## 1. Introduction

The Fast Adaptive Maneuvering Experiment (FAME) is designed to provide neural network (NN) researchers with a physical, non-linear system of modest dimensionality with coupled dynamics. The system to be controlled is a commercially available model electric helicopter (Whisper) which is secured to a commercially-available stand (Flitemaster Jr) which has been modified to limit its range of motion and make it suitable for laboratory operation. The stand has been instrumented with potentiometers to measure all 6 degrees-of-freedom (6-DOF). In order to make the interface to the system as simple as possible, a Motorola MC68HC11 microcontroller unit (MCU) has been employed to implement the RS-232 communications protocol, convert the voltages on the potentiometers into angles (8-bit quantization), perform the coordinate conversions to a Cartesian space, reply to requests from the NN controller for helicopter position, and translate commands from the NN controller into appropriate servo commands.

The source code for all of the software which has been developed for the MCU and the PC communications is provided with the stand so that local modifications can be made as needed. It is in a highly modularized form which allows easy modification once the underlying principle of the software design is understood. A modified commercial MCU board was used (Motorola M68HC11EVb) in order to minimize expenses and provide a limited development/software modification capability to individual researchers. The monitor program on the board has been left intact and can be accessed through the second serial port on the board using Kermit or other terminal emulation software. Actual software development was done using a PC-based C cross-compiler and cross-assembler which supports ANSI C.

The software on the MCU is resident in two forms. The Motorola Buffalo monitor is in its original form on ROM. The board has been modified to incorporate a 32-k byte SRAM with self-contained battery backup (nominal 10 year life). This memory was chosen to enable ease of local software modification as well as easy incorporation of updated software in the field. For all practical purposes, the lower half of memory is populated with non-volatile SRAM in which the program is stored. Conflicts with internal RAM and memory mapped registers are not a problem since the MC68HC11 accesses internal memory when it is available. With this approach, field changes can be made by

modifying the stored program directly through the Buffalo monitor rather than having to erase and reprogram erasable-programmable read only memories (EPROMS).

A calibration program is included as part of the software so that precise mechanical alignment of the stand is not required. If for some reason the stand has been disassembled and the potentiometers

Figure 1 Major system components.

moved, this program can be used to realign them in software. The user is prompted to put the movable parts of the stand in certain positions. The MCU then reads the potentiometers, calculates the new offsets and scale factors and stores them in on-chip nonvolatile SRAM. There is no need to recalibrate unless the stand is disassembled or the potentiometers moved from their calibrated positions.

Consideration was given to a number of *safeguards which could be incorporated in the MCU software*, but which have not been

implemented. It was felt that any "Deadman's Switch" included in the software would be too intrusive on the desires of NN researchers and limiting on the flexibility of their software design. The hazards of operation of this system should not be taken lightly and, at the very least, appropriate eyeware should be worn when operating the system.

## 2. Major Components

Three major **subsystems** comprise FAME: the stand, the helicopter, and the MCU interface. Each of these components **has been** modified to integrate them into a single system which can be controlled via requests and commands passed to it through an RS-232 interface. The following details the modifications which have been made to each as well as information which may be useful to those who are unfamiliar with model helicopter operations.

## 2.1. Stand

The stand is a modified commercially available Flitemaster Junior. This stand is usually used by the novice helicopter flyer to learn to hover and maneuver electric or small gas helicopters without the danger of crashing. Although the range of motion is limited, the stand can assist in the development of a pilot's mental framework and the eye-hand coordination necessary for control of this complex system.

The Flitemaster was chosen primarily because it had 6-DOF incorporated in the basic design. Although there are other stands available, this is the only one which has full 6-DOF. As purchased, the stand needs to be modified to make it suitable for NN control of the helicopter. Modifications to the stand are as follows:

1. All axes have been fitted with 5k Ohm linear potentiometers which are supplied with 5 Volts. The potentiometers' outputs are converted by the MCU's A/D converters for angular measurements.
2. A wheel has been added to support the lowest arm to relieve stress on the lowest joint (the center of the H-frame) and improve the accuracy of position measurements.
3. The nylon block support system at the helicopter end of the stand has been replaced with double roller-bearings in order to reduce friction and provide structural support and rigidity to the replacement shaft which supports the helicopter itself.
4. The final nylon-steel ball/socket helicopter support was replaced with an inverted metal joystick. The potentiometers on this joystick provide roll and pitch angle measurements. A difficulty associated with this support arrangement which has not been resolved is that the center of rotation is below the center of mass of the helicopter and therefore during takeoffs the helicopter platform must be supported to keep it level and stop rotation.
5. **Brackets** were added to hold the potentiometers which measure joint angles. In some cases, the brackets are also used to limit the range of motion of joints (primarily yaw and the lowest joint at the center of the H). These range limiting mechanisms must not be tampered with or the potentiometers (which do not have a full 360 degrees of motion) will be damaged. Shaft encoders could have been used to allow full range of motion, but this would have been at a significant expense which the budget would not

allow. If potentiometers are removed/replaced/adjusted, care must be taken to insure that they are secured in such a position that the full range of motion of the joint will not damage the potentiometer.

