Abstract

This paper focuses on using Audiometric Data Base Analysis (ADBA) to evaluate the effectiveness of the hearing conservation program (HCP) at eight Air Force Bases. The primary goal is to evaluate the effectiveness of the HCP for all eight bases combined. The secondary goal was determining which groups of personnel are experiencing the most variability in their hearing threshold levels (HTLs).

The ADBA results revealed that the total group exhibited a program that was between marginal and unacceptable. Breaking the total group's audiometric data into smaller groups did not reveal a significantly different variability by group with the exception of gender. Females had significantly less variability in their mean HTLs when compared to males.

The standard deviation of differences of HTLs measure did not give similar results to the other measures. The use of the standard deviation of difference of HTLs measure is not recommended for use under the present guidelines.

An overall distribution of TWAs (time weighted averages) for the total group showed a fairly normal distribution with the 50th percentile at 85 dBA (A frequency-weighted sound pressure level). The 10th percentile is 77 dBA and 90th percentile is 94 dBA for the total population.

Introduction

Currently, noise exposure and audiometric data are collected and maintained for all personnel in the United States Air Force (USAF) HCP. The audiometric data are maintained in a central database. The noise exposure data are kept in separate databases at each Air Force Base (AFB). Individual's noise exposure and audiometric data are maintained in their medical records and evaluated but no group analysis is routinely done. The goal of this study was to merge the sound survey data from each database with the audiometric data and do an overall quality assurance review of the HCPs included in the study.

The data for the study came from several sources. The audiometric data (70,777 records on 14,166 individuals) came from the Hearing Conservation Data Registry (HCDR) in the Occupational and Environmental Health Directorate, Armstrong Laboratory, Brooks AFB, TX. Noise exposure data came from databases at each base. The medium size bases use a database called BEEKEEPER to store noise exposure data. The large bases use a database called PHOENIX to store the noise exposure data. In addition, the required personnel data were obtained from the Military Personnel Center, Randolph AFB TX.

The primary method for evaluating the HCPs is the ADBA protocol defined in the Draft American National Standard Institute (ANSI) Standard S12.13-1991 - Evaluating the Effectiveness of Hearing Conservation Programs. ADBA evaluates variability in HTLs using three different methods.⁴ The results can be used to classify the overall HCP as acceptable, marginal or unacceptable.

Each ADBA procedure is discussed and used to evaluate the USAF data studied. First, an overall quality evaluation is carried out for the total group. Then the individual data groups are evaluated. Finally, the findings for the total and subset data bases are presented and a comparison of the findings across data bases are discussed.

Since the standard is a draft publication for use and comment, this is an excellent time to evaluate the USAF programs with the different methods and see how they compare and provide comments to the ANSI working group.

Background

Prevention of occupational hearing loss is the primary goal of a HCP. However to prevent hearing loss, HCP personnel need to be able to detect developing Noise Induced Permanent Threshold Shifts (NIPTS) before significant hearing loss occurs. Audiometric Data Base Analysis (ADBA) offers the potential for detecting problems in the HCP (such as noise induced hearing loss) quickly before significant hearing loss can occur.

ADBA has several other advantages. It provides data that can be used to develop simple charts and graphs that may be used in education sessions for presenting to supervisors and employees the effectiveness of the HCP in their department, providing motivation for the HCP. ADBA has also been used by HCP personnel to compare the effectiveness of different hearing protective devices and to demonstrate to management the effectiveness of, or lack of, dollars spent on the HCP.¹¹

The only valid objective indication of whether a HCP is succeeding in preventing occupational hearing loss is audiometric results for the noise-exposed employees. Review of selected individual audiometric records provides information on the hearing changes for

the individuals. However, this review process does not give an overall picture of how well a group of workers are being protected.¹¹

The ADBA procedures are based on various ways of measuring year-to-year audiometric variability. A properly protected noise-exposed population should not have any more variability in their hearing threshold levels than for a population not exposed to significant occupational noise exposure assuming all other sources of variability are controlled.⁴ For a more detailed discussion of ADBA please refer to previous publications in the literature.^{5-10,12}

The sources of audiometric variability include normal fluctuations in the responsiveness of individuals, inconsistencies in equipment calibration, testing methods used and true threshold changes due to temporary or permanent hearing loss.¹¹ With personnel moving between bases on a regular schedule every three to five years, these variables may be hard to control and assess. Therefore, the movement of personnel may be a major source of variability in HTLs.

