Abstract

An Eulerian and semi-Lagrangian finite element methods for the solution of the two dimensional advection equation were developed. Bilinear rectangular elements were used. Linear stability analysis of the method is given.

1. Introduction

Two photographs appearing in the New York Times (March 28, 1994) show the damage of air pollution near big emission sources. But the problem exists even away from sources since air pollutants can be transported, mainly by advection. Thus air pollution becomes a global problem. This physical phenomenon consists of three major stages (see e.g. Zlatev [1]):

1. emission,
2. transport/advection,
3. transformation during the transport which includes: diffusion, deposition and chemical reactions.

In this paper, we only discuss the transport stage and the solution of the two dimensional advection equation by finite element methods.

2. Finite Element Solution

The two dimensional advection equation is given by

$$\frac{\partial c}{\partial t} = -\frac{\partial}{\partial x}(uc) - \frac{\partial}{\partial y}(vc), \quad x_L \leq x \leq x_R, \quad y_L \leq y \leq y_U, \quad 0 < t \leq T \quad (1)$$

where c is the concentration of a certain pollutant and u and v are the wind velocity components in the x and y directions, respectively. Clearly, when one is interested in several pollutants, the equation is replaced by a system of such equations coupled only via the chemical interaction between species.

The methods for numerical solution of the advection equation can be divided into five groups:

1. Finite differences,
2. Spectral methods,
3. Finite volume,
4. Characteristic-based methods or semi-Lagrangian,
5. Finite elements.

The finite difference methods are most popular and have been analyzed thoroughly (see e.g Richtmeyer and Morton [2]). Spectral methods (see e.g Orszag [3,4]) are used in weather forecasting, but not very much in air pollution. The pseudo spectral methods are of the same group. Here the solution is approximated by a truncated polynomial whose derivatives are substituted in the equation. The spectral methods require periodic boundary conditions. Finite volume or cell method is based on the integral form of the equation. The computational domain is divided into elements (volumes or cells) within which the integration is carried out. This method preserves the property of conservation (see Peyret and Taylor [11]). The semi-Lagrangian methods are not very popular among scientists working with air pollution models, but these are now gaining popularity in weather prediction. "Discretization schemes based on a semi-Lagrangian treatment of advection have elicited considerable interest... since they offer the promise of allowing larger time steps (with no loss of accuracy) than Eulerian-based schemes whose time step length is overly limited by consideration of stability" (see Staniforth and Côté [9]). Semi-Lagrangian methods based on finite difference or finite element spatial discretization were developed.

Here we discuss the finite element approximation to the two dimensional advection equation. Both Eulerian and semi-Lagrangian finite elements will be discussed and tested. Software will be available upon request or electronically via world wide web at the URL address <http://math.nps.navy.mil/~bneta>. The advantage of finite elements is the fact that the discretization can be as easily carried out for nonuniform grids. Thus one can use a fine grid only where the action is and a coarser grid away from there. First order linear one dimensional elements have been previously used, see e.g Pepper et al [5]. We now discuss bilinear finite elements on rectangles. It was shown by Neta and Williams [6] that isosceles triangles with linear basis functions and rectangular bilinear elements are superior to other triangulations and to finite differences. If the grid is uniform, rectangular elements are preferred since Staniforth et al [7] have shown how to evaluate the integrals efficiently and the mass matrix can be replaced by a tensor product of two tridiagonal matrices. If the grid is nonuniform again the rectangular elements are preferred, since the isosceles triangles lose their shape.

3. Bilinear Finite Elements

Discretize the rectangular domain, by introducing the nodes

$$(x_i, y_j), \quad i = 0, 1, \dots, I + 1, \quad j = 0, 1, \dots, J + 1,$$

where

$$x_0 = x_L, x_{I+1} = x_R, y_0 = y_L, y_{J+1} = y_U. \quad (2)$$

Suppose we number the interior nodes

$$n = 1, \dots, IJ \quad (3)$$

from bottom left to top right, see figure 3 for the case $I = 4, J = 3$.

