ABSTRACT

German Army light helicopter transportation regiments operate 45 Bell UH-1D helicopters to support demanding missions throughout Europe. Maintenance period scheduling, major exercise and regular mission assignment decisions directly influence the readiness of the helicopter fleet. Currently, all planning is done manually, which is unstructured and time consuming. This thesis describes a decision support system designed to assist with maintenance planning and mission assignment. The yearly maintenance and event scheduling problem and the short term mission assignment tasks are formulated and solved as elastic mixed integer linear programs. Resulting yearly schedules and short term sortie plans are both generated in a fraction of the time previously required with solution quality superior to their manual counterparts.

EXECUTIVE SUMMARY

This thesis develops two optimization models and proposes an interface for a self sufficient personal computer based decision support system as an interactive instrument to construct reliable and completely organized helicopter usage and maintenance plans. The optimization models assist with yearly maintenance and event scheduling, and short term helicopter - mission assignments. Computational experience shows both yearly schedules and short term sortie plans are generated in a fraction of the time previously required with solution quality superior to their manual counterparts.

These results are for a German Army light helicopter transportation regiment operating 45 Bell UH-1D helicopters. For such regiments, maintenance period scheduling, major exercise, and regular mission assignment decisions directly influence the readiness of the helicopter fleet. The planning supervisor in the regiment's maintenance and repair battalion strives to keep high technical and operational standards while meeting all necessary inspections (16 different inspections during a 1200 flight hours cycle), satisfying all mission and exercise requirements, equitably using the helicopters, and smoothly operating the maintenance facilities. Done manually, these tasks are unstructured and time consuming.

The two optimization models provide valuable assistance to the planning supervisor. The yearly planning model assigns

helicopters to inspections and to exercises while observing monthly planned flight hours and operational guidelines (a desired level of flight hour reserve, a percentage range of operationally ready helicopters, an upper level of monthly flight hours per helicopter, and inspection capacities). The short term model assigns helicopters to missions while observing the technical status of each helicopter (remaining flight hours to next inspection, planned time of next inspection, availability) and fulfilling all mission requirements with respect to flight hours, and equipment.

Resulting yearly schedules and computed short term mission assignment plans are face-valid (*i.e.* judged implementable by expert opinion), superior to their manual counterparts (*i.e.* fewer planning conflicts) and generated in a small fraction of the time previously required.

Included in this study are the system's structure, the development and implementation of the two optimization models, computational results, the interface proposal, and explanations regarding the planning process and intended user.

I. INTRODUCTION

German Army light transport helicopter regiments operate 45 Bell UH-1D helicopters (see Figure 1) in support of a corps with three army divisions. A maintenance officer or "Leiter

Figure 1

Einsatz" (the author's assignment from 1989 to 1991) in the regiment's maintenance and repair battalion supervises the helicopter fleet maintenance planning and mission assignment. He strives to keep high technical and operational standards while:

- Meeting all necessary inspections,
- Satisfying all mission requirements,
- Fulfilling special events such as NATO exercises,
- Equitably using the helicopters,
- Smoothly operating all maintenance facilities.

This thesis derives and solves integer linear programs to assist with maintenance planning and mission assignment.

A. BELL UH-1D INSPECTION SYSTEM

The Bell UH-1D maintenance cycle (in its German version) consists of 1200 flight hours and contains 16 different inspections in two levels (C and D). The C-level (see Table 1) includes relatively easy maintenance and part replacement, the D-level (see Table 2) contains costly repair overhauls lasting three to five weeks. Each inspection takes place 75 flight hours after its predecessor in the following order:

C1, C2, C1, D1, C1, C2, C1, D2, C1, C2, C1, D1a, C1, C2, C1, D3.

C and D inspections are accomplished in disjoint facilities with different technical personnel. The C inspections, being relatively easy, can be performed without using fixed installations (e.g. during exercises).

TABLE 1

C-LEVEL (Maintenance)	
NAME	DURATION
C1	1 to 3 working days
C2	2 to 5 working days

TABLE 2

D-LEVEL (Repair)		
NAME	DURATION	FLIGHT HOUR
D1	3 weeks	300
D2	4 weeks	600
D1a	4 weeks	900
D3	5 weeks	1200

B. CURRENT PLANNING PROCESS

The maintenance officer in charge of the planning and mission assignment tasks has a staff of up to six soldiers experienced in the fields of aircraft repair and maintenance. Despite access to a personal computer (PC), maintenance and mission assignments are currently based on poorly documented manual procedures which rely on complicated charts and overview boards.

