REAL-TIME DATA COLLECTION PROGRAMS AND SOURCE CODE
FOR A COMMERCIAL PASSIVE FTIR REMOTE SENSOR

1. INTRODUCTION

Passive Fourier Transform Infrared (FTIR) remote infrared (IR) sensing is a method of increasing popularity for the detection and identification of gaseous pollutants. Low-cost, commercial FTIR remote sensors are available that can detect the spectral absorptions or emissions of a chemical vapor cloud, using an ambient temperature thermal background. Current data analysis computer programs require the collection of an ambient background reference spectrum for subtraction. Many conditions exist in the detection of ambient vapor clouds in which it is not possible to obtain an accurate passive open-path background emission spectrum. These conditions include the use of a passive FTIR sensor in a fence-line or an open-path smoke stack monitoring application.

A typical fence-line monitoring application is shown in Figure 1. This application detection limit is governed by four basic parameters, which are as follows:

- the contrasting temperature between the background and the vapor cloud
- the cloud path length
- the cloud concentration
- the atmospheric attenuation of the IR energy

In addition, the spectral features of a chemical vapor cloud can be seen as either emission or absorption depending on the relative temperature of the cloud relative to that temperature of the ambient background. Because of the large number of atmospheric and instrumental variables, a passive IR spectrum can be so complicated that the identification of a particular vapor species can be easily missed. Automated real-time pattern recognition software can assist the operator in discriminating between the complicated background spectra and the spectral features of a vapor cloud.

Recently, a generic series of signal processing techniques has been developed to analyze passive remote sensing interferograms.¹⁻⁵ These methods use a digital filter combined with pattern recognition that can discriminate a particular chemical species versus all other interferents and spectral background features. A digital filter that is used is called a "matrix" filter. This filter is somewhat analogous to the background reference subtraction in that it removes the unwanted spectral background features before application of a pattern recognition procedure.

Figure 1. Operation of a Passive Infrared Remote Sensor

Real-time implementations of digital filter and pattern recognition interferograms are a necessity for passive-remote sensing measurements. Open-path measurements can be enhanced by the ability to notify an operator of the presence of a particular chemical vapor. A feedback mechanism provided by real-time software assists the operator in identifying spectral contributions from a vapor cloud before the conclusion of a particular experiment. The real-time data collection and analysis software enables the operator to make adjustments or modifications to the experimental design to improve data collection results from a field trial.

This study describes the computer software implementation of a real-time detection algorithm on a personal computer (PC) that has been integrated into a commercial interferometer hardware package. Data collection programs are described that enables the user to collect interferograms for later analysis. The data collection and analysis program names are listed in Table 1.

Table 1. Overview of Program Names

Name	Program Discussion
midcol	collects data to disk from the midac unit
replay	replays and displays collected risk data
mtrx	collects data from the midac and runs the matrix filter and pattern recognition program
mtrxd	reads data from disk and runs the matrix filter and pattern recognition program
matgraph	display the result file processed by programs mtrx and mtrxd
convintf	converts interferogram files created by the program midcol to a format that can be read by SPECTRACALC

2. EXPERIMENTAL PROCEDURES

Data collection and real-time data analysis software was developed for a commercial interferometer manufactured by Midac Corporation (Irvine, CA). This small, low-cost FTIR remote sensor can be configured as a passive, single-ended, or bi-static active system. The system can be used in an active mode that includes a parabolic mirror and an IR source. Active source configurations require the addition of a telescope allowing the field-of-view of the interferometer to be fully filled by the source for long path length applications. The passive arrangement (Figure 2) used for data collected for this study can be used either with or without a telescope. A telescope is not needed if the target chemical vapor cloud is sufficient to fill the field-of-view of the interferometer.