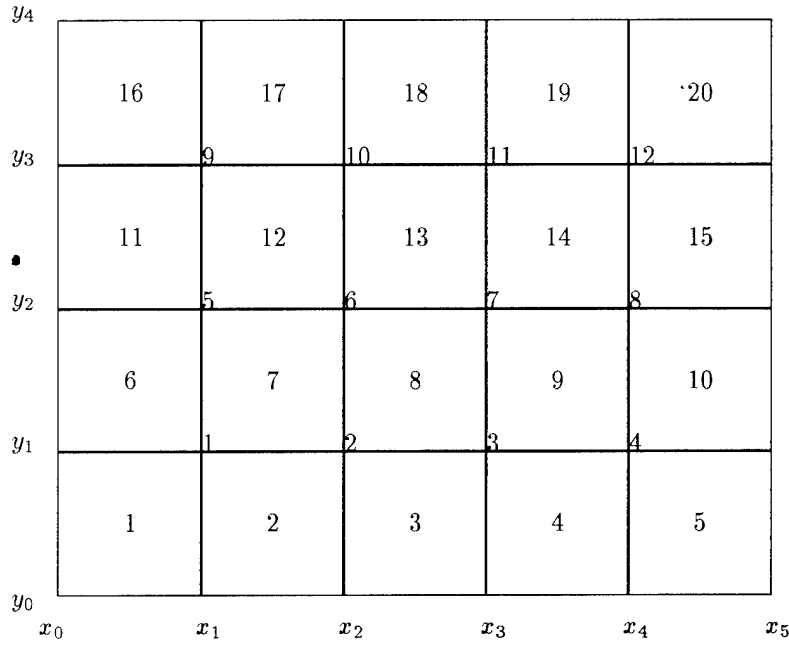

Figure 3: node and element numbering

The number of finite (rectangular) elements is $N_e = (I + 1)(J + 1) = 20$ in this case.

We now define the basis functions $\varphi_m(x, y)$ as bilinear functions on each rectangle, so that

$$\varphi_m(x, y) = \begin{cases} 1 & \text{at node } m \\ 0 & \text{at all other nodes.} \end{cases} \quad (4)$$

To obtain the bilinear basis functions defined on the k^{th} element, we can make a transformation of this rectangle to a square centered at the origin having sides of length 2 (see figure 4).

Figure 4: k^{th} element (top) and its transformed one

The transformation is given by

$$\begin{aligned}\xi &= \frac{2}{x_{l+1}-x_l}x - \frac{x_{l+1}+x_l}{x_{l+1}-x_l} \\ \eta &= \frac{2}{y_{m+1}-y_m}y - \frac{y_{m+1}+y_m}{y_{m+1}-y_m}\end{aligned}\quad (5)$$

and the basis functions in the $\xi - \eta$ domain are given by

$$\begin{aligned}\varphi_A &= \frac{1}{4}(\xi - 1)(\eta - 1) \\ \varphi_B &= -\frac{1}{4}(\xi + 1)(\eta - 1) \\ \varphi_C &= \frac{1}{4}(\xi + 1)(\eta + 1) \\ \varphi_D &= -\frac{1}{4}(\xi - 1)(\eta + 1)\end{aligned}\quad (6)$$

where the subscripts denote the vertex at which $\varphi = 1$. Note that the basis functions are product of the appropriate linear basis functions, i.e.

$$\varphi_A(x, y) = e_l(x)e_m(y)$$

where

$$e_i(\theta) = \frac{\theta_{i+1} - \theta}{\theta_{i+1} - \theta_i}.$$

This property is crucial to efficiently evaluating the integrals (Staniforth et al [7]).