The planning process breaks into two related pieces, yearly and short term. The yearly maintenance and event schedule takes a three man team up to five weeks to produce. The final product contains the flight hours assigned to each helicopter each month, helicopters assigned C and D inspections each month, and helicopters assigned to fly

special events (e.g. operations of the Allied Mobile Force in northern Norway or in eastern Turkey, which require up to 12 helicopters to fly a total of more than 1000 hours). The short term plan provides individual helicopter mission assignments for up to one week. Time needed to develop the short term plan varies substantially depending on mission requirements and helicopter availability. A typical short term plan requires one man approximately two hours.

1. Yearly Maintenance and Event Schedule

Input to the yearly maintenance and event schedule includes:

- The total number of hours the helicopter fleet should fly,
- Special event requirements,
- Pilot Combat Training Programs (CTP, provide required monthly instructional flight hours),
- Operating data from past years on availability and reliability of the (aging) helicopter.

The yearly schedule has four primary operational guidelines:

- The flight hour reserve,
- The percentage of operationally ready helicopters,
- The upper level of monthly flight hours per helicopter,
- The maximum monthly C and D inspection capacities.

The flight hour reserve is each helicopter's available flight hours to the next D inspection, summed over all helicopters.

An ideal level of 6,750 hours (number of helicopters * 0.5 * hours between D inspections or $45 * 0.5 * 300 = 6,750$) has historically been a good planning factor. A level above 7,500 hours has endangered future equitable use of the maintenance facilities (i.e. a disproportional number of helicopters require imminent inspections), a level below 5,500 hours has endangered the capability of the regiment to fulfill all required missions.

The percentage of operationally ready helicopters measures the number of helicopters not in a D inspection and with remaining hours to the next D inspections greater than zero. A level between 70% and 90% is desired.

No more than 30 flight hours should be assigned to each helicopter each month, but violations are sometimes necessary (e.g. for events).

The normal output capacity for D inspections is three per month. If planned well ahead, an output of four per month is achievable, but reserve capacity for exception repairs is lost and an equally high output in the succeeding month is unlikely. The C-inspection level capacity is easier to manage. Output variations from one to six helicopters in one week are possible.

2. Short Term Helicopter - Mission Assignments

The short term planning process attempts to pick the correct helicopter for each mission while observing:

- The number of flight hours each helicopter has until the next inspection
- The planned time and importance of the next inspection,
- The mission's flight hour requirement,
- The current equipment status and the mission's equipment requirement,
- The possible multiple use of the helicopter for non-simultaneous missions.

This daily task requires experience and talent. Unfortunately, an organized method of meeting the listed criteria is often blocked by time considerations.

C. OBJECTIVES OF THIS THESIS

The objective is to develop underlining algorithms and propose an interface for a self sufficient PC based decision support system as an interactive instrument to reach reliable and completely organized helicopter usage and maintenance plans.

The approach undertaken in this thesis is practical and centered around two optimization models.

Chapter II addresses similar concepts in the existing literature. Chapter III contains the developed algorithms, the proposed interface and both user and planning session descriptions for the decision support system. Chapter IV

contains the computational performance of the developed models and Chapter V provides conclusions.

II. RELATED RESEARCH

A literature search did not reveal a model with the capabilities needed by the German Army Aviation maintenance officer. His tasks are very specific, dependent on the German version of the Bell UH-1D preventive maintenance system and the local maintenance resources. The combination of a yearly plan with a short term mission assignment system, the necessity of using this system independently and the exclusion of manpower, budget and logistic issues make the proposed model unique.

However, decision support and expert systems for aviation maintenance activities have been studied for other aircraft and organizations. Hackett and Pennartz (1982) provide the basis of a decision support system for the maintenance aircraft scheduling process of an United States (US) Air Force B-52 wing. They start with the principle that computerization without proper management does not improve overall performance. They therefore first establish maintenance responsibilities and management procedures for an operational cycle that considers everything from the yearly flight program to the daily scheduling update operations. They characterize maintenance scheduling as a complex process with a high degree of uncertainty, strict requirements, binding constraints and

insufficient guidance. In their view, successful usage of optimization models in the different planning stages depends on appropriately reducing the complexity of the problem with simplifying and structuring techniques. They do not, however, develop optimization models or algorithms. Key aspects of a decision support system are reported as:

- Communicability with the user,
- Robustness even for extreme cases,
- Ease of Control.

