ald* command, the body of the main unit to be linked must be in the working sublibrary.

In the simplest case, *ald* takes two arguments — the name of the main unit of the Ada program structure that is to be linked and the name of a linker option file — and produces one output file, the complete load module produced by the linking process. The load module is placed in the directory from which *ald* was executed, under the name of the main unit used as the argument to *ald*.

Linker directives are communicated to the linker as options on the command line or as options entered via an option file. *Command-line options* are useful for controlling options that you are likely to change often. The default option settings are designed to allow for the simplest and most convenient use of the linker. Command-line options are discussed below. *Option-file options* are for specifying more complicated linker options, such as the specification of memory locations for specific portions of the code or data for a program. Option-file options are discussed in the *TeleGen2 User Guide*.

The options available with *ald* appear below in alphabetical order.

-A(rray_size)

This option specifies the amount of internal buffer space, in Kbytes, to be allocated for the linker. The format of the option is

```
-A <value>
```

where <value> is a value between 1 and 10. The default is 2. Use this option only as recommended by Customer Support.

-a(Additional options

The `-a` option specifies that `ald` is to process additional options obtained from a linker option file. The format of the option is

```
-a <file>
```

where <file> is a valid file specification and represents a file containing linker options. If no extension is given, the extension is considered to be ".opt". A sample linker option file is provided for each board supported in the product; it is named <board>.opt and exists in the respective *examples/<board>* subdirectory of \$TELEGEN2. An option file is necessary for linking; it is not necessary for binding.

An option file is set up with one command per line, with each command line having the form

```
<command> [<parameter>]
- or - <command>/<option> [<parameter>]
- or - <command>/<option><parameter>
```

Commands and options are case-insensitive. Comment characters (--) are allowed. Some typical command/option pairs are

```
define/<name>- locate/at- output/complete
```

Note that some commands allowed in an option file can be expressed at the command level. Command-line options always supercede option-file options. The commands in a linker option file are shown below.

```
define
  /<symbol_name>=<value>
  [/address]
input
  [/export_definitions]
  [/main | /spec | /body | /ofm]
  [/phantom | /working_sublib]
  [/nosearch] <unit>
locate
  [/control_section=
    constant | code | data | udata | map]
  [/component_name=<unit>
    [/spec | /body | /ofm]]
  [/at=<address>]
  [/in=<region>]
```

```

    [/after=<csect_name | comp_unit>]
    [/alignment=<value>]
map
    [/image] -Alt: -Mi
    [/include_locals] -Alt: -Ml
    [/excluded] -Alt: -Me
    [/width=<132 | 80>] -Alt: -Mn
    [/height=<50 | <value>>]
    [<file>]
output
    [/object_form=<unit>] -Alt: -o
    [/complete | /incomplete]
    [/load_module=<file>]
region
    /high_bound=<address>
    /low_bound=<address>
    [/unused] [<region>]
target <processor_name>
exit
quit

```

For more information on the syntax of the commands available in the linker option file, please refer to the Linker chapter of the *TeleGen2 User Guide*.

-B(ase)

This option is used to specify the start location of the linked output. The linker will locate non-absolute control sections in consecutive memory locations. All control sections are word aligned on the MC680X0. The format is

```
-B <addr>
```

where <addr> is a valid MC680X0 address. The address can be specified as a decimal (%Ddecimal), a hexadecimal (%Xhex), or a hexadecimal-based literal in Ada syntax (16#hex#). The default is hexadecimal (%Xhex).

If you specify neither the *-B* option nor an option file LOCATE command and the link is complete, the linker uses the default location value of address 0.

The *-B* option governs the location for any code, constant, or data section not covered by an option file LOCATE command. This option does not supercede any LOCATE options. *-B(ase)* is equivalent to a LOCATE option with no control section or component name specified.

-b(ind_only)

The *-b(ind_only)* option instructs the linker to not invoke the link phase—in other words, to generate elaboration code only. This option is particularly useful when you have adapted your own linker and want to use it in place of

the TeleGen2 linker. The option is incompatible with `-Z("link_only."`

-d(ebug

This option controls the generation of debug symbol information for use with the debugger. A program that is to be run with the debugger must be linked with the `-d(ebug` option. If supported by the chosen load module format, `-d(ebug` may also cause symbol information to be output in the load module. In the standard configuration of the TeleGen2 system, none of the outputs support symbol information in the load module.

-f(ormat

The `-f(ormat` option specifies the format of the output module. The syntax of the option is

`-f <suboption>`

where `<suboption>` is one of the following; `<suboption>` is required.

- C [Custom] The C suboption is reserved for modules the linker has been adapted to support. See your target's *Board Support Guide* for information on adaptation.
- E [Execute Form] This suboption tells the linker that the object module to be generated is in TeleSoft Execute Form (the default). The default extension for such an output file is ".ef".
- I [IEEE-695] This suboption tells the linker that the object module to be generated is in IEEE-695 format. The default extension for such an output file is ".i3e".
- S [S-record] This suboption tells the linker that the object module to be generated is in Motorola S-record format. The default extension for such an output file is ".sr".

If `-f` is not used, `E(xecute_form` is produced. Execute Form is the default output format generated by the linker and is suitable for use as input to the downloader/receiver.