The approximate problem becomes

$$M\dot{c} - Kc = b \quad (7)$$

where the entries of the matrices M , and K are given by

$$M_{ij} = \int \int_R \varphi_j \varphi_i dx dy \quad (8)$$

$$K_{ij} = \int \int_R \left(u \varphi_j \frac{\partial \varphi_i}{\partial x} + v \varphi_j \frac{\partial \varphi_i}{\partial y} \right) dx dy. \quad (9)$$

The vector c gives the concentrations at grid points at any time t , and b gives the boundary data

$$b_j = - \sum_{i=1}^{N_c} c_i(t) \left[\int_{y_L}^{y_U} (u \varphi_i \varphi_j) \Big|_{x_L}^{x_R} dy + \int_{x_L}^{x_R} (v \varphi_i \varphi_j) \Big|_{y_L}^{y_U} dx \right] \quad (10)$$

Since u, v are in general functions of x and y , we use numerical quadrature to evaluate K_{ij} . The quadrature we employed in our case is the two point open type, i.e.

$$\int_a^b f(x) dx = \frac{3h}{2} [f(a+h) + f(a+2h)], \quad (11)$$

where

$$h = \frac{b-a}{3}$$

and the error term is given by

$$\frac{3}{4}h^2 f''(\xi).$$

Thus for the first integral in K_{ij} we get

$$\iint_R u \varphi_j \frac{\partial \varphi_i}{\partial x} dx dy = \sum_{k=1}^{N_e} \int_{x_i}^{x_{i+1}} \int_{y_m}^{y_{m+1}} u \varphi_j \frac{\partial \varphi_i}{\partial x} dx dy. \quad (12)$$

Now use the quadrature for each integral and centered differences for the partial derivatives to get

$$\begin{aligned} \sum_{k=1}^{N_e} \frac{3}{2} h_x \frac{3}{2} h_y \left\{ \right. & u(E) \varphi_j(E) \frac{\varphi_i(P) - \varphi_i(Q)}{2\delta} + \\ & u(H) \varphi_j(H) \frac{\varphi_i(Y) - \varphi_i(Z)}{2\delta} + \\ & u(F) \varphi_j(F) \frac{\varphi_i(V) - \varphi_i(S)}{2\delta} + \\ & \left. u(G) \varphi_j(G) \frac{\varphi_i(W) - \varphi_i(X)}{2\delta} \right\} \end{aligned} \quad (13)$$