Shenolikar (1983) describes a decision support system for automatic test equipment systems operations management, which is closely related to aircraft maintenance affairs. Optimization models are again addressed, but not formulated. The key elements of a generic decision support system are developed as follows:

- Knowledge base (with proposed algorithms and solution models),
- Data directory and data base,
- Report generator,
- Communications (interface) manager.

A series of theses (see Christensen and Pasadilla, 1991) advised by Professor Martin J. McCaffrey (Department of Administrative Science, United States Naval Postgraduate School) develops a Naval Aviation Maintenance Organizational

Activity Strategic Information System (OASIS) and an Expert System Advisor for Aircraft Maintenance Scheduling (ESAAMS). These complex systems address flight and maintenance activities, but include also human resources (manpower management, training and qualification), monetary management (budget considerations and accounting) and inventory structures for logistical support. These programs deal with the combined use of present information systems of the US Naval Air Systems Command and design applicable knowledge bases, databases and graphical interfaces. Again, these systems only propose optimization models and algorithm as future work.

In addition to these expert systems for planning aircraft related maintenance and use, the literature search did reveal an optimization model concerned with helicopters and one dealing with military aircraft sortie planning. The "Phoenix" model (Brown, Clemence, Teufert and Wood, 1991) includes procurement and retirement schedules for the US Army's helicopter fleet, handling 16 different helicopter types over 25 years. The mission assignment problem is described by Wallace (1992), who develops sortie optimization tools for the US Air Force.

The search for related maintenance planning systems in use by commercial airlines was not successful. Commercial airlines are concerned with a different set of constraints (costs) and resources (see Talluri and Gopalan, 1993).

III. CONCEPT OF THE DECISION SUPPORT SYSTEM

A. STRUCTURE AND OVERVIEW

The system organization (see Figure 2) resembles the underlying manual planning process and consists of two almost independent parts:

- The yearly maintenance and event planning system,
- The short term planning system for mission assignment covering up to one week.

Figure 2

Each subsystem has the ability to respond to user preferences and demands. The scheduled inspection periods are input to the short term planning system which forms a connection between the two parts. There is no direct feedback out of the short term planning process into the yearly system, because a continuous change of the yearly plan destroys the underlying planning policy. There are good possibilities to get a yearly plan "back on track" when unforeseen trouble strikes. The experienced user has to decide, when a complete renewal of the yearly plan is necessary. Every subsystem result can and should be adapted manually. Results are proposals, providing feasible starting points for further planning and adapting to reality. All the important existing constraints are present in the different models, but elastic violations are possible (like real decision making) by paying adequate penalties.

B. THE YEARLY PLANNING SYSTEM

1. Basic Specifications

The yearly planning system forms the basis for all maintenance scheduling and mission assignment. It recognizes initial conditions and requirements from the planning data and implements the planning policy. The essence of this subsystem is an integer linear program. The necessary input can be expressed as:

- Planned flight hours per month for the fleet,

- Special event requirements (time, flight hours, number of helicopters, maintenance possibilities),
- D-level maintenance capacity,
- Status of each helicopter (remaining flight hours to next D inspection).

The final output includes :

- Recommended flight hours for each helicopter each month,
- Recommended D inspection decision for each helicopter each month,
- Helicopter assignment to special events,
- Monthly statistics with respect to flight hour supply and helicopter availability.

A Pascal program transforms the yearly solution (containing monthly decisions) into a solution containing weekly results and C inspection decisions. A description of this program follows the yearly planning model.

2. The Yearly Planning Model

The model specifications in a basic format can be described as follows:

■ INDICES:

- t month (e.g. 1,2,...,12),
- h helicopter identification (e.g. 1,2,...,45),
- e event (e.g. 1,2,...,E).

■ DATA:

- PLHRS_t planned flight hours for month t,
- EVENTHRS_e flight hours required for each helicopter participating in event e,

EVENTNMB_e number of helicopters required for event
 e,
 DMAX maximum number of D inspections per month,
 PRODHRS additional flight hours (e.g. 300)
 obtained per inspection,
 OPTSUP desired flight hour supply (e.g. 6,750),
 MININSP_t minimum number of inspections in month t,
 MAXHRS maximum regular monthly flight hours for
 each helicopter (e.g. 30).