6. The spring support at the middle joint has been modified by changing springs and adding turnbuckles. Modifying the geometry of the springing is ineffective in compensating for the additional weight of the helicopter and MCU. Some compensation is made with the removal of the battery from the helicopter, but stronger springs are needed to mass balance the system.
7. Wiring has been added to provide electrical power to the MCU, power to the electric helicopter motor, and carry the joint potentiometer signals to the MCU's A/D for conversion.

The stand should be secured to the floor and an area cleared to insure unimpeded flight of the helicopter. If a permanent mounting cannot be made, two or more 25 lb bags of lead shot have been used to keep the H-frame immobile while the helicopter is flows.

## **2.2 Kalt Whisper Helicopter**

The helicopter is manufactured by Kalt and is commercially available as the Whisper. The helicopter and spare parts are available at local hobby shops. Because the Whisper utilizes an electric motor as power for the main rotor it must carry a nickel-cadmium (NICAD) battery on board for power. In order to carry this load, the frame is very light and therefore not very strong. It will not take much abuse. In particular, the ball links which actuate the controls are particularly easy to break and the use of ball-link pliers for disassembly is strongly encouraged.

The Whisper kits were purchased in almost-ready-to-fly (ARF) form. Experience has shown that the modest difference in price between the kit and the ARF kit is well worth the savings in construction time. The ARF kits have been completed and the helicopter adjusted and aligned. The helicopter construction manuals are delivered with FAME, but alignment is a tedious process and should not be necessary except in the event of mishap. In particular, do not remove the tape from the main rotor blade(s). This tape is used to balance the rotors as well as a sighting device when the blades are

aligned for proper tracking (both blades following the same path). Perfect tracking is difficult to obtain, and the systems are adjusted as close as possible when delivered.

There are two switches on the plate which supports the helicopter. The on/off switch supplies power to the electric speed controller. This switch is used in normal helicopter installations with radios to provide a regulated voltage to the radio receiver. There is a second switch, a push-button, which enables the speed controller to supply electricity to the motor. There are two switches in the normal hobby installation so that the radio receiver can be enabled and a check made to insure that the throttle is at such a setting that the motor will not turn when the motor is enabled. If power is not supplied to the MCU when the push button is enabled, unpredictable results will occur (the motor could start turning and hit the person actuating the button). Insure that the MCU is operating and that the green light is lit on the motor controller before pushing the button. The initial setting of the throttle by the MCU is at its minimum value.

#### 2.2.1. SERVOS

Ball bearing servos are used throughout to insure long life and reliability. The particular servos used are Futaba FPS-133. While the operation of the servos is transparent to the users, a brief explanation of the electrical mode of actuation follows. Each servo is controlled by a 5 Volt pulse of variable width. A pulse width of 1.0 ms positions the servo at an extreme end of its rotation. A pulse width of 2.0 ms positions the servo at the other extreme end of its rotation. The nominal zero for the servo occurs at a pulse width of 1.5 ms. The angle between these two extremes is proportional to the pulse width between 1.0 and 2.0 ms. The exact values are not given here since there are servo-servo differences and the linkage is not necessarily linear between the servo and the control actuated (usually rotary to linear motion conversion is involved with a limited range of linear operation). That is, the resultant amount of control action is not necessarily linearly related to the servo command.

The servo **does not** respond to a single pulse width command, but the command must be repeated at regular intervals to insure complete motion to the commanded angle. In order to relieve the NN controller of this burden, the MCU interface continuously sends the commanded pulse width to each servo. The software is designed such that a two bytes control word covers the complete range of motion of each servo. That is, the pulse width in units of 500 ns/unit are transmitted as unsigned

integers (e.g., 2000 decimal = 1.0 ms). The actual pulse width is generated using the output compare of the MC68HC11 and is a background process under the control of interrupts.