Figure 2. Data Collection Program Flow Chart

The Midac spectrometer consisted of a Michelson linear drive interferometer that was specifically optimized for the 8 to 12 μm wavelength atmospheric window. The interferometer had an optically coated nonhygroscopic front window with an optical diameter of 1.75 in. The interferometer beamsplitter was constructed of zinc selenide (ZnSe) and had a tolerance of better than 1% deviation from the 50% transmission optical requirement between the wavelength region of 7 and 14 μm . The IR energy exiting the interferometer was converged onto a 1 by 1 mm MCT detector element by a gold coated off-axis parabolic mirror. The detector element was mounted in a dewar and cooled with liquid nitrogen.

Analog data was amplified by a low-noise pre-amplifier and a low-noise, high-gain post amplifier. The analog signal was passed to a 16-bit analog-to-digital converter for digitization. The digitization rate of the analog-to-digital converter was controlled by a reference He-Ne laser and detector arrangement that included two visible detectors that also monitors the direction of mirror travel.

The interferometer hardware had the capability of scanning interferograms as short as 512 points or as large as 16 K points. In addition, the servo scanning hardware had the capability of sampling every He-Ne laser zero crossing or sampling as few as only every eighth laser zero crossing. The hardware servo sampling flexibility allows one to select an optimal sampling rate and resolution for a given open-path experiment. The software that was developed had the capability of collecting data at all of the sampling rates and resolutions that the interferometer hardware allowed.

3. DATA COLLECTION PROGRAM DESCRIPTION

Data collection software was completed in "C" language to allow for the storage and display of interferograms obtained from the Midac spectrometer. Version 3 of the software allows collection of interferograms at various resolutions and sampling rates for a display of the Fourier transformed spectrum. Two data collection programs allow for the data collection to disk and also the capability to display interferograms at a later time.

The interferometer data collection program (midcolv) enables the user to store up to 3000 sequentially collected interferograms into a single disk file. This collection program has the ability to Fourier transform the interferogram, background subtract a reference spectrum, or compute a calibrated blackbody reference spectrum in real-time to yield a corrected difference emission profile. Conversion from any one data display type to another is achieved by using single key strokes. A single keyboard control function is useful for outdoor remote sensing field applications where the use of a mouse or window display menus becomes difficult to manipulate. A flow chart of the data collection program is shown in Figure 2.

The data collection program has eight screen display options that are enabled with the use of function keys F1 through F8. Function key F1 is defaulted to display the first 400 points of a collected interferogram. The

interferogram screen display can be expanded or contracted to allow for more or less points to be displayed. The expansion and contraction functions are enabled by the use of four functions keys which are F9, F10, the left arrow key, and the right arrow key. Function key F9 enables one to contract the interferogram screen, while function key F10 enables an expansion of the screen display. The left and right arrow keys enable one to rotate data on the display screen to the left or right. By using all four of the single function keys, one can display any range of interferogram points without the need of a special keypad, joystick, or mouse control. These keyboard control functions greatly simplify operation of an FTIR sensor in an outdoor field monitoring application.

Function key F2 enables one to view the Fourier transformation of each collected interferogram. The program default is to display the entire range of the spectrum. This default display range can be expanded using function key F9 to display a selected wavelength range. The function keys, F10, left arrow, and right arrow, can be also be used to contract or rotate the display of the transformed single-beam spectrum.

Function key F3 is used to collect interferograms and store data to a disk file. This display option lists the name of the file, the last interferogram number stored to disk, and whether a known data collection error has occurred. A list of error codes is provided in Table 2. Provisions exist in the software that allow the user to include additional codes in the error table. The program automatically uses the error table to scan a particular interferogram for storage in the scan header and display. The addition of the error code table is extremely useful for laboratory and outdoor passive-remote sensing measurements, because an operator is notified instantly of a possible error condition during data collection. By displaying the error code, the operator can correct a possible problem before the end of the open-path measurement.

Table 2. Error Codes

Error Code Number	Error Code Meaning
1	less than correct # of data points collected by computer for scan
2	A/D overflow
3	centerburst interferogram point position change from last scan
4	centerburst position out of range
5	low signal (A/D gain very low)

Interferogram data stored to disk using function key F3 is formatted as shown in Table 3 and Table 4. This standardized data format contains a global header, an interferogram subfile header, and the

interferogram data. The interferogram data format allows for storage of data points in 8, 16, 32, or 64 bit data representations. Data type information is stored in the global header. The current implementation of the MIDAC software uses a 16-bit data storage to correspond with the number of bits of the analog-to-digital converter.