-l(ibfile

The `-l(ibfile` option is one of the two library-search options; the other is `-t(emplib`. Both of these options allow you to specify the name of a library file other than the default, *liblst.alb*. The two options are mutually exclusive.

The format of the `-l(ibfile` option is

`-l <file>`

where `<file>` is the name of a library file, which contains a list of

sublibraries and optional comments. The file must have the extension ".alb". The first sublibrary is always the working sublibrary; the last sublibrary is generally the basic run-time sublibrary.

-M(ap

This option is used to request and control a link map listing. The link map listing is sent to

`<unit>.map`

where `<unit>` is the name of the main program unit (if present), the name specified as the command line parameter, or the name specified as the first INPUT option, modified as necessary to form a valid UNIX file specification. The format of the link map listing file is described in the Linker chapter of the *TeleGen2 User Guide*. The format of the option is

`-M [<suboption>[...]]`

where `<suboption>` is one or more of the following:

- e** [excluded] Insert a list of excluded subprograms into the link map listing.
- i** [image] Generate a memory image listing in addition to the map listing. The linker writes the image listing to the same file as the link map listing.
- l** [locals] Include local symbols in the link map symbol listing.
- n** [narrow] Limit the width of the link map to 80 characters (the default is 132).

If more than one of the above suboptions is used, they must appear together, with no spaces. For example:

`-M eil`

A `-M(ap` option specified on the command line supercedes a `MAP` command in an option file.

-S("asm listing"

The `-S` option is used to output an assembly listing from the elaboration process. The format of the option is

`-S <suboption>`

where `<suboption>` is either "a" or "e".

- a** [assembly] Generate a listing that can later be used as input to an assembler. The assembly file is named `<unit>_M.s`.

- e [extended] Generate a paginated, extended assembly listing that includes code offsets and object code. The assembly file is named <unit>_M.e.

-s(symbol_file)

This option produces a file that contains all of the global symbols used in the link. The name of the symbol file produced is <main>.sym, where <main> is the name of the main program unit. The symbol file provides you with a simple means of obtaining information about symbol names and values.

The symbol file is an ASCII file that contains one entry per line. Each entry has the format

```
NNNNNNNTAAAAAAAAAA
```

where

NNNNNNNN An 8-character ASCII representation of the value of the symbol.

T A 1-character ASCII representation of the type of unit in which the symbol was located. Three characters are allowed:

```
"-" => Ada_Unit
"*" => Ofm_Unit
"/" => Link time defined symbol
```

AAAAAAA The ASCII representation of the symbol (truncated, if necessary). A maximum of 200 characters is allowed.

-T(traceback)

The -T(traceback option allows you to specify the callback level for tracing a run-time exception that is not handled by an exception handler. The format of the option is

```
-T <n>
```

where <n> is the number of levels in the traceback call chain. The default is 15. The -T(traceback option is useful only if you receive an Unexpected Error Condition message. This information may help you diagnose the problem.

-t(emplib)

The -t(emplib option is one of the two library-search options; the other is -l(ibfile). Both of these options allow you to select a set of sublibraries for use during the time in which the command is being executed. The two options are mutually exclusive.

The format of the `-t`(`emplib` option is

`-t <sublib>[,...]`

where `<sublib>` is the name of a sublibrary. The name must be prefaced by a path name if the sublibrary is in a directory other than the current directory. The first sublibrary listed is the working sublibrary by definition. If more than one sublibrary is listed, the names must be separated by a comma. Single or double quotes may be used as delimiters.

The argument string of the `-t`(`emplib` option is logically equivalent to the names of the sublibraries listed in a library file. So instead of using

`-l worklib.alb`

you could use `-t`(`emplib` and specify the names of the sublibraries listed in `worklib.alb` (separated by commas) as the argument string.

-w("timeslice")

The `-w` option allows you to specify the slice of time, in milliseconds, in which a task is allowed to execute before the run time switches control to the first ready task having equal priority. This timeslicing activity allows for ~~periodic~~ round-robin scheduling among equal-priority tasks.

The format of the option is

`-w <value>`

where `<value>` is the timeslice quantum in milliseconds. If the value specified is 15, for example, the run time will check each 15 milliseconds to see if any tasks with a priority equal to that of the executing task are available to execute. If there are, the run time effects a context switch to the first such task.

The default is 0 (i.e., timeslicing is disabled). Please note that no run-time overhead is incurred when timeslicing is disabled.

-V(space size)

The `-V`(`space_size` option allows you to specify the size of the working space for TeleGen2 components that operate on library contents. The format of the option is

`-V <value>`

where the option parameter is specified in 1-Kbyte blocks; it must be an integer value. The default value is 4000. The upper limit is 2,097,152. Larger values generally improve performance but increase physical memory requirements. Please read the section on adjusting the size of the virtual space in Chapter 2 of *TeleGen2 Programmer's Reference Manual* for more information.

-v(erbose)

The **-v**(erbose) option is used to display messages that inform you of the progress of the command's execution. Such messages are prefaced by a banner that identifies the component being executed. If **-v** is not used, the banner and progress messages are not output.