One servo is not mechanical and that is the speed controller. The format of the control signals for it is the same as the other servos, but it is solid-state and has no moving parts. This improves reliability as well as accuracy of control over other methods which have a mechanical servo controlling the position of a high current potentiometer. With this method, there is little wasted energy since the SS speed controller is operated in a switching mode. Normal model helicopter have a mixing function incorporated either on the helicopter or in the transmitter. This mixing function couples the throttle (SS speed controller) to the collective pitch. These are not coupled in the MCU implementation and are completely separate channels available for individual control.

### **2.2.2. GYRO**

There is one single-rate Futaba gyro mounted on the helicopter for yaw stabilization. The normal configuration for a yaw rate gyro is to have the tail rotor signal from the receiver (the 1.0 to 2.0 ms pulse) connected to the gyro. The gyro then modifies this pulse width according to yaw-dot to generate a yaw disturbance negative feedback signal. The Futaba model number of this special gyro for electric helicopters is Futaba G-155.

In the FAME configuration, the yaw rate gyro is driven by a 1.5 ms pulse from the MCU in response to a position measurement command from the workstation. The pulse-width gyro output is then read by the MCU and converted to an eight-bit signed value. This value can then be returned to the workstation along with the 6-DOF coordinates. Although the electrical connections are made on FAME, the software does not yet implement this function.

### **2.3. M68HC11 EVB**

Motorola sells an evaluation board based on its MC68HC11 microcontroller (MCU). This board was selected because of its low cost and inclusion of the port replacement unit (PRU). The PRU allows the MCU to be operated in the expanded mode (one of its four modes of operation) while retaining all of the original ports as if it were operating in the single-chip mode. Operation in the expanded mode

allows for the virtual memory (64 kbytes) to be fully populated with either RAM or ROM. The additional ROM is required because of an early decision to write as much code as possible in C in order to make it easier for the user to modify it to suit his particular needs. The printf() and scanf() functions in particular require a lot of space. These printing functions are primarily used when the optional monitor is attached and operating in a terminal mode.

An additional reason for using the evaluation board is that it comes with complete circuit diagrams as well as a complete hardware reference manual. Also bundled with it is a bare-bones cross-assembler (non-macro) which could be used in a pinch to make necessary modifications to the MCU code.

The board as it comes from the factory is stuffed with 8 kbytes of RAM at address \$C000 and this is retained. A SRAM of 32 kbytes is added to insure sufficient space for a high-level language program. The SRAM chosen has a built-in battery backup so that it retains its memory even when power is removed. The SRAM acts as if it were an EEPROM except that it is much easier to modify in that it only needs to be written to just like any other RAM. While EEPROM has a sufficiently short access time during operation, it has an unacceptably long programming time. Minor modifications are made to the board and the socket for an optional 8 kbyte RAM (\$6000) is used to hold the 32 kbyte SRAM. The following modifications are required to utilize the Dallas DS1230Y-150 32kx8 nonvolatile SRAM on the M68HC11EVB:

1. **Replace R2 (10 kOhm) with approximately 3.3k Ohm.** Smaller values will cause the M68HC11 to sink too much current. Larger values prevent the passive pullup from charging the input to the chip sufficiently fast. Occasional errors occur in memory if this is not done.

**Table I** Jumper settings for M68HC11EVB.

| Jumper Number | Setting                         |
|---------------|---------------------------------|
| 1             | Open                            |
| 2             | 2-3                             |
| 3             | Open                            |
| 4             | 1-2 (Buffalo)<br>2-3 (FAMEmain) |
| 5             | 9600                            |
| 6             | Closed                          |
| 7             | Open                            |

2. Disconnect Jumper J3 to disconnect chip select from chip select decoder. Address bit 15 is used as CS~ to select the lower half of memory.
3. Cut the trace to pin 11/U12E effectively removing R/W\* from pin 11.
4. Connect pin 11/U12E to pin 1/U12A effectively supplying the E-clock to pin 11.
5. Connect pin 20/U4 to pin35 of U10. This connects A15 to CS~ of the SRAM.
6. Cut the trace between pin 26/U4 and pin 28/U4.
7. Connect pin 26/U4 to pin 37/U10. This connects A13 to the SRAM.
8. Connect pin 1/U4 to pin 36/U10. This connects A14 to the SRAM.

The normal 8kx8 SRAM at \$C000 (U5) can be retained and is needed to run the calibrate program. The addition of the 32kx8 effectively fully populates the lower half of M68HC11 memory. Those memory addresses which are internal to the M68HC11 remain so and there is no conflict between the external SRAM and internal locations. The memory between \$4000 and \$5FFF may be unusable depending on whether you program modifies the SCI control flip-flop, U11B.