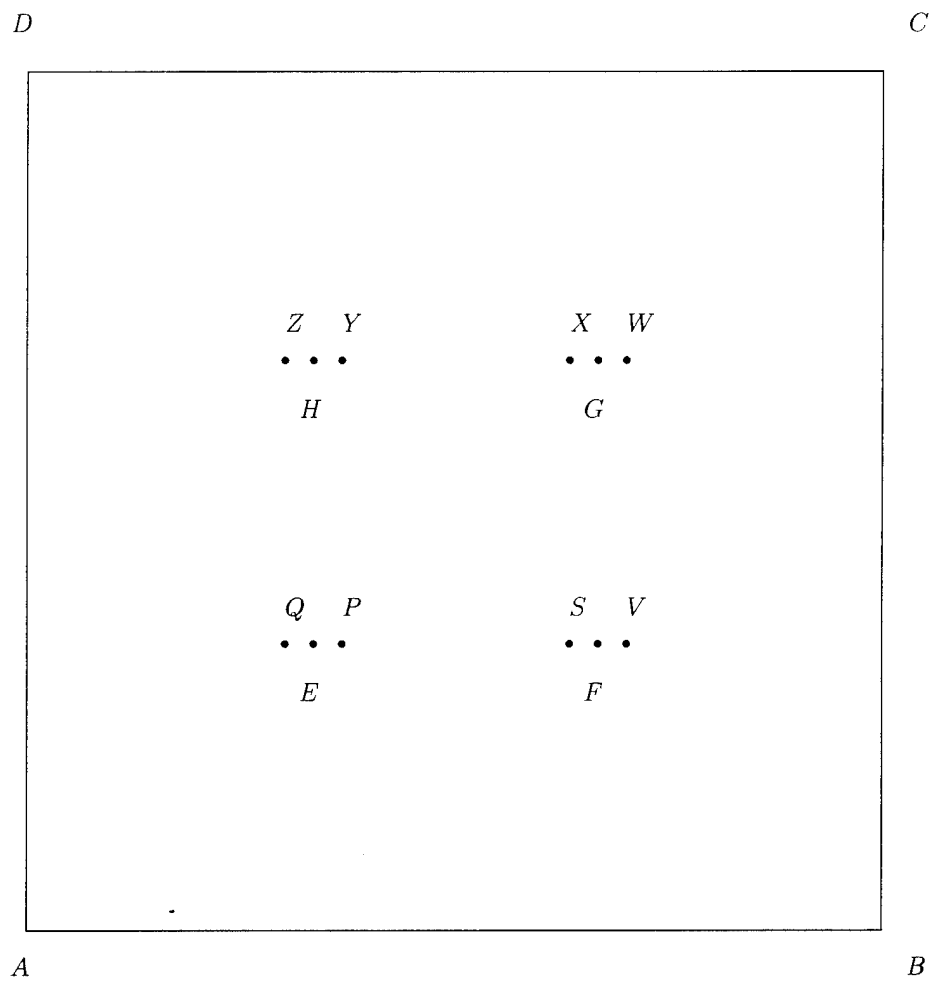

Figure 5: location of quadrature nodes

where

$$h_x = \frac{x_{l+1} - x_l}{3}, \quad h_y = \frac{y_{m+1} - y_m}{3} \quad (14)$$

and δ , the spacing for the centered differences was arbitrarily chosen as

$$\delta = .05(x_{l+1} - x_l). \quad (15)$$

Similarly, we can approximate the second integral in K_{ij} except that now the points will be $\delta = .05(y_{m+1} - y_m)$ units above and below the four points E, F, G, H .

4. Semi-Lagrangian Finite Elements

Semi-Lagrangian schemes belong to the general class of upwinding methods. For hyperbolic equations, upwinding methods incorporate characteristic information into the numerical method. In Lagrangian schemes, the evolution of the system is monitored by following specific fluid particles through space. As a result, Lagrangian schemes allow larger time steps than Eulerian. The problem with fully Lagrangian schemes is that an initially regularly spaced set of particles will generally evolve into irregularly spaced particles. As a result, some important features in the flow may not be captured properly. Semi-Lagrangian schemes combine the best of both worlds: the regular resolution of an Eulerian scheme and the high stability of a Lagrangian method. The idea is to choose a different set of particles such that at the end of the time step, they arrive at points on a regular Cartesian grid. The departure points of the particles are determined by an iterative process using the interpolated velocity vector from the previous time.

A semi-Lagrangian formulation of (1)

$$\frac{c^+ - c^-}{2\Delta t} + \frac{1}{2} [(cu_x + cv_y)^+ (cu_x + cv_y)^-] = 0 \quad (16)$$

where c^+ is the solution at the grid points at time $t + \Delta t$, c^- is the solution at time $(t - \Delta t)$ at those points arriving at the grid points at time $t + \Delta t$. Since one requires two previous time levels, the program uses Matsuno's (see e.g. Haltiner and Williams [12]) method to get the first time step.

In the appendix, we bring plots of the solution for the cone test (see e.g. Zlatev [1]) using Eulerian finite elements with explicit, Crank-Nicholson and fully implicit time discretizations as well as the semi-Lagrangian method.

5. Stability Analysis

There are four rectangles having a vertex in common, as indicated in the next figure. The approximate solution at the vertices of the rectangles may be obtained by solving the following first order ordinary differential equation (see Neta and Williams [6] for the one dimensional advection case).