The global header is divided into general information, sensor information, weather information, and comment information. The addition of weather information for outdoor passive-remote sensing measurement is almost essential for some data collection exercises. Information about the other sensor parameters includes the collection mode, the data type, the scan speed, the resolution, the sampling rate, and the number of zero crossings to sample for each data point.

The scan header contains information that is specific to each collected interferogram. Included in the scan header is the interferogram scan number, the time the interferogram scan was collected, the centerburst point position, the analog-to-digital converter gain setting, the file name, and the number of interferogram scans that were coadded upon data storage. The time clock on the PC is queried before the start of each interferometer scan. This information is converted to ASC format and written as part of the header information for each interferogram scan.

An additional scan header descriptor, which is included in the data format, is the file name information. This data field enables the user to tag the source of single interferograms in the large single file storage format. This descriptor is extensively used in the conversion of data types between the commercial SpectraCalc software (Galactic Industries, Salem, NH) and this remote sensing data format.

Function key F4 in the data collection program is used to display a difference spectrum in real-time on the screen. In this data collection mode, a background interferogram is collected, transformed, and subtracted from all following interferogram scans. The result is a display of the difference spectrum that shows the change in thermal emission profile as a function of time. This display function is extremely useful for open-path optical alignment measurements in which the instrument, vapor cell, and the IR source can be simultaneously adjusted.

Function keys F5 through F8 are used to subtract previously stored calibrated reference spectra from each of the collected transformed input interferograms. When one of these function keys is pressed, the program reads a corresponding disk file name, collects an input interferogram, and displays the result of a spectral subtraction. Up to four different calibrated single-beam reference spectra can be stored and recalled during data collection. It is recommended that the calibration reference spectra be transformed and stored to disk through the use of the commercial Spectracalc program.

4. DATA CONVERSION PROGRAMS

Utility data format conversion programs are an essential requirement for any passive-remote sensing application software package, because several excellent commercial software packages exist that aid in the data analysis. Two computer programs were developed that allow conversion of the data format shown in Table 3 and Table 4 to the standard commercial Spectracalc data format. Remote sensing interferogram data collected with the data collection software can be converted, processed, displayed, and output to a hardcopy device through the use of this commercial software.

The first program converts a specified number of remote-sensing interferograms into a single SpectraCalc format interferogram file. The program requests the user to identify a particular group of interferograms on disk to convert. The program reads each remote sensing interferogram and converts the data to a two's complement binary representation. Data stored on the PC disk has a file name that provides a reference index name that is keyed to the source interferogram number.

A second data conversion program converts multiple SpectraCalc files into the single-remote sensing interferogram file format (Table 3). The SpectraCalc data format does not normally include some of the remote sensing header parameters (i.e., weather information and sensor positioning parameters) for data storage of laboratory measurements. Therefore, this program requires the user to input a number of global header parameters describing the data type for storage of a disk file.

5. DATA ANALYSIS PROGRAMS

Real-time data analysis computer programs have been developed for the Midac interferometer that apply a set of automated pattern recognition methods for the detection of specific chemical vapor species. Fourier transform infrared passive remote sensing applications require that a reference background spectrum be subtracted from open-path field spectra to remove the instrument and background spectral contributions. For many reasons, it is not always possible to obtain a true reference spectrum during passive remote sensing data collections. One practical reason of not being able to obtain a true spectrum is that field sites to be monitored may already be contaminated with the vapor species to be measured. In this case, because the vapor species is always present, one may not be able to obtain an accurate emission reference spectrum that does not also contain the vapor species to be monitored.