-X(ception_show)

By default, unhandled exceptions that occur in tasks are not reported; instead, the task terminates silently. The **-X** option allows you to specify that such exceptions are to be reported. The output is similar to that displayed when an unhandled exception occurs in a main program.

-x(ecution_profile)

The **-x**(ecution_profile) option is used to obtain a profile of how a program executes. The option is available with *ada*, *ald*, and *aopt*. Using **-x** with *ada* or *aopt* causes the code generator to insert special run-time code into the generated object. Using **-x** with *ald* causes the binder to link in the run-time support routines that will be needed during execution. These run-time support routines record the profiling data in memory during program execution and then write the data to two host files, *profile.out* and *profile.dic*, via the download line as part of program termination. The files can then be used to produce a listing that shows how the program executes.

Important: If you have compiled any code in a program with the **-x**(ecution_profile) option, you must also use **-x** when you bind and link the program. Refer to the Profiler chapter of the *TeleGen2 User Guide* for more information on profiling.

-Y("task_stack")

The **-Y** option allows you to alter the size of the task stack. In the absence of a representation specification for task storage_size, the run time will allocate 4096 bytes of storage for each executing task. **-Y** specifies the size of the basic task stack. The format of the option is

-Y <value>

where **<value>** is the size of the task stack in 8-bit bytes. The default is 4096. A representation specification for task storage size overrides a value supplied with this option.

-y("stack_guard")

The **-y** option is used to specify the size of the stack guard. The stack-guard space is the amount of space allocated per task, from the task stack, to accommodate interrupts and exception-handling operations. The format of the option is

-y <value>

where <value> is the size of the stack-guard size in 8-bit bytes. The value given must be less than the task-stack size. The default is 1024 bytes; this is the amount allocated unless otherwise specified.

-Z("link_only"

This option tells the linker to skip the binding phase and go directly to the link step. It is useful for generating phantom links where the main program may not yet exist. Note: unlike other link options, the -Z option cannot be passed with "ada -m". The option is incompatible with -b(ind_only).

APPENDIX C

APPENDIX F OF THE Ada STANDARD

The only allowed implementation dependencies correspond to implementation-dependent pragmas, to certain machine-dependent conventions as mentioned in Chapter 13 of the Ada Standard, and to certain allowed restrictions on representation clauses. The implementation-dependent characteristics of this Ada implementation, as described in this Appendix, are provided by the customer. Unless specifically noted otherwise, references in this Appendix are to compiler documentation and not to this report. Implementation-specific portions of the package STANDARD, which are not a part of Appendix F, are given on the following page.

ATTACHMENT F: PACKAGE STANDARD INFORMATION

For this target system the numeric types and their properties are as follows:

SHORT_INTEGER:

size = 8
first = -128
last = +127

INTEGER:

size = 16
first = -32768
last = +32767

LONG_INTEGER:

size = 32
first = -2147483648
last = +2147483647

FLOAT:

size = 32
digits = 6
first = -3.40282E+38
last = +3.40282E+38
machine_radix = 2
machine_mantissa = 24
machine_emin = -125
machine_emax = +128

LONG_FLOAT:

size = 64
digits = 15
first = -1.79769E+308
last = +1.79769E+308
machine_radix = 2
machine_mantissa = 53
machine_emin = -1021
machine_emax = +1024

DURATION:

size = 32
delta = 2# 1.0# e-14
first = -86400

3.10. LRM Appendix F - Implementation-Dependent Characteristics

The Ada language definition allows for certain target dependencies. These dependencies must be described in the reference manual for each implementation. This section addresses each point listed in LRM Appendix F. Topics that require further clarification are addressed in the sections referenced in the summary.

3.10.1. (1) Implementation-dependent pragmas

TeleGen2 has the following implementation-dependent pragmas:

```
pragma Comment
pragma Export
pragma Images
pragma Interface_Information
pragma Interrupt
pragma Linkname
pragma No_Suppress
pragma Preserve_Layout
pragma Suppress_All
```

3.10.1.1. Pragma Comment

Pragma Comment is used for embedding a comment into the object code. The syntax is

```
pragma Comment ( <string_literal> );
```

where <string_literal> represents the characters to be embedded in the object code. Pragma Comment is allowed only within a declarative part or immediately within a package specification. Any number of comments may be entered into the object code by use of pragma Comment.

3.10.1.2. Pragma Export

Pragma Export enables you to export an Ada subprogram or object to either the C language or assembly. The pragma is not supported for Pascal or FORTRAN. The syntax is

```
pragma Export ( [ Name => ] <subprogram_or_object_name>
               [, [ Link_Name => ] <string_literal> ]
               [, [ Language => ] <identifier> ] );
```

The syntax and use of the pragma is explained in detail in Section 2.8.3.

3.10.1.3. Pragma Images

Pragma Images controls the creation and allocation of the image and index tables for a specified enumeration type. The syntax is

```
pragma Images(<enumeration_type>, Deferred);
```

```
pragma Images(<enumeration_type>, Immediate);
```

The syntax and use of the pragma is described in detail in Section 2.7.3.