Figure 6: rectangular elements having a common vertex

$$\begin{aligned}
\dot{c}(P) &+ \frac{1}{4} [\dot{c}(G) + \dot{c}(B) + \dot{c}(D) + \dot{c}(E)] \\
&+ \frac{1}{16} [\dot{c}(F) + \dot{c}(H) + \dot{c}(A) + \dot{c}(R)] \\
&+ \frac{3}{16} u \frac{1}{\Delta x} \{c(H) - c(F) + c(R) - c(A) + 4[c(E) - c(D)]\} \\
&+ \frac{3}{16} v \frac{1}{\Delta y} \{c(H) - c(R) + c(F) - c(A) + 4[c(G) - c(B)]\} = 0
\end{aligned} \tag{17}$$

Substitute a Fourier mode

$$c(x, y, t) = A(t)e^{i(\mu x + \nu y)} \tag{18}$$

in (17) to get

$$\begin{aligned}
\dot{A}(t) \left\{ 1 + \frac{1}{4}(2 \cos \mu \Delta x + 2 \cos \nu \Delta y) + \frac{1}{16} 4 \cos \mu \Delta x \cos \nu \Delta y \right\} \\
+ \frac{3}{16} \frac{u}{\Delta x} A(t) \left\{ 4 + 2 \cos \nu \Delta y \right\} 2i \sin \mu \Delta x \\
+ \frac{3}{16} \frac{v}{\Delta y} A(t) \left\{ 4 + 2 \cos \mu \Delta x \right\} 2i \sin \nu \Delta y = 0
\end{aligned} \tag{19}$$

or

$$\dot{A}(t) + 3i \left\{ \frac{u}{\Delta x} \frac{\sin \mu \Delta x}{2 + \cos \mu \Delta x} + \frac{v}{\Delta y} \frac{\sin \nu \Delta y}{2 + \cos \nu \Delta y} \right\} A(t) = 0. \quad (20)$$

For the special case of flow along the x or y axis one of the terms in braces will drop. For flow along the diagonal

$$\frac{u}{v} = \frac{\Delta y}{\Delta x} \quad (21)$$

we have

$$\dot{A}(t) + 3i \frac{u}{\Delta x} \left\{ \frac{\sin \mu \Delta x}{2 + \cos \mu \Delta x} + \frac{\sin \nu \Delta y}{2 + \cos \nu \Delta y} \right\} A(t) = 0. \quad (22)$$

In general, the ordinary differential equation becomes

$$\dot{A}(t) + i\sigma A(t) = 0, \quad (23)$$

where σ is 3 times the term in braces in (20). For the leap-frog time discretization

$$A_{n+1} - A_{n-1} + 2i\sigma \Delta t A_n = 0 \quad (24)$$

we have

$$\lambda_{1,2} = -i\sigma \Delta t \pm \sqrt{1 - \sigma^2 (\Delta t)^2}, \quad (25)$$

and thus for stability ($|\lambda| \leq 1$), we must have

$$|\sigma \Delta t| \leq 1. \quad (26)$$

If we let

$$U = \max(|u|, |v|) \quad (27)$$

$$\delta = \min(\Delta x, \Delta y)$$

then the method is stable if

$$\frac{\Delta t}{\delta} \leq \frac{2}{3U}. \quad (28)$$

This is the CFL condition.

6. Fourier Transform

The Fourier transform of a function $c(x, y, t)$ is given by

$$\mathcal{F}\{c\} \hat{c}(k, l, t) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} c(x, y, t) e^{-i(kx+ly)} dx dy \quad (29)$$

Taking the Fourier transform of the linearization of (1), one gets the initial value problem

$$\frac{d\hat{c}}{dt} + i(ku + lv)\hat{c} = 0, \quad (30)$$

$$\hat{c}(k, l, 0) = \hat{c}_0(k, l). \quad (31)$$

The solution of which is given by

$$\hat{c}(k, l, t) = \hat{c}_0(k, l)e^{i\nu t}, \quad (32)$$

where

$$\nu = -(ku + lv). \quad (33)$$

To get the solution $c(x, y, t)$ in the physical domain, we have to take the inverse Fourier transform and use the convolution theorem. This yields the well known solution

$$c(x, y, t) = c_0(x - ut, y - vt). \quad (34)$$

In order to obtain the Fourier transform of the approximate solution, recall that

$$\int_{-\infty}^{\infty} u(x + \Delta x, y, t)e^{-ikx} dx = e^{ik\Delta x} \hat{u}(k, y, t). \quad (35)$$