USAF HCP

The USAF HCP is administered by Aerospace Medicine. A three pronged approach is used. Bioenvironmental Engineering conducts sound level meter and noise dosimetry surveys and evaluates noise controls. Military Public Health conducts supervisor training and issues hearing protective devices. Physical Exams provide audiometric exams. Each group is part of Aerospace Medicine which coordinates these efforts through the occupational medicine working group.^{1,2}

The USAF does not follow the requirements of the Occupational Safety and Health Administration (OSHA) noise standard. It uses different criteria. To describe the USAF HCP criteria, a few definitions are needed. First, the criterion level is the 8 hour equivalent that results in a 100% noise dose measurement. Next, exchange rate defines the increase or decrease in sound level for a corresponding halving or doubling of exposure time. The exchange rate is also called the trading ratio or doubling rate. Finally, $L_{eq,T}$ is the equivalent continuous A frequency-weighted sound level over a time T. If T is 8 hours, $L_{eq,8}$ becomes the time-weighted average, or TWA.

The USAF program presently uses a criterion level of 85 dBA and a 3 dB (decibel) exchange rate. Individuals are allowed noise exposures unprotected less than 85 dBA. USAF members are placed on the HCP if the TWA equals or exceeds 85 dBA and hearing protection is required. Previously, the USAF used a criterion level of 84 dBA and a 4 dB exchange rate. The use of the current criterion level and exchange rate started in December 1993.

Characteristics of the Studied Air Force Bases

Eight AFBs were selected for this study, two large bases and six medium size bases. The two large bases were Kelly AFB (San Antonio, TX) and Robins AFB (Warner-Robins, GA). Both bases are primarily air logistic centers and perform depo level maintenance on aircraft. The six medium size bases were Langley AFB (Hampton VA), Shaw AFB (Sumter, SC), Seymour-Johnson AFB (Goldsboro, NC), Pope AFB (Fayetteville, NC), Charleston AFB (Charleston, SC) and Randolph AFB (Universal City, TX). Langley, Shaw, Seymour-Johnson and Pope AFBs are primarily fighter bases. Charleston AFB is primarily a transport base. Randolph AFB is primarily a pilot training base.

Group Descriptive Statistics

To assess the HCP programs, only personnel with at least four sequential audiograms were used. This limited the total group size considerably (14,166 to 6655 individuals). The last four sequential tests are renumbered so the most recent test is test 4 and the next most recent test is test 3, etc.

The audiometric data are divided into several different groups for comparison purposes. First, a total group is formulated that includes personnel from all eight AFBs. Next, the total group is split into military and civilian groups and into male and female groups. Additionally, the total group is split into groups based on ethnic classifications. Last, the total group is broken down further into individual AFB data bases. Appendix C lists group descriptive statistics for each group. Statistics listed include the number of USAF personnel included in each group and the average age and average service length for each test.

ADBA Criteria

In applying the ADBA procedures defined by the Draft ANSI S12.13-1991 standard, the data should "ideally" (but not an absolute requirement) meet certain requirements. The audiograms should have been given approximately yearly with the maximum interval between tests less than eighteen months. The population data base should be restricted to the same subjects over the period of analysis. A minimum number of audiograms is suggested for each subject of the population and the population should be representative of all employees, with a minimum of 30 people per analysis group. The audiometric data should be collected during the work shift, so temporary threshold shifts as well as developing permanent threshold shifts can be detected by the ADBA procedures. Finally

the data should be checked for possible contamination (includes re-test results, obviously major shifts in HTLs across test frequencies, etc.) before analysis.⁴

The ANSI standard presents three measures of variability in hearing threshold levels for use when comparing sequential audiograms. The three measures are:

1. Percent Worse Sequential (%W_S): percent of population showing a 15 dB shift toward worse hearing in either ear at any test frequency (0.5 to 6 kilohertz, kHz) in sequential test comparisons.

2. Percent Better or Worse Sequential (%BW_S): percent of population showing a 15 dB shift toward better or worse hearing in either ear at any test frequency (0.5 to 6 kHz) in sequential test comparisons.

3. Standard Deviation of Differences in Hearing Threshold Levels (S_X): is calculated using the differences averaged across ears, $\bar{X}$, at the audiometric test frequencies of 0.5 to 6 kHz between sequential hearing thresholds of N individuals. The standard deviation, S_X , is calculated as follows:

$$S_x = \sqrt{\frac{\sum X^2 - \frac{(\sum X)^2}{N}}{N-1}},$$

where X is the difference between sequentially averaged hearing thresholds, and N is the number of individuals.