■ VARIABLES:

BINARY VARIABLES

$Z_{h,e}$ one if helicopter h is assigned to event e,
 $Y_{h,t}$ one if helicopter h is assigned a D inspection
 in month t.

POSITIVE VARIABLES

$X_{h,t}$ flight hours assigned to helicopter h below
 MAXHRS in month t,
 $XE_{h,t}$ flight hours assigned to helicopter h in month
 t exceeding MAXHRS or in addition to an
 inspection or event assignment,
 $REMHS_{h,t}$ flight hours until next D inspection for
 helicopter h at end of month t,

■ MODEL:

- * Minimize the sum of all weighted elastic penalties and $XE_{h,t}$ hours.

* subject to the constraints:

$$(1) \quad \sum_{h=1}^{45} [X_{h,t} + XE_{h,t} + \sum_{e=1}^E EVENTHRS_e * Z_{h,e}] \doteq PLHRS_t \quad t=1..12$$

$$(2) \quad \sum_{h=1}^{45} Y_{h,t} < \doteq DMAX \quad t=1..12$$

$$(3) \quad \sum_{h=1}^{45} Y_{h,t} \geq MININSP_t \quad t=1..12$$

$$(4) \quad REMHRS_{h,t} = REMHRS_{h,t-1} + PRODHRS * Y_{h,t} - X_{h,t} - XE_{h,t} - \sum_{e=1}^E EVENTHRS_e * Z_{h,e} \\ h=1..45, t=1..12$$

$$(5) \quad \sum_{h=1}^{45} REMHRS_{h,t} > \doteq OPTSUP \quad t=1..12$$

$$(6) \quad \sum_{t=1}^{12} [X_{h,t} + XE_{h,t} + \sum_{e=1}^E EVENTHRS_e * Z_{h,e}] \doteq (\sum_{t=1}^{12} PLHRS_t) / 45 \\ h=1..45$$

$$(7) \quad \sum_{h=1}^{45} Z_{h,e} = \text{EVENTNMB}_e \quad e=1..E$$

$$(8) \quad Z_{h,e} + Y_{h,t} + (X_{h,t} / \text{MAXHRS}) \leq 1 \quad h=1..45, e=1..E, t=1..12$$

■ REMARKS:

- The $\dot{=}, <\dot{=}, >\dot{=}$ signify elastic constraints.
- $\text{REMHS}_{h,0}$ provide the initial status of each helicopter.

■ DESCRIPTION OF THE CONSTRAINTS:

- (1) Meet planned flight hours each month or incur an elastic penalty.
- (2) Comply with the maintenance capacity or incur an elastic penalty.
- (3) Perform a minimum number of inspections each month.
- (4) Calculate remaining hours until the next inspection for each helicopter at end of each month.
- (5) Provide the desired flight hour supply or incur an elastic penalty.
- (6) Provide equitable use of the helicopter fleet or incur an elastic penalty.
- (7) Enforce number of required helicopters for each event.

- (8) Allow each helicopter to participate only in a special event, be inspected, or be assigned regular flight hours $X_{h,t}$ without penalties each month. Assignment of flight hours $XE_{h,t}$ despite an event or inspection is possible, but incurs the penalty associated with the variable $XE_{h,t}$.

C. TRANSFORMATION OF OPTIMIZATION RESULTS

A PASCAL program named "MOSCH" (Monthly SChedule) transforms the model solution into an editable form (see Appendix C). The objective is to translate the monthly decision variables into weekly results. Instead of operating with a general maintenance duration time for the D inspections of one month, the more realistic values for the respective D1, D2, D1a and D3 overhauls are utilized. The three required C inspections between every two D inspections are also added (recall the relative ease of planning these inspections). The basic approach can be described as follows:

- Process each helicopter ordered by initial flight hours until next D inspection.
- For each planned D-level inspection, schedule the inspection as soon as possible starting two weeks prior to the beginning of its planned inspection month. Ensure no planned hours or event conflict exists.
- If the starting week is feasible, check inspection workload and choose next available week with acceptable workload level.
- Schedule the inspection over its actual duration and check again for scheduling conflicts.
- Schedule all intermediate C inspections based on remaining hours to the next inspection for each helicopter.