During the last several years, research has been conducted to develop a signal processing method for eliminating the need of a background reference spectrum. Digital filter and pattern recognition methodology for automatic detection of atmospheric species was developed that eliminates this background reference problem.¹⁵ The methodology uses a preprocessing strategy called a "matrix filter" and a multiple linear discriminant pattern recognition method to discriminate against various backgrounds. Collected interferogram data is used as the input for the generation of an optimal set

of digital filter and multiple discriminate pattern recognition coefficients. Optimized coefficients are generated based on the number of interferograms classified correctly from a training data set. The reader is referred to the open literature publications referenced that describe the mathematical background for the generation of the digital filter and pattern recognition coefficients. (1-4)

Implementation of the mathematical method described in the references is shown in Figure 3. The computer program enables interferogram data to be collected directly from the interferometer and processed through the algorithm. Implementation of the algorithm requires the storage of one set of digital filter coefficients for each point along the digitized interferogram. A current implementation for the acetone vapors detection requires an average of 17 coefficients from each interferogram point along a 75 point interferogram segment length. Data storage requirements for the acetone filter and pattern recognition coefficients were less than 7 K 32 bit words of storage. One set of digital filter and pattern recognition coefficients is required for identification of each particular vapor species.

Current execution of the computer program on a Dell 486 50 MHz PC allows for the real-time identification of acetone without the need of a reference background subtraction. Each interferogram is segmented, filtered, multiplied by the multiple linear discriminants, and subsequently summed to give a single discriminator output result. The discrimination and data display to the screen is completed in less than 20 msec for a single interferogram scan. As an example, if one uses this implementation of software, then enough processor capability is available, using a moderately fast 486 PC, to simultaneously collect and monitor for the presence of up to five compounds. The software on the 486 PC can identify the five different vapor species on every interferogram at scan rates of up to 5/scans/sec. For Acetone and 2-Butanone, the correct classification percentages have been reported to be over 99%.⁶

Figures 3 and 4 show the real-time computer screen display of two data collection runs. The plot in Figure 3 is a data run that shows the response of the discriminator as a function of time. The x-axis shows the interferogram number collected, while the y-axis is the relative output response of the discriminator. The plot indicates that acetone was present between the collection of interferograms 98 to 143 and also 155 to 189. All of the other interferograms outside of these ranges show that acetone was not present in the field-of-view of the interferometer. The plot in Figure 4 is a collection of 1550 interferograms that were collected when no acetone was present in the field-of-view of the interferometer. All of the individual interferogram discriminant responses are below the zero threshold indicating that no acetone is present.

Figure 3. Pattern Recognition Results from the Real-Time Computer Program

Figure 4. Pattern Recognition Results for a Background Data File

6.

CONCLUSIONS

Passive Fourier transform infrared remote sensing data collection and real-time analysis software has been completed for a commercial interferometer that eliminates the need of a background reference spectrum for open path measurements. Data collection routines written in "C" language code allow the user to collect and display interferograms for later analysis. Data analysis routines were completed to allow for the real-time detection of a particular chemical species from single-scan interferograms using a low-powered IBM PC interfaced to a commercial interferometer. Pattern recognition coefficients for the direct interferogram identification and detection of chemical vapors have been developed and executed on a single scan in less than 20 msec using an IBM-PC 486 50 MHz computer.

APPENDIX A

DESCRIPTION OF COMPUTER PROGRAM OPTION LIST

MIDAC DATA COLLECTION PROGRAM OPTIONS

program MIDCOL --- Midac data collection program operation

(A) To start program type: midcol/f (to collect up to 550
interferograms to a single
file)

or

midcol (to collect up to 3000
interferograms to a single
file)

(B) Program input: The program will request the following:

- (1) a filename to store the data
- (2) 4 lines of input to store comments

(C) The following keys are used to control the program:

