FOREWORD

This project developed a plan for conducting recurring surveys of Defense Logistics Agency customers, in support of the DLA Corporate Customer Assessment Team. The primary product was a sampling plan, including stratification of customers by Military Service or Federal Agency and by commodity purchased from DLA, and sample size calculations for each stratum. The secondary product was a customer data base, identifying customers by activity name, major Service or Agency, mailing address, and Department of Defense Activity Address Code (DoDAAC). Number of requisitions submitted and the dollar value of those requisitions are included for each customer, for each commodity, using fiscal year 1994 data. While the data base was initially developed to provide required address information for mailing customer satisfaction surveys, it is very useful in examining requisition data on individual customers and groups of specific customer types, both within and across individual Inventory Control Points.

In addition to these two products, the project examined survey instruments, recommended annual update of the customer address base, identified alternative sources of data, and assessed additional customer types to consider in future survey development.

EXECUTIVE SUMMARY

The Defense Logistics Agency (DLA) Quality Council recognized the need to ensure high customer satisfaction with DLA goods and services. The Council established the Inventory Control Point Corporate Customer Assessment Team in December 1991, tasked with developing a continuing program to assess and improve customer satisfaction. The first step in this effort is an assessment of current levels of customer satisfaction. The Corporate Customer Assessment Team designed a survey instrument to develop initial customer satisfaction information.

Several challenges had to be met before a successful survey could be initiated. The most basic issue was how to define and identify a DLA customer. Second, a stratification process was required, to assemble individual customers into groups having similar logistics requirements. A statistical sampling plan was then necessary to select representative customers to be surveyed, to determine the customer satisfaction level for each type of customer. Finally, a data base of customer information should provide mailing information for the surveys, and historical data on the volume of business each customer has conducted with DLA.

This project addressed all of these issues, and delivered the following major products:

- a customer stratification plan, identifying customers by military branch or federal agency, and by commodity purchased;
- a statistical sampling plan, allowing recurring surveys to accurately assess customer satisfaction levels;
- a customer information data base, providing customer identification, mailing information, and volume of business in each commodity, both by the number of requisitions submitted and the dollar value of those requisitions.

The report recommends annual customer surveys, and annual updates to the customer information data base. It also identifies alternative sources of data and additional customer types to be included in future surveys.

SECTION 1

INTRODUCTION

1.1 BACKGROUND

The Inventory Control Point (ICP) Corporate Customer Assessment Team is to conduct surveys of Defense Logistics Agency (DLA) customers in support of the DLA Corporate Customer Assessment Program. A previous DLA Operations Research Office (DORO) project, DLA-93-P20355, describes initial efforts to identify customers for participation in focus groups and to assist in the development of a survey instrument. Based on the recommendations of that study, the Plans Team of the Office of Plans and Policy Integration (CAIC) requested that DORO refine the segmentation of customers into survey groups, and provide a sampling plan and customer address data base to support a CAIC contractor in conducting the initial customer survey.

The project was conducted in two phases. The first phase developed an initial customer group identification methodology, and assessed two survey instruments used to query these customers on their assessment of DLA products and services. The second phase used results from these surveys to develop a final customer identification methodology and recurring sampling plan.

1.2 PURPOSE

The purpose of this project was to further segment the customer groups defined by project DLA-93-P20355, incorporating new data on the fuels and subsistence commodities. The development of a customer sampling plan and customer address information base was also requested to support the ICP Corporate Customer Assessment Team survey of DLA customers.

1.3 OBJECTIVES

The general objectives of this study were to:

(1) Further develop the stratification of customers based on the 1992 customer information files, updated with subsistence data provided by the Defense Personnel Support Center (DPSC) and fuels data provided by the Defense Fuel Supply Center (DFSC). This base would support the initial customer stratification and survey instrument assessment.

(2) Review Department of Defense Activity Address Code (DoDAAC) assignment methods used by the Services, to determine their suitability in identifying customer types.