3.10.1.4. Pragma Interface_Information

Pragma Interface_Information provides information for the optimizing code generator when interfacing non-Ada languages or doing machine code insertions. Pragma Interface_Information is always associated with a pragma Interface except for machine code insertion procedures, which do not use a preceding pragma Interface. The syntax of the pragma is

```
pragma Interface_Information
(Name,                -- Ada subprogram, required
 Link_Name,          -- string, default = ""
 Mechanism,          -- string, default = ""
 Parameters,         -- string, default = ""
 Regs_Clobbered); -- string, default = ""
```

Section 2.8.2.2 explains the syntax and usage of this pragma.

3.10.1.5. Pragma Interrupt

Pragma Interrupt is used for function-mapped optimizations of interrupts. The syntax is

```
pragma Interrupt (Function_Mapping);
```

The pragma has the effect that entry calls to the associated entry, on behalf of an interrupt, are made with a reduced call overhead. This pragma can only appear immediately before a simple accept statement, a while loop directly enclosing only a single accept statement, or a select statement that includes an interrupt accept alternative.

Pragma Interrupt is explained more fully in Sections 2.11, 2.11.8.2, and 2.11.8.4.

3.10.1.6. Pragma Linkname

Pragma Linkname was formerly used to provide interface to any routine whose name cannot be specified by an Ada string literal. Pragma Interface_Information should now be used for this functionality. Pragma Linkname is described here only in support of older code that may still use it.

Pragma Linkname takes two arguments. The first is a subprogram name that has been previously specified in a pragma Interface statement. The second is a string literal specifying the exact link name to be employed by the code generator in emitting calls to the associated subprogram. The syntax is

```
pragma Interface ( <language>, <subprog> );
pragma Linkname ( <subprog>, <string_literal> );
```

If pragma Linkname does not immediately follow the pragma Interface for the associated subprogram, a warning will be issued saying that the pragma has no effect.

A simple example of the use of pragma Linkname is

```
procedure Dummy_Access( Dummy_Arg : System.Address );
pragma Interface (assembly, Dummy_Access );
pragma Linkname (Dummy_Access, "_access");
```

3.10.1.7. Pragma No_Suppress

Pragma No_Suppress is a TeleGen2-defined pragma that prevents the suppression of checks within a particular scope. It can be used to override pragma Suppress in an enclosing scope. The pragma uses the same syntax and can occur in the same places in the source as pragma Suppress. The syntax is

```
pragma No_Suppress (<identifier> [, [ON =>] <name>]);
```

<identifier> The type of check you do not want to suppress.

<name> The name of the object, type/subtype, task unit, generic unit, or subprogram within which the check is to be suppressed. <name> is optional.

Section 2.3.2.2 explains the use of this pragma in more detail.

3.10.1.8. Pragma Preserve_Layout

The TeleGen2 compiler reorders record components to minimize gaps within records. Pragma Preserve_Layout forces the compiler to maintain the Ada source order of components of a given record type, thereby preventing the compiler from performing this record layout optimization.

The syntax of this pragma is

```
Pragma Preserve_Layout ( ON => <record_type> );
```

Preserve_Layout must appear before any forcing occurrences of the record type and must be in the same declarative part, package specification, or task specification. This pragma can be applied to a record type that has been packed. If Preserve_Layout is applied to a record type that has a record representation clause, the pragma only applies to the components that do not have component clauses. These components will appear in Ada source order after the components with component clauses.

3.10.1.9. Pragma Suppress_All

Suppress_All is a TeleGen2-defined pragma that suppresses all checks in a given scope. Pragma Suppress_All takes no arguments and can be placed in the same scopes as pragma Suppress.

In the presence of pragma Suppress_All or any other Suppress pragma, the scope that contains the pragma will have checking turned off. This pragma should be used in a safe piece of time-critical code to allow for better performance.

3.10.2. (2) Implementation-dependent attributes

TeleGen2 has the following implementation-dependent attributes:

- 'Offset (in MCI)
- 'Subprogram_Value
- 'Extended_Image
- 'Extended_Value
- 'Extended_Width
- 'Extended_Aft
- 'Extended_Digits
- 'Extended_Fore

3.10.2.1. 'Offset

'Offset yields the offset of an Ada object from its parent frame. This attribute supports machine code insertions as described in Section 2.12.2.2.

3.10.2.2. 'Subprogram_Value

This attribute is used by the TeleGen2 implementation to facilitate calls to interrupt support subprograms. The attribute returns the value of the record type Subprogram_Value defined in package System.

3.10.2.3. Extended attributes for scalar types

The extended attributes extend the concept behind the text attributes 'Image, 'Value, and 'Width to give the user more power and flexibility when displaying values of scalars. Extended attributes differ in two respects from their predefined counterparts:

1. Extended attributes take more parameters and allow control of the format of the output string.
2. Extended attributes are defined for all scalar types, including fixed and floating point types.

Named parameter associations are not currently supported for the extended attributes.

Extended versions of predefined attributes are provided for integer, enumeration, floating point, and fixed point types:

Integer	Enumeration	Floating Point	Fixed Point
'Extended_Image	'Extended_Image	'Extended_Image	'Extended_Image
'Extended_Value	'Extended_Value	'Extended_Value	'Extended_Value
'Extended_Width	'Extended_Width	'Extended_Digits	'Extended_Fore 'Extended_Aft

For integer and enumeration types, the 'Extended_Value attribute is identical to the 'Value attribute. For enumeration types, the 'Extended_Width attribute is identical to the 'Width attribute.