- Note C inspection requirements during events.
- Print the schedule, a graphical overview and all required statistics.

D. THE SHORT TERM PLANNING SYSTEM

1. Basic Specification

The short term planning system assigns helicopters to missions while observing requirements of the yearly plan. It is proposed as an interactive program with a graphical user interface and an optimization model to perform mission assignment. Additional characterizations of the complete short term planning system are given later in this chapter.

The following addresses the optimization model, which can be used independently from the proposed system. Necessary input requirements for this mission assignment model are:

- Status of each helicopter with respect to availability, equipment, flight hours and inspection plan,
- Mission requirements with respect to flight hours and equipment.

The output includes an assignment proposal for each mission. Some sorties require a spare or backup helicopter to ensure mission success. The optimization model also decides the assignment of spare helicopters.

2. The Short Term Helicopter - Mission Assignment Model

This model chooses the best helicopter and (if required) spare helicopter for each mission. It takes the following helicopter properties into account:

- A user preference for mission assignment,
- The relative importance of the next inspection, expressed in weeks required for the completion,
- The time gap until the next planned inspection,
- The flight hours remaining until the next inspection,
- The current equipment condition,
- Restrictions for night or instrument flights,
- The overall availability during the planning time frame (no ongoing mission, event assignment or inspection).

Mission requirements are:

- Equipment,
- Flight hours,
- Backup demand,
- Time window,
- Night or instrument flight capability.

The equipment requirement is one of the following:

- 11 seats,
- 5 seats,
- 400 kg exercise load,
- Internal tank left,
- Internal tank right,
- Winch.

The number of items between any two equipment types on the above list (noncircular) represents the relative difficulty or time needed to change between the two equipment types. Therefore, a change between 400 kg exercise load and 5 seats is relative easy to do in comparison to a change between 11

seats and a winch. This approach is chosen, because data for a more realistic change-over matrix is currently not available.

A mission - helicopter assignment is only feasible, if the helicopter is available (expressed in a 0-1 availability subset), the helicopter is not assigned to a simultaneous mission, and mission requirements don't collide with flight restrictions of the helicopter. The mission requirements fall into one of the following codes:

- 0 = no operation limitations,
- 1 = helicopter restricted to Combat Training Flights (CTP) because of insufficient technical standard (e.g. non critical vibrations),
- 2 = helicopter restricted to Visual Flight Rules (VFR) missions because of absence of Instrumental Flight Rules (IFR) equipment,
- 3 = helicopter restricted to daylight flights only, because of absence of night sight equipment.

The model structure can be described as follows:

■ INDICES:

- h helicopter identification (e.g. 1,2,...,45),
- m mission identification (e.g. 1,2,...,M),
- i simultaneous mission group (e.g. 1,2,...,I).

■ DATA:

- Reminsp_h remaining hours to the next inspection for each helicopter h,
- Length_m flight hours for mission m,

$Cost_{h,m}$ penalty for assigning helicopter h to mission m ,

$Spare$ subset of all missions which require a spare helicopter,

$Overlap_i$ set of all missions in group i .

■ VARIABLES:

$FM_{h,m}$ binary assignment decision for helicopter h and mission m ,

$FS_{h,m}$ binary assignment decision for helicopter h used as a spare for mission m .

■ MODEL:

* minimize

$$\sum_{h=1}^{45} \sum_{m=1}^M Cost_{h,m} * (FM_{h,m} + FS_{h,m})$$

* subject to the constraints

$$(1) \quad \sum_{h=1}^{45} FM_{h,m} = 1 \quad m=1..M$$

$$(2) \quad \sum_{h=1}^{45} FS_{h,m} = 1 \quad m=1..M \text{ s.t. } m \in Spare$$

$$(3) \quad \sum_{m=1}^M [Length_m * (FM_{h,m} + FS_{h,m})] \leq Reminsp_h \quad h=1..45$$

$$(4) \quad \sum_{m \in Overlap_i} [FM_{h,m} + FS_{h,m}] \leq 1 \quad h=1..45, i=1..I$$

$$(5) \quad \sum_{m=1}^M FM_{h,m} \leq 1 \quad h=1..45$$

■ DESCRIPTION OF THE CONSTRAINTS:

- (1) Assign exactly one helicopter to mission m.
- (2) Assign a spare helicopter to mission m if required.
- (3) Each helicopter's flight hour use can not exceed its remaining hours until inspection.
- (4) A helicopter can not be assigned to more than one mission being conducted at the same time.
- (5) Assign each helicopter to at most one mission or incur an elastic penalty.