As delivered, the jumpers on the MC68HC11EVB board should be as listed in Table I.

All signal interconnections are made to the board through the 60 pin connector. Power (0 V, +5 V) is supplied to the 6-DOF potentiometers from the MCU board through an eight position Dean's connector female block. Ground and signal lines are supplied to the helicopter servos through another block. Plus 5 Volts is not supplied from the MCU board since excessive current drain during servo actuation causes the board to malfunction. Power is supplied to the servos from the speed controller servo (SCS) which has an internal regulator. The SCS regulates its +12 Volt supply voltage down to +5 volts and normally powers the receiver and servos. In FAME, this regulated +5 Volts is distributed to the servos through the servo connector block. A common ground is provided between the MCU and the SCS.

If it is desired to have an external restart button, pin 17 of the 60-pin connector can be extended off the stand along with a ground wire. Grounding pin 17 of the 60-pin connector will restart the board as long as jumper J1 is in place.

### 2.3.1. BUFFALO MONITOR

As delivered from Motorola, the evaluation board has a resident monitor called Buffalo. This monitor has a limited repertoire and is designed for hands on experimentation at a simple level. Since the monitor does allow some direct access to the MCU as well as the ability to download Motorola S-record format files, it has been maintained. Whether to restart in Buffalo or in the normal FAME operating program is determined by jumper J4. If connected between pins 1 and 2 restart causes Buffalo to come up. If J4 is connected between pins 2 and 3, then the FAMEMAIN program begins to execute after pushing the restart button.

Documentation for Buffalo is found in the evaluation board manual. When uploading S-record format files using Kermit, be sure to include the \0 on the transmit command so handshaking protocol is eliminated, e.g., "Transmit FAMEmain.0 \0". This does not appear to be a problem using PROCOMM in the ASCII file upload mode. Note that one uploads a file rather than downloads it to the MCU. Due to differences in the way operating system BIOSs handle CR/LF, FAME software was compiled with only \r rather than \n\r. If lines overwrite themselves, enable a switch on your terminal program which converts CRs to CR/LF.

### 2.3.2. POWER SUPPLY

Two power supplies are required for operation of FAME. One is supplied, the other must be locally obtained. The one supplied is a used IBM PC, 63 Watt power supply which is sufficient to power the MCU board and has the requisite +12, -12, and +5 Volt taps. The second power supply which is required is 9.6 to 12 Volts for powering the helicopter motor. A circuit diagram of one used at Drexel University is included in the appendix. A 9.6 Volt, 1000 mAh NICAD battery is provided to get you started, but will only supply enough current for 10-15 minutes of operation. These are the normal flight batteries. This battery should be recharged at the normal c/10 rate of 100 mA. Quick charging is possible if care is taken to not overcharge the batteries. Constant voltage charge is NOT an acceptable method for recharging NICAD batteries. Twelve Volt Gel-Cell batteries are recommended if a sufficiently robust power supply cannot be obtained. Conventional wet-cell lead acid batteries can be used if proper ventilation is maintained during recharging to prevent hydrogen buildup. Normal current draw for the motor is in excess of 10 Amperes.

The power for the servos is supplied through the electronic speed controller, so, in order for the servos to function under 68HC11 control, power must be supplied to the speed controller and it must be switched on. As long as the push-button is not pushed, power will not be supplied to the motor, although the green and red lights on the speed controller will change as it is still receiving commands. The +5 from the speed controller and the 68HC11EVB are not tied together. There is a common ground reference between the two so that the signals from the EVB can control the servos.

### **3. Operational Interface**

The basic communication principle employed between the users workstation and the MCU is that the MCU responds to commands passed to it from the workstation over an RS-232 bidirectional connection operating at 9600 baud. Commands include servo control data and position requests among others. These commands/requests are in the form of a serial byte string comprising a start character, a control character, one or more data bytes, a checksum, and a stop character. The message format must be exact or it is rejected. The user's workstation software should check for a response from the MCU within a short time to insure that has received the message and is working properly. The accompanying PC based software incorporates such checking.

#### **3.1. MC68HC11 Communications**

There are two serial communication ports on the M68HC11EVB. The one which is internal to the MCU is used for communications with the workstation and is under the direct control of the FAMEMAIN.C program. The other serial port is handled by an off-chip 8250 UART and is used to communicate to a terminal (usually a PC running a terminal emulation program such as Kermit or Procomm). In normal operation, the terminal does not need to be connected and is only necessary for using the BUFFALO monitor, downloading modified programs, or using special testing software.