(3) Define customer groups by combinations of commodity, Service or agency and type of activity (e.g., medical activities, repair facilities, etc.) based on DoDAAC structure.

(4) Establish a sample size and select a sample of customers for each customer group identified, based on a target statistical confidence level.

(7) Provide CAIC a mailing list containing DoDAACs, addresses, annual dollar value of requisitions and control numbers for all customers identified, using FY 1992 data.

(8) Provide CAIC two representative sample sets of 250 customers each, to be used in testing the surveys.

(9) Analyze the sample survey returns to assess required changes to the customer stratification methodology and sampling plan.

(10) Upon final approval of the stratification methodology, provide a final customer information base containing DoDAACs, addresses, annual dollar value of requisitions, and volume of requisitions for all customers identified, using the latest fiscal year data available.

1.4 SCOPE

Only data resident in DORO, DPSC, DFSC and a Defense Automatic Addressing System Center (DAASC) DoDAAC cross reference file were employed.

The mailing list was to be developed for use in dBase III+, to include DoDAACs, addresses, control numbers identifying the customer by commodity, Service or agency, type of activity, requisition volume and dollar volume of customer requisitions.

Internal DLA customers (DLA Depots, Centers, et cetera) identified by the previous DORO project were excluded from final sample plan development at the request of CAIC.

1.5 EXCEPTIONS

DLA Integrated Data Bank (DIDB) information on the fuels and subsistence commodities was not adequate for the project. Fiscal year 1992 and fiscal year 1994 data on these commodities were provided by DFSC and DPSC.

The methods for assignment of DoDAACs by the armed services was inconsistent. This precluded a uniform identification of customers by activity type.

SECTION 2

METHODOLOGY

2.1 PHASE ONE: INITIAL CUSTOMER STRATIFICATION

The first question faced by the Corporate Customer Assessment Team was the appropriate definition of a customer. Options included personnel responsible for ordering DLA items, maintenance personnel relying on equipment and parts from DLA, and "warfighters" who expect the required equipment to be fully operational in order to complete their missions. The team concluded that the logisticians, supply personnel who order from DLA and conduct follow-up shipment status tracking, were the customers most directly affected by DLA. They in turn influenced the perception of others at their commands. Based on this decision, surveys would be mailed to the logisticians at each activity.

The second issue was the matter of identifying individual customers, and establishing customer strata in which customers with similar characteristics were grouped together. The previous DORO study identified customers by commodity and major Service or agency. As recommended in that report, these groups were further segmented to identify the customer by specific activity type. Support for further segmentation came from the Corporate Customer Assessment Team and the contracted survey provider, with the goal of establishing as many identifiable customer groups as possible. The key was to develop customer groups having unique attributes or logistics requirements, such as medical facilities or repair facilities.

As described in the earlier study, the DoDAAC provides the only consistent identification of DLA customers across all ICPs, depots and customer service offices. Reviews were conducted of the DoDAAC assignment methodology employed by the various Services to determine a suitable system of customer segmentation. While not completely successful, stratification based on DoDAAC did prove useful. Because the Services differ in their assignment methods, each Service was segmented differently.

2.1.1 AIR FORCE CUSTOMERS

The Air Force applies a fixed and organized DoDAAC assignment methodology to their units, making this group the most easily stratified by activity type. Air Force customers were segmented using the first two positions of the DoDAAC, in accordance with reference (a), Air Force Manual 67-1. Twenty-five activity types were identified by this method. Contractors identified by the Air Force publication were included in a separate contractor group. The Air Force activity types are listed in Appendix A.

2.1.2 NAVY CUSTOMERS

Navy DoDAAC assignment is not as structured as the Air Force, providing only very broad stratification of units by type of activity. Navy customers were initially segmented by DoDAAC in accordance with reference (b), the Navy Comptroller Manual. Further refinement was

conducted using key word sorts on the unit names, such as "aviation", "supply", or "USS". The fifteen Navy customer activity types are listed in Appendix A.