The variable $Costuse_{h,m}$ is a combination of weighted penalties for not choosing a helicopter with:

- the highest priority score,
- the most expensive following inspection (expressed in required completion time),

- the least expensive equipment changeover (expressed in equipment code differences),
- the smallest time gap to the following inspection.

Included is also a penalty for selecting a helicopter previously assigned a mission during the model's time frame.

A reformulation of the short term helicopter - mission assignment problem as a network flow model is possible. However, due to the success of the model described above (see computational results in Chapter IV) and the potential size of the network structure, this approach is not further investigated.

E. USER DESCRIPTION, PLANNING SESSIONS AND INTERFACE DESIGN

To fully understand the role of the two optimization models, it is necessary to present the context of the appropriate planning environment including a description of the users. The yearly model is primarily employed once a year by a well educated user and therefore can be used as demonstrated in chapter IV without an additional interface. The applicability of the short term model to assist with mission assignment is also demonstrated in chapter IV. Unfortunately, the intended user for the short term model lacks substantial familiarity with a personal computer. Therefore this section proposes a user interface for the short term model to assist with complex input and data manipulation needs.

1. Yearly Planning System

a. User Description

The yearly planning system user should have the following training, experience and educational requirements:

- Complete familiarity with the overall planning process,
- Computer skills including input/output problems and handling of textfiles,
- Basic skills in linear programming and familiarity with applicable software packages.

The use of the system by the maintenance officer in charge (usually with a master's degree in air and space technology or mechanical engineering) is recommended, but delegation to a computer experienced subordinate is possible. Every maintenance and repair battalion also has a "S6-Offizier", who is responsible for data processing and the computer facilities.

b. Description of a Planning Session

After preparing and screening the planning data (event information, the planned monthly flight hours, the maintenance facility capacities and the initial status of each helicopter), a textfile is filled with the required data in a simple coded form. Preferences and prefixed maintenance periods can be included. It is helpful to transform the achieved optimization model's solution into the more organized weekly schedule (now with C inspection recommendations included) for further analysis, using a transformation program

as described above. Statistics and a graphical overview can be prepared for command reviews. The overall time frame for a planning session as described depends on the familiarity with the system, the solver, the capacity of the personal computer and the difficulty of the plan. Based on computational results (see Chapter IV), approximately two working days should be sufficient for multiple iterations of data input, computer runs, solution review, and manual modification of the schedule.

2. Short Term Planning System

In addition to the mission assignment optimization model as described above, the proposed system (see Figure 3) contains graphical interfaces including an update task screen for helicopter status changes, a report section that includes the maintenance status for each helicopter, and a screen for generating the updated short term maintenance plan.

a. Interface Design

Interface proposals for each screen can be found in Appendix E. These interfaces need a not yet developed communications manager for screen control and initiating computational intermediate steps in the knowledge base, using the database information.

b. User Description

The recommended user for this part of the planning system is one of the two senior NCO's in the technical command

Figure 3

center. These are usually experienced soldiers with education as aircraft technicians and training in maintenance planning operations. Their computer skills can be basic. A practical briefing of a few days duration should be sufficient to enable this group of users to operate the subsystem. Expertise will be developed quickly during daily employment. The system design should include safety features against wrong input and confirmation procedures to prevent unintentional utilization. A simple interface structure, easy accessible, controllable and with convenient operation possibilities will ensure proper use of the system.

c. Description of a Planning Session

(1) *Update Process.* Every time the technical command center gets a vocal (telephone) or written report of helicopter status changes, an update screen allows the revision for the selected helicopter. These changes include:

- Failure of an operationally ready helicopter,
- Category of the failure,
- Estimated completion times for repairs or maintenance measures,
- Flight hour consumption,
- Equipment change overs,
- Special operation limitations,
- Renewed availability (mission or maintenance measurement completion).

The helicopter in question, identified by number, will be selected and a menu of instances appears. Each instance can be selected and changed within a range of offered possibilities. The confirmation of the changes concludes the update operation. An immediate report generation should be included.