Serial communications to/from the workstation are handled in the MCU through an interrupt driven Serial Communications Interface (SCI) routine. The complete message is stored character by character as it is received and the checksum and format verified before a semaphore is set indicating the reception of a complete message. When the foreground detects this message received semaphore, it enables other foreground and background functions to take place by setting or clearing other

semaphores. The dichotomy between foreground/background emphasizes the architectural uniqueness of the MCU in that many functions can be performed in hardware with interrupts indicating their completion. Extensive use is made of this feature so that TX/RX communications can be maintained in the background while interruptable foreground processes continue.

### 3.2. Workstation/MC68HC11 Message Formats

There are several messages which can be sent between the workstation and the MCU. The start character is ASCII "S" and the stop

character is ASCII "s". The checksum is the modulo 256 sum of all data except the start character, the checksum byte and the stop character. The position variables are all 16-bit integers and the most significant byte (MSB) must be put in `PostTXbuff[i]` and the least significant byte in `PostTXbuff[i+1]`. Data are not encoded as characters, but are the actual binary values which must be concatenated. The number in parenthesis is the position of the character or byte in the message string. The available messages are listed in Table III.

### 3.3. Workstation (PC) Communications

In order to verify proper software operation, a communications protocol interface is supplied which is PC based. If a PC is not available, then the C source can be recompiled for alternative machines. The program is **not** a control program, but rather the skeleton of a communications routine which would be included as **part of a neural network control implementation**. Of particular interest to PC users is the **interrupt service routine for serial communications**. MS-DOS does not use an ISR for serial communications and is therefore not suitable for MCU communications. This difficulty is circumvented by installing an ISR to handle serial communications. There appears to be incompatibilities among PC hardware and the software is not guaranteed to work on all PCs. It was

**Table II** Signal description for 6-pin Molex connector supplying power to stand.

| Pin Number | Description | Color Code        |
|------------|-------------|-------------------|
| 1          | Motor Gnd   | Thick Black (#12) |
| 2          | Motor +12V  | Thick Red (#12)   |
| 3          | 6811 Gnd    | Black             |
| 4          | 6811 +5V    | Brown             |
| 5          | 6811 -12V   | Red               |
| 6          | 6811 +12V   | Orange            |

**Table III** Workstation/MCU Message formats.

| ORIGINATOR  | MESSAGE                                                  | MESSAGE STRING                                                                                                                                    |
|-------------|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|

| Workstation | Request Potentiometer<br>Values (not yet<br>implemented) | Start Char(0), ____ (1), Stop Char(2)                                                                                                             |
| MCU         | Send Position Values                                     | Start Char(0), P(1), X(2-3), Y(4-5), Z(6-7),<br>Roll(8-9), Pitch(10-11), Yaw(12-13),<br>Checksum(14), Stop Char(15)                               |
| MCU         | Send Acknowledgement of<br>receipt of control values     | Start Ch. __, A(1), Stop Char(2)                                                                                                                  |
| MCU         | Send Potentiometer Values<br>(not yet implemented)       | Start Char(0), ____ (1), H-Pot(2-3), Az-Pot(4-5),<br>El-Pot(6-7), Roll Pot(8-9), Pitch Pot(10-11),<br>Yaw Pot(12-13), Checksum(14), Stop Char(15) |

developed using Borland C++ and ran successfully on an ATT-6300 (286) and an INTRA LT-386sx laptop (it did not run on a Zenith 386/16).

### 3.4. Coordinate Conversion

The measurements of the 6-DOF are not made in Cartesian space but rather in joint space. These angular measurements are converted by the MCU into an X, Y, Z, roll, pitch, and yaw format. This is done by applying the calibration values which are stored in nonvolatile RAM to the measurements and then computing the Cartesian coordinates through trigonometric conversions. The roll, pitch, and yaw do not require coordinate conversions since they are measured directly. A scale factor stored in nonvolatile RAM is still applied to convert the measured voltages into angles. Units for these measurements are centimeters for X, Y, and Z and degrees for Roll, Pitch, and Yaw. Scaled values are transmitted to maintain resolution. The current version of the software (1.0) scales all values by a factor of 100 before transmitting them back to the PC.

### 3.5. Servo Outputs

In normal radio controlled operation, servos expect to receive their 1.0 to 2.0 ms signal pulse once per 1600 sec. Although the interval does not have to be this long, they will malfunction with too short an interval. As there was not enough output compare to control all the servos, each output compare controls 1 pin PA and 1 pin PB.