2.1.3 FEDERAL AGENCY CUSTOMERS

The Federal agencies group was easily stratified into individual agencies using the first two positions of the DoDAAC in accordance with reference (c), DLA Manual 4140.2. Seventy-seven customer activity types were identified, 40 of which requisitioned materiel from DLA in fiscal year 1992. These 40 are listed in Appendix A.

2.1.4 CONTRACTORS AND FOREIGN MILITARY SALES

Both the Contractor group and the Foreign Military Sales (FMS) group were segmented by identifying the sponsoring Service (e.g., Navy contractor, Army FMS). The first position of the DoDAAC was used to make the identifications. This gave each group five activity types, as listed in Appendix A.

2.1.5 NON-SEGMENTED CUSTOMER GROUPS

Army, Marine Corps and Coast Guard customer groups were not segmented by activity type. Extensive review of these Services' instructions (references (d) through (f)) and consultations with representatives at their DoDAAC central service points determined that no systems were in place to assign DoDAACs based on activity type. Attempts to conduct key word sorts on unit names were unsuccessful, as were attempts to cross-reference these DoDAACs to other identification-type files such as the Army's Table of Organization and Equipment.

2.1.6 CUSTOMER ADDRESS INFORMATION

Customer addresses were first developed by matching the DoDAACs to the customer address file resident in the DIDB. DoDAACs which did not have address information in the DIDB were then matched against a customer address file provided by Defense Automatic Addressing System Center.

A dBase III+ data file was created to provide mailing information for the customer surveys. This file, as delivered to CAIC, included DoDAAC, four-line mailing address, customer control code and dollar value of requisitions for each of the 31,991 customers identified. A description of the data fields is included as Appendix B.

2.2 INITIAL SAMPLING PLAN

Statistical sampling plans are designed to allow inferences to be drawn about a population by testing a representative group from that population. A primary requirement for such plans is that the members of the population have similar characteristics. The segmentation of customers as described in Section 2.1 could not meet that requirement. In some cases, the population under consideration was an entire major Service, such as the Army, while in other cases the population was a very specific subset of a Service, such as Navy medical activities. Further, without some

a priori knowledge of customer satisfaction, the statistics required to objectively compute sample sizes were not available, in that such calculations require knowledge of the expected variance from the average response in each group.

DORO analysts met with the CAIC representative and the contractor developing the customer survey instrument to determine the desired method of sampling the various groups. At the contractor's recommendation, CAIC requested that DORO construct a customer address data base that would support a "baseline" survey, that is, all fiscal year 1992 customers would be surveyed.

The Corporate Customer Assessment Team also required customer responses be linked to specific ICPs, rather than their perception of DLA in general. This information would assist in identifying strengths and problems at individual ICPs, allowing tailored responses at each site to improve customer satisfaction. The survey instrument was therefore planned to be commodity-specific, and a random selection process was used to prevent a customer who had purchased several types of commodities from receiving multiple surveys. A customer who purchased only one type of commodity was placed in the group receiving that commodity's survey. If a customer ordered several commodity types, one of those commodities was randomly selected, and the customer was placed in that survey group. This random selection process was chosen as the most appropriate method to ensure that both high and low-volume customers for each commodity were fairly represented in the survey.

2.3 CUSTOMER CONTROL NUMBERS

Customer control numbers were developed to identify the survey participants by commodity purchased, major Service or agency, and type of activity. A 4-digit code was assigned to each customer. The first digit indicated the commodity on which the customer was surveyed. The second digit indicated major Service or agency. These code positions were defined as follows:

<u>1st Digit</u>	<u>2nd Digit</u>
1 = Construction	1 = Army
2 = Electronics	2 = Air Force
3 = Fuels	3 = Coast Guard
4 = General	4 = Marine Corps
5 = Industrial	5 = Navy
6 = Medical	6 = Foreign Military Sales
7 = Subsistence	7 = Contractors
8 = Textiles	8 = Federal Agencies

Figure 2-1. Commodity and Agency Codes

The 3rd and 4th digits specified the activity types, which can be identified using the listings in Appendix A. An example of the control code:

Figure 2-2. Customer Control Code

Based on the eight DLA commodities, eight major services or agencies, and the activity types listed in Appendix A, a total set of 744 survey groups was developed. A total of 31,991 customers were assigned to the 744 cells. An additional 1,582 customers (approximately 1% of the total customer base) did not have addresses available in either the DAASC or DIDB address files, and were not included in the survey groups. These were primarily FMS customers. Appendix C details the number of customers in each survey group.