Applying Fourier transform to (17), one gets

$$\frac{\hat{c}}{dt} + \left[iu \frac{3}{\Delta x} \frac{\sin k\Delta x}{2 + \cos k\Delta x} + iv \frac{3}{\Delta y} \frac{\sin l\Delta y}{2 + \cos l\Delta y} \right] \hat{c} = 0. \quad (36)$$

Compare (36) and (30), to find that k, l are replaced by σ_x, σ_y respectively, where

$$\sigma_x = \frac{3}{\Delta x} \frac{\sin k\Delta x}{2 + \cos k\Delta x}, \quad \sigma_y = \frac{3}{\Delta y} \frac{\sin l\Delta y}{2 + \cos l\Delta y}.$$

Note that as $\Delta x \rightarrow 0$, $\sigma_x \rightarrow k$ and as $\Delta y \rightarrow 0$, $\sigma_y \rightarrow l$, thus at the limit (36) becomes (30). In fact

$$\sigma_x \sim k - \frac{1}{180}k^5\Delta x^4 - \frac{1}{1512}k^7\Delta x^6 + O(k^9)$$

$$\sigma_y \sim l - \frac{1}{180}l^5\Delta y^4 - \frac{1}{1512}l^7\Delta y^6 + O(l^9)$$

The solution of (36) with the same initial value is given by

$$\hat{c}(k, l, t) = \hat{c}_0(k, l)e^{i\hat{\nu}t}, \quad (37)$$

where

$$\hat{\nu} = -(\sigma_x u + \sigma_y v). \quad (38)$$

The inverse transform is given by

$$c(x, y, t) = \frac{1}{4\pi^2} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \hat{c}_0(k, l) e^{-i(u\sigma_x + v\sigma_y)t} e^{i(kx + ly)} dk dl \quad (39)$$

or by using convolution

$$c(x, y, t) = c_0 * \mathcal{F}^{-1} \left\{ e^{-i(u\sigma_x + v\sigma_y)t} \right\}. \quad (40)$$

7. Program Notes

The program can run semi-Lagrangian as well as Eulerian finite elements. In the Eulerian case the time differencing is one of the following:

- Explicit
- Crank Nicholson
- fully implicit

where the resulting linear system of equations is solved by the conjugate gradient method with symmetric SOR preconditioning (see e.g. Ortega [15]).

The four lines of input contain:

1. I, J
2. x_L, x_R, y_L, y_U
3. $\Delta t, T$ (final time of integration), IPLOT (number of time steps between solution plots).
4. θ (a parameter dictating the time integrator). This is needed only for Eulerian finite elements.

Here we include the input file and the programs used to test the Eulerian and semi-Lagrangian finite element methods. First we give the input file. The first line contains the number of grid points in the x and y directions. The second line describe the rectangular domain on which the problem is solved. The interval for x is given followed by the interval for y . The third line gives the time step Δt , the final time of integration, and the number of time steps between plots. For Eulerian finite elements, we have a fourth line with the value of θ .

Here is the input file for the explicit time discretization.

count=nx*ny;
jj=1;
while (j < ny)
[aa,count]=fscanf(fid,'%e%e%e%e',nx);
ab(jj:jj+count-1)=aa;
j=j+1;
jj=jj+count;
end;
u=reshape(ab,nx,ny);
v=u';
c=contour(v,10);
clabel(c);
    title(['concentration after ',num2str(hour),' revolutions'])
    print c -dps -append
i=i+1;
j=0;
end;
```

Conclusion

We have developed a bilinear finite element Fortran code to solve the two dimensional advection equation on a unix-based SUN Sparc 10 workstation. The stability of the method is analyzed. We have also developed a semi-Lagrangian finite element code. These codes were experimented with in solving the cone test problem. It is clear from the plots that the semi-Lagrangian is superior to the Eulerian finite elements, since the cone rotates back to its position without leaving a noisy trail behind.