Table IV Servo block connections.

| OUTPUT COMPARE<br>NUMBER | SERVO BLOCK<br>CONNECTOR<br>NUMBER | PORT NUMBER | MCU PIN<br>NUMBER | SERVOs<br>CONTROLLED |
|--------------------------|------------------------------------|-------------|-------------------|----------------------|
| OC3                      | 6                                  | PA5         | 29                | Collective           |
| OC3                      | 5                                  | PB2         | 40                | To Gyro              |
| OC4                      | 4                                  | PA4         | 30                | Rudder               |
| OC4                      | 3                                  | PB1         | 41                | Elevator             |
| OC5                      | 2                                  | PA3         | 31                | Aileron              |
| OC5                      | 1                                  | PB0         | 42                | Throttle             |
| IC1                      | 0                                  | PA2         | 32                | From Gyro            |

The servo connections are organized as shown in Table IV:

### 3.6 A/D Input Block

The six potentiometers which measure the angles of the six joints are connected to the MCU through a multi-connector block immediately behind the M68HC11EVB. As with the servo connections, the wires are numbered with the corresponding number on the block. Power is supplied to the A/D block from the  $V_{cc}$  and  $V_{ee}$  of the M68HC11EVB. The A/D channels and connector block pin assignments are as in the following table.

### 3.7. System Verification Software

A PC based program, FAMEPC.C, is provided which demonstrates the control capability available

**Table V** A/D converter signal/pin assignments.

| A/D CHANNEL | A/D REGISTER | PORT NUMBER | M68HC11EVB PIN NUMBER | A/D BLOCK PIN NUMBER | SIGNAL     |
|-------------|--------------|-------------|-----------------------|----------------------|------------|
| 1           | ADR1         | PE0         | 43                    | -                    | Buffalo    |
| 2           | ADR2         | PE1         | 45                    | 1                    | Roll (3Y)  |
| 3           | ADR3         | PE2         | 47                    | 3                    | Yaw (3Z)   |
| 4           | ADR4         | PE3         | 49                    | 5                    | Pitch (3X) |
| 5           | ADR1         | PE4         | 44                    | 0                    | Az(2Z)     |
| 6           | ADR2         | PE5         | 46                    | 2                    | El(2X)     |
| 7           | ADR3         | PE6         | 48                    | 4                    | H (1Z)     |
| 8           | ADR4         | PE7         | 50                    | 6                    | -          |

through the RS-232 interface to the MCU.

Servo position values can be typed in directly in milliseconds of control value (from 1.0 to 2.0 ms) or the individual servos increased or decreased by their smallest value through pushing the upper case value of the controlling letter or the lower case letter respectively. The controlling letters are shown in Table VI.

### 3.8. Calibration

In order to **eliminate** tedious alignment of potentiometers **at each joint**, it was decided to **align the joints electrically** rather than mechanically. That is, the exact position of the potentiometer is not important as long as it can be corrected prior to its use in the conversion Cartesian coordinate conversion. This is done by measuring the voltages produced at specified angles during a calibration program and computing a zero and scale factor. These factors are stored in nonvolatile RAM. As

**Table VI** PC keyboard controls.

| SERVO      | CONTROLLING<br>(UC INCREASES, LC D |
|------------|------------------------------------|
| Throttle   | T c                                |
| Tail Rotor | R o                                |
| Collective | C o                                |
| Elevator   | E o                                |
| Aileron    | A c                                |

long as the stand is not disassembled, there is no need to recalibrate since the correction values are stored in nonvolatile storage which is retained even if power is removed.

The calibration program, FAMECAL.C, must be downloaded into the M68HC11EVB and started using the Buffalo monitor. A terminal emulator must be connected through the port other than the one which is connected to the workstation. Communications are at 9600 baud, no parity, one stop bit. If power is removed from the evaluation board, the program will be lost since part of it is loaded into volatile RAM. This is not the case for FAMEMAIN since it all resides in non-volatile RAM.

### 3.9 DOF Range Limitation

There is a red colored round collar immediately below the platform which holds the helicopter. That ring is fixed in position with screws. The collar is there to limit the range of motion in the roll, pitch, and yaw axes during initial NN control program development. The total range of motion about these axes is great enough with the red collar removed that the tail rotor and boom can strike the stand and cause extensive damage to the helicopter. After some confidence is gained in the control algorithms and its implementation, the red collar can be lowered by removing the two screws and drilling and tapping new holes at a lower position. The tap size is 6-32.