2.4 SAMPLE SURVEYS

The Corporate Customer Assessment Team was considering two survey instruments, the "Gap model" and the "Attitude model". The Gap model attempts to measure the difference between the level of service the customer expects and the level he receives. In essence, if a customer's expectations are low, then lower quality service may be acceptable. Conversely, high expectations create a challenge to deliver only superior service. The Attitude model measures the customer's perception of performance without regard to expectation. It provides a direct expression of the customer's perception of DLA, as he is free to compare the service to any other experiences he has had. The yardstick may vary from customer to customer, but the overall picture is useful in identifying strong and weak areas in DLA's performance. A small preliminary mailing was planned in which one set of customers would receive the Gap model survey, while another set received the Attitude model survey.

2.4.1 CUSTOMER SELECTION

In order to select the most useful survey, CAIC requested two sample sets, of 250 customers each, to conduct the preliminary survey. Customers were to have had requisitions of at least \$1000.00, in order to maximize the information obtained from these small samples. The sample should otherwise be representative of the overall customer population. In selecting the sample customers, the following procedures were applied:

- Each Service or agency received at least eight surveys, in order to test across all commodities. The only exception to this was the Marine Corps, who had no Fuels customers.

- Remaining surveys were distributed proportionately among the Services and agencies. For example, federal agencies represented approximately 7% of DLA's customers, and so received 7% of the surveys.
- Surveys for a given Service were distributed proportionately among the Service's activity types.
- A random number generator was used to select specific customers within each activity type.

The final customer samples were:

Army	-----	157
Air Force	-----	8
Coast Guard	-----	8
Marine Corps	-----	7
Navy	-----	27
Contractors	-----	8
Federal agencies	-----	35
		250

Figure 2-3. Sample Survey Customers

2.4.2 SAMPLE SURVEY ANALYSIS

Primary analysis on the sample survey returns was conducted by the CAIC contractor, with additional statistical examination performed by DORO. The contractor provided results to CAIC, independent of the DORO analysis. While the contractor's report focused on the validity of individual questions and assessed the customer's perception of DLA, DORO's effort was dedicated to developing the statistics required for sample size computations.

Statistics were developed for the seven "overall opinion" questions of the surveys, items 105 through 111. These questions were selected for in-depth analysis for several reasons. First, the design of these questions lends itself to numerical analysis; that is, the answers range from 1 to 5, with 1 being the most negative and 5 the most positive response in every case. Second, these questions do not rely heavily on detailed or esoteric knowledge. They are well phrased, without confusing language or key words, and they make no assumption about the level of expertise of the respondent. Finally, these questions measure overall satisfaction, attitudes, expectations, and whether or not DLA is seen as a problem source. Complete statistics on the sample surveys are contained in Appendix D. The most important findings were that customer perception of DLA was reasonably favorable, with most respondents reporting average or higher service quality. Individual customer responses varied only slightly from the mean.

2.4.3

SAMPLE SIZE METHODOLOGY

Based on these statistics, sample size calculations were conducted. DORO considered several methods of determining an optimal sampling plan. In most logistics studies, a simple, non-stratified population of items is under consideration, from which a set is drawn for testing or evaluation. A typical example is a delivery of bolts, some portion of which are examined to ensure they meet the standards prescribed for strength, diameter, et cetera. Standard procedures for such quality control efforts are readily available, such as Mil. Std. 105D, *Sampling Procedures and Tables for Inspection by Attributes*. Customer sampling plans, however, involve several issues that are not considered by such procedures.