Criterion ranges for evaluating the results from applying the three ADBA measures are given in appendix A, tables 1 and 2. The criteria utilized depends on which set of

sequential audiograms are being compared, the true first four (1-2, 2-3 and 3-4) for a population or later audiograms (4-5, 5-6, 6-7, 7-8, etc.). Table 1 is for the %W_S and %BW_S measures. Table 2 is for the S_X measure at individual test frequencies.⁴

Results

Appendix A, table 3 shows the results of applying the ADBA procedures to the last four tests for the total group and sub-groups using the %W_S and %BW_S measures. Also indicated in the table is the 95% confidence intervals for each measure calculated.

Appendix A, table 4 presents the results for the S_X measure for the total group. Appendix A, table 5 shows the mean HTLs vs. mean age and frequency for each group.

The data for appendix A, tables 3, 4 and 5 are taken from the ADBA outputs. The ADBA outputs were generated using the PC-Hearval¹³ Audiometric Data Base Analysis Program for use with PC-compatible computers. Appendix D presents the first page output of the CMPALL.EXE program that generates baseline and sequential test comparison results. The different overall comparison criteria are shown. The data discussed herein (%W_S and %BW_S) corresponds to category 8, which is shown blocked in.

Appendix E presents, pages E-1 to E-3, the shift results for all eight AFBs for the test comparisons 1-2, 2-3 and 3-4. As an example, on page E-1, the shift data (in 5 dB increments for the left, right and combined ear HTLs) is shown. In addition, the mean and standard deviation of the shift data is shown. Finally, at the bottom of the page is the summed shift data by category. As noted earlier, category 8 presents the %W_S and %BW_S data presented herein.

Total Group and Individual AFB Groups

Appendix B, figure 1 presents the %W_s data for the total group and each individual AFB. Looking at figure 1, the HCP ratings are generally in the marginal range. The total group's %W_s measure varied from 23 to 27%. Most of the data are overlapping and it is hard to distinguish between the individual groups. The exception is the Seymour-Johnson AFB data. The data from Seymour-Johnson exhibited the smallest group size (n=80) for comparison and the highest variability in HTLs (%W_s from 20 to 45%).

Appendix B, figure 2 presents the %BW_s data for total group and each individual AFB. Most of these data points are in the lower unacceptable to marginal range. The total group has a %BW_s measure ranging from 40 to 43%. Once again the Seymour-Johnson AFB data are generally higher than the rest of the data (41 to 54%). Charleston and Shaw AFBs also have higher %BW_s measures than the total group (45 to 48 % and 45 to 50%). The rest of the bases have similar %BW_s measures to the total group. Based on the %W_s and %BW_s measures, the total group and most of the individual AFB group findings are in the upper marginal to lower unacceptable range. Appendix E contains the shift results from the total group of all eight AFBs. Appendix F presents the shift results for each individual AFB.

Sx Measure

Appendix A, table 4 presents the results for the S_x measure for the total group. Using the S_x measure, shown in appendix B, figure 3, the total group has an acceptable HCP (all frequencies have lower standard deviations than listed in appendix A, table 2). The individual AFB groups have similar S_x measures as the total group. The failure of the S_x measure to identify unacceptable HCPs has been noted by the ANSI S12.13 working group, and the standard deviation of differences ADBA measure was therefore dropped. Therefore, the S_x findings will not be discussed further.

Civilian vs. Military Groups

Appendix B, figures 4 and 5 are plots of the %W_s and %BW_s measures for the total group split into civilian and military groups. These groups have large populations, so their 95% CIs are fairly small. Both groups present similar variability results with the %W_s in the 22 to 28% range for civilians and 23 to 25% range for military. The %BW_s findings are also similar, with ranges of 41 to 42% and 37 to 44% for the civilian and military groups. Since the civilian group is much less mobile than the military group this would suggest that movement between bases may not be a major source of the variability observed in the USAF HCP. Appendix G presents the shift results for the military and civilian groups.

Gender Groups

Appendix B, figures 6 and 7 are plots of the %W_s and %BW_s measures for the total group separated by gender. The female group is considerably smaller than the male group (365 vs. 6207 individuals). In general, the female group has less variability in its mean HTLs (%W_s of 18 to 19 % vs. 24 to 27% and %BW_s of 34 to 35% vs. 40 to 45%). The 95% CIs for both groups do not overlap. The female group is primarily in the marginal range and the male group overlaps both the marginal and unacceptable range. The shift results for the male and female groups are located in appendix H.