The extended attributes can be used without the overhead of including Text_IO in the linked program. The following examples illustrate the difference between instantiating Text_IO.Float_IO to convert a float value to a string and using Float'Extended_Image:

```
with Text_IO;
function Convert_To_String ( F1 : Float ) return String is
  Temp_Str : String ( 1 .. 6 + Float'Digits );
package Flt_IO is new Text_IO.Float_IO (Float);
begin
  Flt_IO.Put ( Temp_Str, F1 );
  return Temp_Str;
end Convert_To_String;
```

```
function Convert_To_String_No_Text_IO( F1 : Float ) return String is
begin
  return Float'Extended_Image ( F1 );
end Convert_To_String_No_Text_IO;
```

```
with Text_IO, Convert_To_String, Convert_To_String_No_Text_IO;
procedure Show_Different_Conversions is
  Value : Float := 10.03376;
begin
  Text_IO.Put_Line ( "Using the Convert_To_String, the value of
the variable is : " & Convert_To_String ( Value ) );
  Text_IO.Put_Line ( "Using the Convert_To_String_No_Text_IO,
the value is : " & Convert_To_String_No_Text_IO ( Value ) );
end Show_Different_Conversions;
```

3.10.2.3.1. Integer attributes

'Extended_Image

X'Extended_Image(Item,Width,Base,Based,Space_If_Positive)

Returns the image associated with Item as defined in Text_IO.Integer_IO. The Text_IO definition states that the value of Item is an integer literal with no underlines, no exponent, no leading zeros (but a single zero for the zero value), and a minus sign if negative. If the resulting sequence of characters to be output has fewer than Width characters, leading spaces are first output to make up the difference. (LRM 14.3.7:10,14.3.7:11)

For a prefix X that is a discrete type or subtype, this attribute is a function that may have more than one parameter. The parameter Item must be an integer value. The resulting string is without underlines, leading zeros, or trailing spaces.

Parameters

Item	The item for which you want the image; it is passed to the function. Required.
Width	The minimum number of characters to be in the string that is returned. If no width is specified, the default (0) is assumed. Optional.
Base	The base in which the image is to be displayed. If no base is specified, the default (10) is assumed. Optional.
Based	An indication of whether you want the string returned to be in base notation or not. If no preference is specified, the default (false) is assumed. Optional.
Space_If_Positive	An indication of whether or not a positive integer should be prefixed with a space in the string returned. If no preference is specified, the default (false) is assumed. Optional.

Examples

```
subtype X is Integer Range -10..16;
```

Values yielded for selected parameters:

X'Extended_Image (5)	= "5"
X'Extended_Image (5,0)	= "5"
X'Extended_Image (5,2)	= " 5"
X'Extended_Image (5,0,2)	= "101"

LRM Annotations

Integer attributes

X'Extended_Image(5,4,2)	- " 101"
X'Extended_Image(5,0,2,True)	- "2#101#"
X'Extended_Image(5,0,10,False)	- "5"
X'Extended_Image(5,0,10,False,True)	- " 5"
X'Extended_Image(-1,0,10,False,False)	- "-1"
X'Extended_Image(-1,0,10,False,True)	- "-1"
X'Extended_Image(-1,1,10,False,True)	- "-1"
X'Extended_Image(-1,0,2,True,True)	- "-2#1#"
X'Extended_Image(-1,10,2,True,True)	- " -2#1#"

'Extended_Value**X'Extended_Value(Item)**

Returns the value associated with Item as defined in Text_IO.Integer_IO. The Text_IO definition states that given a string, it reads an integer value from the beginning of the string. The value returned corresponds to the sequence input. (LRM 14.3.7:14)

For a prefix X that is a discrete type or subtype, this attribute is a function with a single parameter. The actual parameter Item must be of predefined type string. Any leading or trailing spaces in the string X are ignored. In the case where an illegal string is passed, a Constraint_Error is raised.

Parameter

Item A parameter of the predefined type string; it is passed to the function. The type of the returned value is the base type X. Required.

Examples

```
subtype X is Integer Range -10..16;
```

Values yielded for selected parameters:

```
X'Extended_Value("5")      = 5
X'Extended_Value(" 5")     = 5
X'Extended_Value("2#101#") = 5
X'Extended_Value("-1")     = -1
X'Extended_Value(" -1")    = -1
```

'Extended_Width**X'Extended_Width(Base, Based, Space_If_Positive)**

Returns the width for subtype of X. For a prefix X that is a discrete subtype, this attribute is a function that may have multiple parameters. This attribute yields the maximum image length over all values of the type or subtype X.

Parameters

- Base** The base for which the width will be calculated. If no base is specified, the default (10) is assumed. Optional.
- Based** An indication of whether the subtype is stated in based notation. If no value for based is specified, the default (false) is assumed. Optional.
- Space_If_Positive** An indication of whether or not the sign bit of a positive integer is included in the string returned. If no preference is specified, the default (false) is assumed. Optional.