The initial problem is that presented by stratification. In relatively large and homogeneous populations, a reasonably small sample can adequately represent the overall population. When this population is stratified, however, some strata may be only lightly populated, and a greater proportion of the strata may be required to develop accurate statistics. An extreme example would have an overall population of 1,000 from which a sample of 20 (or 2% of the total group) is drawn, sufficient for accurate analysis. If the population is stratified into 10 groups of 100, and the same proportion applied to sample selection, only 2 members of a stratum would be used to predict the overall behavior of their 98 partners. If by chance one or both of those selected are atypical of the rest of the group, the results of analysis are unusable. In considering this issue, one source suggests that a sample should provide 100 or more units in each major category, with a minimum of 20-50 in minor categories.¹ In our final stratification plan, all customers of a specific ICP may be considered a major category, while members of a single Service or Agency within that group would be a minor category. While a sampling plan cannot rely solely on such generalizations, they are useful when used in conjunction with other methodologies.

A second issue is that of sample bias. If a sample is not truly representative of the overall population, the results of analysis will be unreliable. Bias can result from a poorly designed sampling plan, or poor execution of a sampling plan. In the first case, it is important that the sample drawn be truly random. Many studies apply *systematic sampling* techniques, which can adversely affect the selection process. The simplest process would be starting at the top of a list of members, pulling off names until the desired sample size is reached. A more common type of systematic sampling involves selecting a random number n to use as a starting point (for example, the number 8), and every n^{th} member of the group is drawn (every 8th member, in our case). In a randomly arranged list of candidates, either process can successfully provide the required sample. Now consider a list of all Air Force customers, sorted by DoDAAC, from which we want eight members. As described earlier, the Air Force uses the DoDAAC to identify the type of activity. Using the first method would result in eight Accounting and Disbursing Stations, obviously not representative of the Air Force as a whole. Applying the second method raises the possibility that a small group may be completely unrepresented, if the selection interval is larger than the stratum size.

¹ Sudman, Seymour. *"Applied Sampling."* Handbook of Survey Research, 1983 New York: Academic Press.

In random sampling, the probability of selection of any particular member is equal throughout the stratum. If a sample of eight is desired from a group of 50, then eight random numbers between 1 and 50 are generated and corresponding members drawn from the population. Each member then has an equal chance of selection. In our example, while Accounting and Disbursing Stations may be a small subset of Air Force customers, they will not be systematically excluded by the selection process, and will in fact be chosen in proportion to their representation among all Air Force customers. If recurring samples are conducted as planned, each such set of specific customers will be "fairly" represented in the overall analysis. This process was applied in selecting the sample survey participants.

Finally, bias in survey execution can affect the final analysis. Customers chosen for survey may decline to respond. One result of this is "non-response bias", where the results of the analysis are skewed to represent that part of the sample that chose to respond. In sampling studies, it has been seen that factors such as age, economic background, or educational level affect whether a person will answer a survey. In our case, the Customer Assessment Team selected a very specific type of respondent, the logistics representative at each customer activity. This decision can be expected to reduce non-response bias based on many external factors. Some problems remain, in that customers experiencing the most difficulty with DLA services may be more inclined to respond, seeing an avenue to improve DLA support. Others may regard the survey as unimportant, and simply not take the time to return it. The most important tool in reducing non-response bias is survey follow-up, using second mailings or telephone contact to ensure the maximum number of surveys are completed and returned.

An unfortunate consideration in selecting sample size is the expense of executing the survey. Each observation has an associated cost. If the sample size is too large, time and money are wasted in collecting information. Conversely, if the sample is too small, then the data is inadequate for accurate assessments, and again resources are wasted. While cost cannot be allowed to control the sample size determination, it is a factor to be considered in developing the sampling plan. DLA's baseline survey provided valuable data that will allow future samples to be much smaller and less costly.