Ethnic Groups

Appendix B, figures 8 and 9 separates the total group into different ethnic groups. Only three ethnic groups had large enough numbers to be considered, blacks, hispanics and whites. All the groups exhibit very similar variability with the %W_s and %BW_s measures matching the total group's measures. The %W_s measure varied from 24 to 26 % for whites, 21 to 24% for blacks and 20 to 27% for hispanics. The %BW_s measure varied

from 39 to 45% for whites, 39 to 41% for blacks and 40 to 41% for hispanics. Appendix I presents the shift results for each ethnic group.

Mean HTLs vs. Audiometric Test Frequency

Another way of looking at the data analyzed is presented in appendix B, figures 10-25. In figure 10, the mean HTLs are plotted vs. test frequency for the total group for the population's last four tests. This type of plot presents one view of the data. It provides information with respect to the population's hearing characteristics over time by audiometric test frequency. Similarly in figures 11-18, the mean HTLs are plotted vs. test frequency for the population of each individual AFB. In Fig 19-25, the mean HTLs are plotted vs. test frequency for remaining groups (civilian vs. military, gender and ethnic).

Mean HTLs vs. the Population's Mean Age

In figures 26-41, the same data base is plotted as mean HTLs vs. mean age by audiometric test frequency for the total group and each sub-group. This type of data configuration provides useful information including: the mean time between tests, the average age of the population at each test and possible calibration errors (significant shifting in HTLs between tests at one or more test frequencies).

Noise Exposure Distributions

The audiometric data obtained from the HCDR exhibited a noise exposure value field. A closer inspection of the values for this noise exposure data found it to be unreliable. Some bases had no information entered and others had the same value for all personnel.

Therefore, instead of trying to use this questionable data, noise exposure data were directly collected from databases at each AFB studied. Appendix B, figure 42 presents a cumulative distribution plot of the TWA data for the total group representing all eight AFBs. TWAs were determined by work area. Each work area has at least one eight-hour

TWA and some have as many as sixty-five. Over seven hundred work areas are included in this overall distribution. The median of the total group's cumulative TWA distribution was approximately 85 dBA. The 10th percentile is 77 dBA and 90th percentile is 94 dBA. It is noted that this distribution is based primarily on the estimated TWAs that were determined using the previous 4 dB exchange rate.

Similar plots of the distribution of TWAs for each base are in appendix B, figures 43-50. Charleston, Kelly, Robins and Seymour-Johnson AFBs have medians similar to the total group in the 84-85 dBA range. Pope AFB's median is slightly lower at 82 dBA. The remaining AFBs, Shaw, Langley and Randolph, have higher medians of 87, 88 and 90 dBA respectively.

Conclusions and Recommendations

This paper focused on using ADBA to evaluate the HCPs at eight Air Force Bases. The ADBA results for the total data base studied classify the USAF HCP as unacceptable to marginal. Breaking the overall data into individual AFB groups did not reveal a group with significantly different variability from the total group. The exception being that females within data bases exhibit significantly less variability in their HTLs as compared to males.

An overall distribution of TWAs for the total group shows a fairly normal distribution with the 50th percentile at 85 dBA. The 10th percentile is 77 dBA and 90th percentile is 94 dBA for the total population.

The standard deviation of differences ANSI S12.13 measure failed to provide similar results to those found using the %W_s and %BW_s measures. Therefore the use of the

standard deviation of difference of HTLs measure is not recommended in attempting to evaluate the effectiveness of HCPs in general.

Since ADBA findings yielded a program classification of unacceptable to marginal, it is recommended that the source or sources of the identified high variability in USAF audiometric data be investigated further.

CATEGORY 16: MORE THAN 20 DB CHANGE AT 3 4 6 OR 8

MORE THAN 10 DB CHANGE AT 5 1 OR

MORE THAN 15 DB CHANGE AT 2 OR

MORE THAN 20 DB CHANGE AT 3 4 OR 6

NOTE -- ALL TESTS ARE MADE FOR EITHER EAR, NOT COMBINED EARS (IE. CORRESPONDING FREQUENCY LEVELS ARE NOT AVERAGED TOGETHER TO GET A SINGLE NUMBER. THE EARS ARE EXAMINED SEPARATELY.)

NOTE -- MANY PAIRS OF THE CATEGORIES WILL GIVE IDENTICAL RESULTS BECAUSE NO READING WAS MADE AT THE 8K FREQUENCY LEVEL.