An easier way to lower the collar is to compress the springs by tightening the bolts which hold the two red rings together. The best alternative which will allow complete range of motion and yet not require the removal of the platform/helicopter as detailed below is to remove the four bolts/springs which couple the two and then use shorter bolts/nuts to hold the two red rings together with no distance between them.

Complete removal of the collar requires that the helicopter and platform be removed from the supporting shaft. This could be done either of two ways. The recommended removal technique is to disconnect all of the wires from the helicopter/platform to the servo and A/D blocks as well as the motor power supply. Slowly rotate the helicopter/platform counter clockwise (CCW) when viewed from above until the allen head bolt which limits the range of motion of the yaw axis makes contact with the bracket at the bottom of the platform supporting shaft. Continue turning the platform with steady CCW pressure until the threaded portion of the shaft disengages from the inverted joystick on

the platform (the joystick measures roll and pitch angles). It will take several turns to remove the platform from the supporting shaft. The washers are required between the shaft and the joystick to compensate for the fact that the threads could not be machined completely to the flat face of the shaft and it is the flat face of the shaft which must mate with the flat surface of the joystick to produce true rotational motion. The number of washers determines the zero yaw position of the helicopter. Some washers must be present when reassembling the platform/shaft. Be sure to use Locktite on the threads when reassembling and do not overtighten as there is a chance of stripping the threads in the aluminum joystick (they are quite expensive) or shearing the threaded portion of the supporting shaft (which is custom made).

A less desirable alternative is to disconnect all wires as above and then unscrew the allen head cap screw which connects the supporting shaft to the yaw axis potentiometer at the bottom of the shaft. If the spring clip immediately above the allen head cap screw is then removed, the shaft should be able to be pulled upwards through the two roller bearings, effectively removing the shaft, platform, and the helicopter simultaneously. This method is not recommended as the alignment of the bearings is critical for smooth operation about the yaw axis and, more importantly, the yaw axis potentiometer must be recalibrated both electrically and mechanically. Electrical alignment is required so that the proper angle is measured by the A/D converter. Mechanical alignment is required to insure that the allen head cap screw limits the range of motion about the yaw axis so that the potentiometer is not destroyed. The potentiometer is not strong enough in rotation to stop the helicopter and a mechanical stop must be used.

There is a second purpose for the red collar. A close inspection will reveal that one of the screw/nut pairs through the springs is reversed which causes the nut to protrude slightly above the red ring. This is done so that the helicopter platform has something to push against while the rotor speeds up and before the tail rotor has reached an effective speed for controlling yaw. Once the helicopter is hovering, the platform does not make contact with the nut. The commercial speed controller which is supplied does not have a slow ramp up and tends to jerk the main rotor even with minimal control action. This too can cause the helicopter to yaw violently leading to the possibility of damage.

### 3.10 Connector Wiring

The standard connector for wiring signals is the "Dean's" connector. This is a three pin connector which we have used in the following standard.

One end of the connector is distinguished by a groove between two pints. Starting at this end, the signals on the connector are: Signal, +5 Volts, ground. This is true for the potentiometers used to measure the angles as well as the servos. It is possible to connect these connectors backwards in spite of the fact that there is a different spacing between the signal and +5V pin. The notches must line up.

On connecting the Dean's connectors to the servo and A/D block, note that the block has a white line which indicates the position of the groove in the connector.

**Table VII** Signal description for 4-pin Molex connector supplying power to MC68HC11EVB

| Pin | Signal    | Color  |
|-----|-----------|--------|
| 1   | Ground    | Black  |
| 2   | +5 Volts  | Brown  |
| 3   | -12 Volts | Red    |
| 4   | +12 Volts | Orange |

Exercise caution when wiring around the servo and A/D blocks which are epoxied to the stand behind the MC68HC11EVB as the pins which protrude from the blocks (next to the connectors which are plugged in) have +5 Volts and Ground on the lower two pins .

The system has been supplied with an 6-pin Molex connector through which power connections are made to the system from the external motor power supply and the PC power supply. The voltages on these pins are as listed in Table VII. Female pins are used on the power supply side and male pins used on the stand side.

A four pin **Molex** connector is used to connect power to the MC68HC11EVB. The voltages on these pins are as **listed in** Table VII.

## 4. Software Development

All of the MCU software was developed using a C cross-compiler/cross-assembler from INTROL

corporation. If further development by the user is desired this, or a similar cross-compiler/cross-assembler, needs to be purchased. All of the source code for both the PC and the MCU is available on disk as well as listed in the appendices. The emphasis was on C with only those portions of code requiring the fastest processing or unusual hardware control written in assembly language.