(2) *Mission Assignment Process.* After determining the time frame for the missions in question (from one day to a week), a table asks for the mission requirements separated by a mission identification number. Simultaneous missions are marked with a common group index. Other needed data include flight hour requirements, estimated start and landing times,

description of the mission (combat training program or mission order number), spare helicopter requirement, equipment requirement and flight restrictions. The short term optimization model gives an assignment proposal for each mission and spare requirement. After reviewing the result, the user can accept the optimization proposal (in part or whole), rerun the optimization model, or manually edit the selection. The process finishes with a printed result (on screen or hardcopy) of the sortie plan.

(3) *Reports and Statistics.* A combined status report for a particular helicopter or the whole fleet can be selected at any time. This feature helps the supervisor in his control functions and generates required summaries for the next higher command levels. The statistics include:

- Percentage of available helicopters,
- Percentage of helicopters on mission,
- Percentage of helicopters in unplanned maintenance,
- Percentage of helicopters in planned maintenance,
- Flight hour reserve,
- Flight hour consumption so far for month and year,
- Available flight hours for rest of month and year.

Simple selection of the offered choices should be sufficient for generating the report and the statistics.

(4) *Short Term Maintenance Plan.* This special screen enables the user to issue his orders to the maintenance and repair level facilities. An updated extract of the yearly maintenance schedule is generated by selecting helicopters out of a candidate list, which includes helicopters already scheduled for inspection and those that will soon need inspection. The screen allows for comparison between the yearly plan and the updated short term version.

IV. COMPUTATIONAL EXPERIENCE

A. THE YEARLY MODEL

Two data sets (1989 and 1991) taken from the Army Aviation Regiment 30 in Niederstetten Air Base (Germany) show the applicability of the yearly model. The 1989 data (see Table 3) requires only two major events and is representative of a modestly difficult planning year. The 1991 data (see Table 4) pictures a difficult planning year consisting of four demanding events and a nonuniform yearly flight hour program. Unfortunately, the initial status of each helicopter (hours remaining until the next inspection and inspection type) is not known for either data set. Realistic estimates are based on the fleet's flight hour reserve, the percentage of operationally ready helicopters, and the author's personal experience. All computational results are obtained using an IBM compatible 486/33 Personal Computer. The model is generated using GAMS (Brooke, Kendrick and Meeraus, 1992) and solved using ZOOM (Brooke, Kendrick and Meeraus, 1992), XA (1993) and OSL (1991).

The GAMS code, which implements the yearly model can be found in Appendix A. The model reports approximately:

- 1,200 constraints in 10 blocks,
- 2,600 variables in 18 blocks (600 discrete and 2,000 continuous variables),

- 9,000 non zero elements.

Attempts to solve realistic instances of the yearly model optimally result in significant computational effort. Heuristic solution procedures were therefore investigated and found to provide quality solutions using substantially reduced

computation time. Two heuristic procedures are used, "LP-Rounding" and "Cascade". Both solution procedures rely on the relaxed integer solution being a valid information transfer tool for the pure integer task.

- LP-Rounding: After solving the linear programming relaxation, binary variables with values near zero or one are rounded respectively down or up to the nearest integer value and fixed. This process can be repeated indefinitely, but

for this application two iterations diminish the number of decision variables sufficiently to allow for a successful solve of the reduced mixed integer program.

- Cascade: A number of possible implementations exist for this heuristic technique. For the test problems considered, solving twelve (one for each month) linear integer programs works best. The first of these twelve problems relaxes the integer restriction for variables associated with months two to twelve. After solving, a new problem is generated with month one's variables set equal to the values obtained in the previous relaxation, month two's variables constrained to be integer, and months three to twelve variables relaxed. This process repeats until the binary variables for all twelve months have been restricted to be integer.

Independent of the heuristic solution procedure, several parameter settings are especially important (see Appendix A for a complete list). After several test runs using various parameter values, best results are achieved for:

- An upper bound on $XE_{h,t}$ (flight hours assigned to helicopter h exceeding regular usage in month t) of 30,

- A penalty value of 0.1 for $XE_{h,t}$,
- A penalty value of 0.01 for the elastic variables of constraint (6), which provide for the equitable use of the helicopter fleet.

More important than the actual value is the relative magnitude of a penalty with respect to the other penalties. Specifically, inequable use of the helicopter fleet is viewed as an order of magnitude less important than excessive use of an individual helicopter (ratio 1/10).