KEY	Program Action
-----	-----
F1 (function key #1)	display the collected interferogram to the screen
F2 (function key #2)	display the collected spectrum to the screen
F3 (function key #3)	collect interferograms to a disk file
F4 (function key #4)	collect a background spectrum and subtract all following spectra
F5 (function key #5)	subtract transformed interferogram from spectral disk file f5.fsp
F6 (function key #6)	subtract transformed interferogram from spectral disk file f6.fsp
F7 (function key #7)	subtract transformed interferogram from spectral disk file f7.fsp
F8 (function key #8)	subtract transformed interferogram from spectral disk file f8.fsp
F9 (function key #9)	contract the interferogram display
F10 (function key #10)	expand the interferogram display
left arrow key	move the interferogram to the left on the display screen
right arrow key	move the interferogram to the right on the display screen
End (the key labeled "End")	quit program

MIDAC DATA COLLECTION DATA DISPLAY PROGRAM

program REPLAY -- This program will replay the data collected
by the program MIDCOL.

(A) To begin program type: replay filename (the program name and
a data filename is
required)

example: replay c:\temp1.dat

(B) The following keys are used to control the program:

KEY	Program Action
F1 (function key #1)	display the collected interferogram to the screen
F2 (function key #2)	display the collected spectrum to the screen
F4 (function key #4)	display a background spectrum and subtract all following spectra
F5 (function key #5)	subtract transformed interferogram disk file f5.fsp
F6 (function key #6)	subtract transformed interferogram disk file f6.fsp
F7 (function key #7)	subtract transformed interferogram disk file f7.fsp
F8 (function key #8)	subtract transformed interferogram disk file f8.fsp
F9 (function key #9)	contract the screen display
F10 (function key #10)	expand the screen display
left arrow key	move the screen display to the left
right arrow key	move the screen display to the right
PGUP key	speed up the screen display
PGDOWN key	slow down the screen display
End (the key labeled "End")	quit program

PROGRAM CONVINTF - UTILITY DATA CONVERSION

program CONVINTF --- utility data conversion program

- (a) To start the program type: (1) go to the data directory in
the file to convert is located
(2) TYPE: convintf

example: if the data is a file called nct0018.dat and
located in a directory called "c:\data" and
the source code is in a directory called
"c:\midac\collect", then one would go to the
"c:\data" directory and type---

c:\midac\collect\convintf

- (b) Program input: The program will request the following
information:

- (1) a midcol collected interferogram file to read
- (2) a partial character name to append on the
file name for the output files.
- (3) the starting interferogram number to read
- (4) the ending interferogram number to read
- (5) the format type - 0 = floating point format
1 = SpectraCalc format

example:

- (1) Input the interferogram file name to read: nct0018.dat
- (2) Input a partial character name for output interferogram
filename : aaa
- (3) Input the starting interferogram number to convert: 20
- (4) Input the ending interferogram number to convert: 30
- (5) Input the data format type: 0

Result:

Ten data files will be created in the directory "c:\data"
that will be called aaa0020.fsp to aaa0030.fsp. These file will
contain single interferograms that can be read by the program
SPECTRACALC using the import command.

Blank

APPENDIX B

MIDAC SERVO CONTROL JUMPERS

In order for the Midac data collection program to operate in a correct manner, the servo-board on the Midac interferometer must be jumpered in the following manner.

If one is looking at the back of the Midac board titled "Combo Digital Mirror Drive" board, then one can find a row of jumper pins labeled J5 (on the left) to J1 (on the far right side of the board). The basic purpose of each set of jumper is as follows:

- J5 block - determines if the system scans using either the high speed or low speed electronics
- J4 block - controls the clock oscillator on the board to determine the sampling frequency (by selecting options for both J5 and J4 one can select a wide range of scan speeds) (the range is from 20 KHz to 160 KHz sampling frequency)
- J3 block - these jumpers control the number of fringes for every sampled point. The jumpers allow one to sample a point for every He-Ne laser fringe up to the case of 8 zero crossings for every sampled point.
- J2 block - this block of jumpers sets the scan length of the interferometer. The selectable range of scan lengths correspond from 1/2 to 32 wavenumbers of resolution. The software package SPECTRACALC can use any of the scan lengths up to the maximum value jumpered by J3. For example, if 4 wavenumbers were selected, then SPECTRACALC would be able to collect all resolutions up to 4 wavenumbers (32,8,4). It would not be able to collect resolutions at 2,1, and 1/2 wavenumber.
- J1 block - this set of jumpers delays the start of scan time. These jumpers are used to place the centerburst at various places in the sampled interferogram segment. This set of jumpers allows one to collect either single-sided or double-sided interferograms.