Examples

```
subtype X is Integer Range -10..16;
```

Values yielded for selected parameters:

X'Extended_Width	= 3	- "-10"
X'Extended_Width(10)	= 3	- "-10"
X'Extended_Width(2)	= 5	- "10000"
X'Extended_Width(10, True)	= 7	- "-10#10#"
X'Extended_Width(2, True)	= 8	- "2#10000#"
X'Extended_Width(10, False, True)	= 3	- "16"
X'Extended_Width(10, True, False)	= 7	- "-10#10#"
X'Extended_Width(10, True, True)	= 7	- "10#16#"
X'Extended_Width(2, True, True)	= 9	- "2#10000#"
X'Extended_Width(2, False, True)	= 6	- "10000"

3.10.2.3.2. Enumeration type attributes**'Extended_Image****X'Extended_Image(Item,Width,Uppercase)**

Returns the image associated with Item as defined in Text_IO.Enumeration_IO. The Text_IO definition states that given an enumeration literal, it will output the value of the enumeration literal (either an identifier or a character literal). The character case parameter is ignored for character literals. (LRM 14.3.9:9)

For a prefix X that is a discrete type or subtype; this attribute is a function that may have more than one parameter. The parameter Item must be an enumeration value. The image of an enumeration value is the corresponding identifier, which may have character case and return string width specified.

Parameters

- | | |
|------------------|---|
| Item | The item for which you want the image; it is passed to the function. Required. |
| Width | The minimum number of characters to be in the string that is returned. If no width is specified, the default (0) is assumed. If the Width specified is larger than the image of Item, the return string is padded with trailing spaces. If the Width specified is smaller than the image of Item, the default is assumed and the image of the enumeration value is output completely. Optional. |
| Uppercase | An indication of whether the returned string is in upper case characters. In the case of an enumeration type where the enumeration literals are character literals, Uppercase is ignored and the case specified by the type definition is taken. If no preference is specified, the default (true) is assumed. Optional. |

Examples

```
type X is (red, green, blue, purple);
type Y is ('a', 'B', 'c', 'D');
```

Values yielded for selected parameters:

X'Extended_Image(red)	= "RED"
X'Extended_Image(red, 4)	= "RED "
X'Extended_Image(red, 2)	= "RED"
X'Extended_Image(red, 0, false)	= "red"
X'Extended_Image(red, 10, false)	= "red "
Y'Extended_Image('a')	= "'a'"
Y'Extended_Image('B')	= "'B'"
Y'Extended_Image('a', 6)	= "'a' "
Y'Extended_Image('a', 0, true)	= "'a'"

'Extended_Value**X'Extended_Value(Item)**

Returns the image associated with Item as defined in Text_IO.Enumeration_IO. The Text_IO definition states that it reads an enumeration value from the beginning of the given string and returns the value of the enumeration literal that corresponds to the sequence input. (LRM 14.3.9:11)

For a prefix X that is a discrete type or subtype, this attribute is a function with a single parameter. The actual parameter Item must be of predefined type string. Any leading or trailing spaces in the string X are ignored. In the case where an illegal string is passed, a Constraint_Error is raised.

Parameter

Item A parameter of the predefined type string; it is passed to the function. The type of the returned value is the base type of X. Required.

Examples

```
type X is (red, green, blue, purple);
```

Values yielded for selected parameters:

```
X'Extended_Value("red")           = red
X'Extended_Value(" green")         = green
X'Extended_Value("  Purple")       = purple
X'Extended_Value(" GreEn ")        = green
```

'Extended_Width**X'Extended_Width**

Returns the width for subtype of X.

For a prefix X that is a discrete type or subtype; this attribute is a function. This attribute yields the maximum image length over all values of the enumeration type or subtype X.

Parameters

There are no parameters to this function. This function returns the width of the largest (width) enumeration literal in the enumeration type specified by X.

Examples

```
type X is (red, green, blue, purple);  
type Z is (X1, X12, X123, X1234);
```

Values yielded:

```
X'Extended_Width   = 6  - "purple"  
Z'Extended_Width   = 5  - "X1234"
```

3.10.2.3.3. Floating point attributes

'Extended_Image**X'Extended_Image(Item,Fore,Aft,Exp,Base,Based)**

Returns the image associated with *Item* as defined in *Text_IO.Float_IO*. The *Text_IO* definition states that it outputs the value of the parameter *Item* as a decimal literal with the format defined by the other parameters. If the value is negative, a minus sign is included in the integer part of the value of *Item*. If *Exp* is 0, the integer part of the output has as many digits as are needed to represent the integer part of the value of *Item* or is zero if the value of *Item* has no integer part. (LRM 14.3.8:13, 14.3.8:15)

Item must be a Real value. The resulting string is without underlines or trailing spaces.