Solutions from the different solvers (ZOOM, XA, OSL) and the two solution methods for the 1991 data set can be compared in Appendix B. ZOOM achieves its lowest costs schedules using a specified branching order based on the natural hierarchy of the time dependent discrete variables. The solvers XA and OSL are applied with the default branch and bound schemes.

The quality of the solutions does not depend on the solver or the heuristic, but ZOOM requires substantially more time than XA or OSL, and the Cascade procedure requires slightly more time than the LP-Rounding method. All achieved solutions exceed the initial relative optimality tolerance values (OPTCR) of 0.10 or 0.15 (guaranteeing a solution within 10% or 15% of optimal respectively). These tolerances apply to each individual program run and can therefore not serve as computation stopping conditions for the final solution. The solutions presented in Appendix B have objective function values between 11% and 36% of optimal (using an initial cost value of 100). However, the resulting schedules are face-

valid (i.e. judged implementable by expert opinion) and considered superior to manually created plans.

Table 5 and 6 compare the manual and optimization model's yearly schedule for the two data sets. Without any additional manual editing, the selected system schedule for 1991 meets all requirements (percentage of operationally ready helicopters and flight hour reserve are in the desired ranges) and violates the realistic 30 hour planning goal and the planned hour per month constraints less than the manual solution (fewer planning conflicts). The computed schedule for the data set of 1989 shows similar advantages. The planned hours per month are now met exactly. Production time for both system schedules (including time needed for manual adjustment work) constitutes only a small proportion (approximately 1/12) of the usual manual completion time.

B. THE SHORT TERM HELICOPTER - MISSION ASSIGNMENT MODEL

The short term model is tested using data based on past experience in mission assignment. A sample test problem (including solution) can be found in Tables 7A and 7B. This 20 mission example represents a normal one day assignment task. Initial input data is listed in Appendix D and XA is the solver. The model is also tested successfully with a highly complex 40 mission example. This case has demand for 34 missions with 18 spare requirements and for an unplanned exercise requesting six helicopters (five with 45 required flight hours each and one with 22 required flight hours).

The model handles the test cases smoothly when using an IBM compatible 486/33 Personal Computer. It produces solutions within one to three minutes. All achieved test solutions have objective values within five percent of optimality.

The GAMS code implementing the short term model can be found in Appendix D. The default branch and bound scheme for the XA solver is used.

A comparison of manual and computed assignments is difficult and not appropriate when acknowledging the very practical purpose of the system. A program of several months in an actual environment should be employed to evaluate the utility of the model. Tests with realistic mission sets however show consistent and appropriate helicopter selections, which pass the "common sense" test. Acknowledged advantages

of system solutions are the absence of conflicting assignments caused by user error (given correct input) and the substantially reduced development time.

V. CONCLUSION

This thesis develops two optimization models and proposes an interface for a self sufficient PC based decision support system as an interactive instrument to construct reliable and completely organized helicopter usage and maintenance plans.

The yearly maintenance and event planning model produces face-valid schedules in substantially less time than current manual techniques. The proposed procedure is structured, outcomes can be stored for reports, command reviews, and as a base for future planning.

Using the proposed interface to enhance data manipulation tasks, the short term planning model for mission assignment is able to produce daily to weekly sortie plans in minutes and free of user error.

Using integer linear programming as a foundation for a computer based maintenance scheduling and mission assignment system can substantially reduce the workload and improve the quality of this complex planning process.

APPENDIX A IMPLEMENTATION OF YEARLY PLANNING SYSTEM

A. LP-ROUNDING METHOD

\$TITLE Helicopter Maintenance Scheduling
\$STITLE A.Sgaslik Thesis

- * Computes a yearly schedule for 45 helicopters with respect
- * to flight hour distribution, D inspections and events.
- * The following program characteristics influence solutions drastically
- * and need special attention:
- * • The relative termination tolerance OPTCR, which means that GAMS
- * will stop and report on the first solution found whose objective
- * value is within the specified tolerance of the best possible solution.
- * • The scalar DEVWEIGHT, which sets a penalty for no equitable use of the
- * helicopter fleet,
- * • The scalar EXPLWEIGHT, which sets a penalty for planning above the
- * monthly flight hour guideline for each helicopter,
- * • The restriction set of possible helicopters for event decisions R(T),
- * • The upper limits for flight hours for each helicopter and month X.UP
- * and XE.UP,
- * • The allowed percentage ranges for violating constraints (no penalty
- * violations).