The exact jumper settings are as follows:

J5 - high/low speed option		
pin location	label	meaning
-----	-----	-----
left pin	L	selects the low speed scan option
middle pin	H	selects the high speed scan option
right pin	SW	if this is jumpered, then the switch labeled "SW2" on the "Switchable ADC board" can be used to select the scan speed

J4 - controls sampling speed

pin location	label	meaning
left pin	pins 1&2	20 Khz sampling frequency
second pin	3&4	40 KHz
third pin	5&6	80 KHz
right pin	7&8	160 Khz

J3 - number of zero crossings per sampled point

pin location	label	meaning
left pin	M1	samples every 4th zero crossing
second pin	M2	samples every 8th zero crossing
third pin	L1	samples every other zero crossing
right pin	2L	samples every zero crossing

J2 - selects the scan length from 1/2 to 32 wavenumbers

This block of jumpers selects the scan length. The scan length jumpers are offset by one pin to the left set as compared to the bottom set. The right most possible jumpers select the lowest resolution while the far left jumpers set the highest resolution.

top set of pins	# of points collected (for L1 jumper)	scan resolution
right pins	no option	
second pins	32 K	1/2 wavenumber
third pins	16 K	1 wavenumber
fourth pins	8 K	2 wavenumbers
fifth pins	4 K	4 wavenumbers
sixth pins	2 K	8 wavenumbers
seventh pins	1 K	16 wavenumbers
eight pin	1/2 K	32 wavenumbers
left pins	no option	

J1 - selects the scan delay from the zero path difference

DLY4 is the most significant delay bit while the DLY1 jumper controls the least significant delay bit. The jumper positions for the up position is a "0" or "small delay" while the down position is a "1" or a "large delay".

The switch on the "Switchable ADC board" located at the back of the midac unit are as follows:

switch labeled SW1 --- gives one the ability to connect an external detector.

position up - use internal MCT detector

position down - use an external detector

switch labeled SW2 --- controls the scan speed (if the SW jumper is selected on block J5) This switch

will alternate between different sets of analog filters on the ADC board.

The recommended set of jumper selections of the servo board for use with the data collection program "midcol" is as follows:

- J5 - H or L high speed or low speed scanning options
- J4 - 1,2 20 KHz sampling (recommended)
- J3 - M2 sampling every 8th zero crossing
- J2 - on top - 5th pin from left 4 wavenumber resolution
 on bottom - 6th pin from left
- J1 - delay so that the centerburst is between 40 - 90 points
 from the start of scan
- SW1 - use the internal MCT detector - position "up"
- SW2 - switch position "up"

Midac PC interface board jumper setting:

jumper J1 - set jumper to IRQ2

APPENDIX C

REPLAY PROGRAM

```
/****** program REPLAY *****/
/*
```

```
program REPLAY
```

```
version 4.0
```

This program is used to read interferogram data from disk, display, and FFT for display. This program will be used for data collection for the Midac interferometer.

author: Bob Kroutil

date: June 1992

routines called:

- plotr - plots an interferogram or spectrum
- logoega - prints the CRDEC logo
- draw_axis - draws the axis for the plots for either interferogram or spectra
- cmpfft - computes the fast Fourier transform
- norml - normalizes the spectrum
- Microsoft C graphics routines

```
-----*/
```

```
#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>
#include <graph.h>
#include <math.h>
#include <dos.h>
#include "exreplay.def" /* external definitions for the program replay */
#include "headers.def" /* contains the interferogram data structure */
```

```
/* The following global parameters are the following:
```