Parameters

- | | |
|--------------|--|
| Item | The item for which you want the image; it is passed to the function. Required. |
| Fore | The minimum number of characters for the integer part of the decimal representation in the return string. This includes a minus sign if the value is negative and the base with the '#' if based notation is specified. If the integer part to be output has fewer characters than specified by <i>Fore</i> , leading spaces are output first to make up the difference. If no <i>Fore</i> is specified, the default value (2) is assumed. Optional. |
| Aft | The minimum number of decimal digits after the decimal point to accommodate the precision desired. If the delta of the type or subtype is greater than 0.1, then <i>Aft</i> is 1. If no <i>Aft</i> is specified, the default (X'Digits-1) is assumed. If based notation is specified, the trailing '#' is included in <i>Aft</i> . Optional. |
| Exp | The minimum number of digits in the exponent. The exponent consists of a sign and the exponent, possibly with leading zeros. If no <i>Exp</i> is specified, the default (3) is assumed. If <i>Exp</i> is 0, no exponent is used. Optional. |
| Base | The base that the image is to be displayed in. If no base is specified, the default (10) is assumed. Optional. |
| Based | An indication of whether you want the string returned to be in based notation or not. If no preference is specified, the default (false) is assumed. Optional. |

Examples

```
type X is digits 5 range -10.0 .. 16.0;
```

Values yielded for selected parameters:

<code>X'Extended_Image(5.0)</code>	= " 5.0000E+00"
<code>X'Extended_Image(5.0,1)</code>	= "5.0000E+00"
<code>X'Extended_Image(-5.0,1)</code>	= "-5.0000E+00"
<code>X'Extended_Image(5.0,2,0)</code>	= " 5.0E+00"
<code>X'Extended_Image(5.0,2,0,0)</code>	= " 5.0"
<code>X'Extended_Image(5.0,2,0,0,2)</code>	= "101.0"
<code>X'Extended_Image(5.0,2,0,0,2,True)</code>	= "2#101.0#"
<code>X'Extended_Image(5.0,2,2,3,2,True)</code>	= "2#1.1#E+02"

'Extended_Value**X'Extended_Value(Item)**

Returns the value associated with Item as defined in Text_IO.Float_IO. The Text_IO definition states that it skips any leading zeros, then reads a plus or minus sign if present then reads the string according to the syntax of a real literal. The return value is that which corresponds to the sequence input. (LRM 14.3.8:9, 14.3.8:10)

For a prefix X that is a discrete type or subtype; this attribute is a function with a single parameter. The actual parameter Item must be of predefined type string. Any leading or trailing spaces in the string X are ignored. In the case where an illegal string is passed, a Constraint_Error is raised.

Parameter

Item A parameter of the predefined type string; it is passed to the function. The type of the returned value is the base type of the input string. Required.

Examples

```
type X is digits 5 range -10.0 .. 16.0;
```

Values yielded for selected parameters:

```
X'Extended_Value("5.0")           = 5.0  
X'Extended_Value("0.5E1")         = 5.0  
X'Extended_Value("2/1.01/E2")     = 5.0
```

'Extended_Digits**X'Extended_Digits(Base)**

Returns the number of digits using base in the mantissa of model numbers of the subtype X.

Parameter

Base The base that the subtype is defined in. If no base is specified, the default (10) is assumed. Optional.

Examples

type X is digits 5 range -10.0 .. 16.0;

Values yielded:

X'Extended_Digits - 5

3.10.2.3.4. Fixed point attributes**'Extended_Image****X'Extended_Image(Item,Fore,Aft,Exp,Base,Based)**

Returns the image associated with Item as defined in Text IO.Fixed IO. The Text IO definition states that it outputs the value of the parameter Item as a decimal literal with the format defined by the other parameters. If the value is negative, a minus sign is included in the integer part of the value of Item. If Exp is 0, the integer part of the output has as many digits as are needed to represent the integer part of the value of Item or is zero if the value of Item has no integer part. (LRM 14.3.8:13, 14.3.8:15)

For a prefix X that is a discrete type or subtype; this attribute is a function that may have more than one parameter. The parameter Item must be a Real value. The resulting string is without underlines or trailing spaces.

Parameters

- | | |
|-------------|---|
| Item | The item for which you want the image; it is passed to the function. Required. |
| Fore | The minimum number of characters for the integer part of the decimal representation in the return string. This includes a minus sign if the value is negative and the base with the '#' if based notation is specified. If the integer part to be output has fewer characters than specified by Fore, leading spaces are output first to make up the difference. If no Fore is specified, the default value (2) is assumed. Optional. |
| Aft | The minimum number of decimal digits after the decimal point to accommodate the precision desired. If the delta of the type or subtype is greater than 0.1, then Aft is 1. If no Aft is specified, the default (X'Digits-1) is assumed. If based notation is specified, the trailing '#' is included in Aft. Optional. |
| Exp | The minimum number of digits in the exponent; the exponent consists of a sign and the exponent, possibly with leading zeros. If no Exp is specified, the default (3) is assumed. If Exp is 0, no exponent is used. Optional. |
| Base | The base in which the image is to be displayed. If no base is specified, the default (10) is assumed. Optional. |

Based An indication of whether you want the string returned to be in based notation or not. If no preference is specified, the default (false) is assumed. Optional.