PC based software for the calibration program and sending/receiving of commands, requests, and messages was developed using Borland Turbo C++, although no ++ enhancements were used and the program was compiled with Turbo keywords on so that PC specific I/O routines could be used.

#### **4.1. Foreground/Background Software Design**

The implementation of the code is best understood with reference to a foreground/background approach. Interruptable processes are run in the foreground with their execution and behavior controlled by tokens which are either set in other processes or in the interrupt service routines. Some tokens are hardware flags which are read to determine their TRUE/FALSE value. For example, the serial communications interface (SCI) in the MCU is interrupt driven. Upon receipt of a character, the interrupt service routine (ISR) first checks to see if there are any errors (overrun or framing), then checks for start character and/or command character, stores data characters and then compares the locally generated checksum with the one transmitted. Only when all of these checks are complete in the background ISR is a semaphore set which tells the foreground process that a complete message has been received.

Hardware background processes are used extensively because they are readily available on the 6811 MCU. For example, the pulses sent to the servos are controlled through the use of the output compare (OC) registers in the MCU. These registers are loaded with a value. When the value in the OC register matches that of the internal free-running counter (TCNT), an interrupt is generated. Since there are only 5 OCs, three of them are used to drive two servos. The ISR for an OC determines which servos pulse width has passed and clears it to zero before reloading the OC register with a value that will tell it when to turn off the other servo which it controls. It must be emphasized that these OCs are hardware comparators which operate in the background and generate an interrupt when their value matches that of the free-running counter. After both pulses are cleared to a low value, the array of pulse widths is read to determine the duration of the low value and this is timed. After the low

value interrupt occurs, a new round of high pulses is programmed. The OCs are loaded from the arrays which store the values. It is the foreground process which, after detecting a message received semaphore, reads the command message and stores the data in the array of pulse width duration values. Since the actual PWs are generated in the background continually, the new pulse widths are output as soon as they arrive. Output pulses are generated sequentially, the automatic bit set feature of the OC was not used.

#### **4.2. M68HC11EVB Buffalo Monitor**

The Motorola supplied Buffalo is maintained intact in the evaluation board. Its limited repertoire is still usable for unassembling or modifying the executable code. On restart, the MCU fetches the address of the startup routine from locations \$FFFE/FFFF. As delivered in the 68HC11EVBU, this points to the Buffalo monitor. In order to start in either Buffalo or FAME, the user must set jumper J-4 to connect pins 2-3 rather than pins 1-2 for Buffalo. The Buffalo monitor reads this jumper to determine which mode of operation is desired. For users without a PC, this allows using FAME without always having to start up in the Buffalo monitor and then switch to FAME through the GO command.

#### **4.3. INTROL C Cross-Compiler/Cross-Assembler**

To one familiar with Borland C++, the INTROL cross-compiler is a bit difficult to use. The error messages are sometimes cryptic, and the linker command file (which controls the object module linking process) is difficult to set up. To minimize confusion about the method of locating the ISRs and their pointers during the linking process, the linker command file is listed in section 6.3, Appendix III.

### **5. System Support**

Questions concerning FAME can be directed by email to khintz@fame.gmu.edu. Very limited repair parts are available from GMU and the user is expected to become self-sufficient once delivery of FAME is made. To assist in that end, the next section lists suppliers of the various components. Dimensioned drawings of custom mechanical parts are available and included in the appendix.

Also available for 1 week loan are two VHS video tapes which are a basic introduction to model helicopter construction and flying. The two titles which we have from the "Milt Video Library" are "Model Helicopter Building and Flying Techniques", and "Advanced Helo Flight Course, Intermediate and Advanced Techniques." Don't rush out and buy them, but they are worth borrowing from us.

### **5.1. Spare Parts (suppliers)**

Ace R/C Inc.

116 W. 19th Street

P. O. Box 511

## **5.2. Acknowledgements**

Instrumental in the development of FAME have been Bertina Ho-Mock-Qai, a visiting research scholar, Elsa Lam, a senior Electrical Engineering Student, and Darrell Duane, a graduate research assistant in Electrical Engineering.

## 6. Appendices

### 6.1. Appendix I: MC68HC11 C Source Code

This code is included for reference only. It is a fully functional, correctly operating program but does not contain the latest updates. Please contact khintz@fame.gmu.edu for the most recent version of the code.