- MAXPOINTS= the number of interferogram points
- GH_LIMIT = the number of bytes in the global interferogram header
- SH_LIMIT = the number of points in the subfile interferogram header
- FEND = the key code to exit the program
- FRIGHT = the key code to expand the interferogram display
- FHOME = the key code to reset the interferogram display
- FLEFT = the key code to compress the interferogram display
- FSEL5 = the key code to background subtract disk file f5.fsp
- FSEL6 = the key code to background subtract disk file f6.fsp
- FSEL7 = the key code to background subtract disk file f7.fsp
- FSEL8 = the key code to background subtract disk file f8.fsp
- FINT = the key code to display interferograms
- FSPEC = the key code to display spectra
- FDIFF = the key code for the spectral background subtraction
- ROLLL = the key code to roll the display data to the left
- ROLLR = the key code to roll the display data to the right
- MDLY = increase the screen display time
- LDLY = decrease the screen display time

MIDCOL DATA COLLECTION PROGRAM

```

/***** program MIDCOL *****/

```

```

/*

```

```

    program MIDCOL

```

```

                                Version 3.0

```

This program is used to read interferogram data, display, interferogram data, and Fourier transform the data for display. This program will be used for data collection for the Midac interferometer.

author: Bob Kroutil, Mike Housky

date: August 1992

routines called:

```

    plotr      - plots an interferogram or spectrum
    logoega    - prints the CRDEC logo
    draw_axis  - draws the axis for the plots for either interferogram
                  or spectra
    cmpfft     - computes the fast Fourier transform
    normal     - normalizes the spectrum
    MidAqInit  - initialize the Midac interferometer
    MidAqStartScan - set up scanning for Midac
    Microsoft C graphics routines

```

This software is property of the U.S. Army. The distribution of this code is unlimited. This software can not be sold. The U.S. Army is not responsible for the results obtained through the use of this software.

DATA CONVERSION PROGRAM (SCCONV)

```

/*****
/* program SCCONV                                version 2.0

```

Date: 1 June 1993

Author: Bob Kroutil

This program will read a series of SpectraCalc files and store the results into a binary format interferogram file.

Note: A directory listing file is needed by this program for the filename input. This file can be created by the DOS command "dir *.spc >dirfile" ... where dirfile is the name of the directory file to be used as input to this program. This file should be edited to remove the starting and ending information. A listing example of this directory file can be shown in the supplied file "listfile".

APPENDIX F

DATA CONVERSION PROGRAM (CONVINTF)

```

/***** program CONVINTF *****/

```

```

/*

```

```

    program CONVINTF

```

```

                                version 1.5

```

This program will convert an interferogram from a sequential file type (as created by program MIDCOL) to multiple files that can be read using the SpectraCalc binary floating point format. The program can also output a SpectraCalc data file format file.

author: Bob Kroutil

date: May 1993

APPENDIX G

DATA COLLECTION PROGRAM (MIDCOLV)

```

/***** program MIDCOL *****/
/*

```

```

program MIDCOL

```

```

Version 4.0

```

This program is used to read interferogram data, display, interferogram data, and Fourier transform the data for display. This program will be used for data collection for the Midac interferometer.

author: Bob Kroutil, Mike Housky

date: August 1992

routines called:

```

plotr      - plots an interferogram or spectrum
logoega    - prints the CRDEC logo
draw_axis  - draws the axis for the plots for either interferogram
              or spectra
cmpfft     - computes the fast Fourier transform
normal     - normalizes the spectrum
MidAqInit  - initialize the Midac interferometer
MidAqStartScan - set up scanning for Midac
Microsoft C graphics routines

```

```

APPENDIX I

MIDAC DATA COLLECTION AND PATTERN RECOGNITION PROGRAM FOR IDENTIFYING TWO COMPOUNDS SIMULTANEOUSLY

```

/*****
/*
program MTRX2

This program is a "C" version of the TESTWV program located on the
Silicon Graphics computer. The program will process interferograms
collected on the Midac unit 120 interferometer and display the
result of the filtering and pattern recognition.

author: Bob Kroutil, Mike Housky

date: March 1993 */