Examples

type X is delta 0.1 range -10.0 .. 17.0;

Values yielded for selected parameters:

X'Extended_Image(5.0)	= " 5.00E+00"
X'Extended_Image(5.0,1)	= "5.00E+00"
X'Extended_Image(-5.0,1)	= "-5.00E+00"
X'Extended_Image(5.0,2,0)	= " 5.0E+00"
X'Extended_Image(5.0,2,0,0)	= " 5.0"
X'Extended_Image(5.0,2,0,0,2)	= "101.0"
X'Extended_Image(5.0,2,0,0,2,True)	= "2#101.0#"
X'Extended_Image(5.0,2,2,3,2,True)	= "2#1.1#E+02"

'Extended_Value**X'Extended_Value(Image)**

Returns the value associated with Item as defined in Text_IO.Fixed_IO. The Text_IO definition states that it skips any leading zeros, reads a plus or minus sign if present, then reads the string according to the syntax of a real literal. The return value is that which corresponds to the sequence input. (LRM 14.3.8:9, 14.3.8:10)

For a prefix X that is a discrete type or subtype; this attribute is a function with a single parameter. The actual parameter Item must be of predefined type string. Any leading or trailing spaces in the string X are ignored. In the case where an illegal string is passed, a Constraint_Error is raised.

Parameter

Image Parameter of the predefined type string. The type of the returned value is the base type of the input string. Required.

Examples

```
type X is delta 0.1 range -10.0 .. 17.0;
```

Values yielded for selected parameters:

```
X'Extended_Value("5.0")           = 5.0
X'Extended_Value("0.5E1")         = 5.0
X'Extended_Value("2#1.01#E2")     = 5.0
```

'Extended_Fore**X'Extended_Fore(Base,Based)**

Returns the minimum number of characters required for the integer part of the based representation of X.

Parameters

- Base** The base in which the subtype is to be displayed. If no base is specified, the default (10) is assumed. Optional.
- Based** An indication of whether you want the string returned to be in based notation or not. If no preference is specified, the default (false) is assumed. Optional.

Examples

```
type X is delta 0.1 range -10.0 .. 17.1;
```

Values yielded for selected parameters:

```
X'Extended_Fore      = 3  -- "-10"  
X'Extended_Fore(2)  = 6  -- "10001"
```

'Extended_Aft**X'Extended_Aft(Base, Based)**

Returns the minimum number of characters required for the fractional part of the based representation of X.

Parameters

Base The base in which the subtype is to be displayed. If no base is specified, the default (10) is assumed. Optional.

Based An indication of whether you want the string returned to be in based notation or not. If no preference is specified, the default (false) is assumed. Optional.

Examples

```
type X is delta 0.1 range -10.0 .. 17.1;
```

Values yielded for selected parameters:

```
X'Extended_Aft      = 1  - "1" from 0.1  
X'Extended_Aft(2)  = 4  - "0001" from 2#0.0001#
```

end System;
```

3.10.3.1. System.Label

The System.Label meta-function is provided to allow you to address objects by a linker-recognized label name. This function takes a single string literal as a parameter and returns a value of System.Address. The function simply returns the run-time address of the appropriate resolved link name, the primary purpose being to address objects created and referenced from other languages.

- When used in an address clause, System.Label indicates that the Ada object or subprogram is to be referenced by a label name. The actual object must be created in some other unit (normally by another language), and this capability simply allows you to import that object and reference it in Ada. Any explicit or default initialization will be applied to the object. For example, if the object is declared to be of an access type, it will be initialized to NULL.
- When used in an expression, System.Label provides the link time address of any name, such as a name for an object or a subprogram.

3.10.3.2. System.Report_Error

`Report_Error` must be called from directly within an exception handler. This routine displays the normal exception traceback information to standard output. It is essentially the same traceback that could be obtained if the exception were unhandled and propagated out of the program. `Report_Error` simply allows you to handle the exception and still display this information. You may also want to use this capability in a user handler at the end of a task since exceptions in tasks will not be propagated to the main program. You can also get this capability for all tasks by using the `-X` binder switch.

For details on the output, refer to Section 2.9, "Exception handling."

3.10.4. (4) Restrictions on representation clauses

Representation clauses are fully supported with the following exceptions:

- Enumeration representation clauses are supported for all enumeration types except Boolean types.
- Record representation clauses are supported except for records with dynamically-sized components.
- `Pragma Pack` is supported except for dynamically-sized components.

3.10.5. (5) Implementation-generated names

TeleGen2 has no implementation-generated names.

3.10.6. (6) Address clause expression interpretation

An expression that appears in an object address clause is interpreted as the address of the first storage unit of the object.

3.10.7. (7) Restrictions on unchecked conversions

Unchecked programming is supported except for unchecked type conversions where the destination type is an unconstrained record or array type.

3.10.8. (8) Implementation-dependent characteristics of the I/O packages

`Text_IO` has the following implementation-dependent characteristics:

```
type Count is range 0..(2 ** 31)-2;
```

```
subtype Field is integer range 0..1000;
```

The standard run-time sublibrary contains preinstantiated versions of `Text_IO.Integer_IO` for types `Short_Integer`, `Integer`, and `Long_Integer`, and of `Text_IO.Float_IO` for types `Float` and `Long_Float`. Use the following packages to eliminate multiple instantiations of the `Text_IO` packages:

- `Short_Integer_Text_IO`
- `Integer_Text_IO`
- `Long_Integer_Text_IO`
- `Float_Text_IO`
- `Long_Float_Text_IO`

TeleGen2 for SPARC-E68