Keeping this in mind, the following formula was applied to determine the smallest samples necessary to accurately evaluate DLA's performance as perceived by the Agency's customers²:

$$\text{Sample Size} = \frac{N \times s^2}{(N-1) \times \left(\frac{\text{Error}}{\text{Confidence Interval}} \right)^2 + s^2}$$

N represents the total population, used in our calculations as the population in a given strata (for example, Army customers buying General commodities). $N-1$, used in the denominator, has particular consequence when the denominator is small. The factor s^2 is in fact the sample variance from the survey responses. This factor yields a very good estimate of total population variance. The *Error* factor is chosen to achieve a reasonably sized sample while maintaining an accurate estimation of the true population response. DORO used an Error factor of 0.1 throughout the calculations; if the sample population's mean response equals 4.0, we will accept

² Schaeffer, Richard L. Elementary Survey Sampling, 1990 Boston: PWS-Kent.

that the total population's response is between 3.9 and 4.1. Finally, a confidence interval yielding 95% certainty was applied. We are then 95% certain that the sample population mean is within 0.1 of the total population mean.

This formula addresses many of the issues previously discussed. By using a separate N for each stratum population, we ensure that a sufficient sample is drawn from each stratum. This precludes problems that arise from calculating a sample from the total population and applying it to subordinate strata. The Error factor can be manipulated to reduce sample sizes to cut survey costs, within the constraints of maintaining an accurate assessment. The chosen Error factor of 0.1 achieves both of these goals. Finally, the formula does not rely on some "judgment factor" of how large a sample should be. Given the variance data of the earlier surveys, sample sizes can be calculated objectively for each stratum. Future surveys will provide additional data for the calculation of variance, from which new sample sizes may be generated.

2.4.4 SAMPLE SURVEY CONCLUSIONS

The similarity of responses across customer groups indicated that the number of strata could be significantly reduced. DORO recommended a total of 15 customer groups. Six Inventory Control Points were consolidated, leaving only the Fuel and Medical ICPs individually identified. This resulted from the statistical agreement among customers of the six "hardware" ICPs, and the practical issue that Fuels and Medical commodities have significantly different customer bases, procedures and logistics requirements than the other commodities. Military Services were also restructured into a single group, as no significant differences in their responses were detected during analysis. The same was true for the individual Federal Agencies who responded. Table 2-4 identifies the proposed groups as well the number of customers in each group, based on the FY 1992 customer data.

Strata	Hardware	Fuel	Medical
Contractor	499	26	53
DoD	731	0	24
Federal Agencies	3,071	26	1,056
FMS	1,468	0	209
Military Services	26,003	733	8,282
Total	31,772	785	9,624

Figure 2-4. Proposed Customer Segmentation: Number of Customers in Each Strata

The greatest advantage to this segmentation plan was that the number of surveys required to develop an accurate assessment of customer satisfaction was very small. By applying the sample size formula previously described, it was determined that only 1636 responses would be necessary, greatly reducing the cost of conducting future surveys.

Strata	Hardware	Fuel	Medical
Contractor	146	23	42
DoD	161	0	22
Federal Agencies	194	23	173
FMS	181	0	104
Military Services	205	161	201
Total	887	207	542

Figure 2-5. Proposed Customer Sampling Plan: Number of Surveys in Each Strata

The proposed customer segmentation plan was briefed to CAIC on 4 August 1994. An alternative scheme maintaining the military Service identity of customers was also provided. While recognizing the advantages of each plan, CAIC had a requirement to track customer responses to specific Inventory Control Points, as well as maintain the separate identity of each service. DORO agreed to develop a sampling plan based on these requirements, using results from the baseline survey. It was expected that the additional information from those customer responses would allow more accurate sample size computations.

The low response rate to the sample survey precluded an objective selection regarding which model to use in future surveys. As previously described, 250 customers received surveys based on the Attitude model, while 250 received surveys based on the Gap model. A total of 58 responses were received from the Attitude model surveys, while 36 were received from the Gap model surveys. Greater statistical validity accrued to the Attitude model results, based solely on having more responses to evaluate.

Finally, DORO recommended a shortened questionnaire to encourage responses by customers. Both the Gap model and Attitude model questionnaires were quite lengthy. It is likely that some customers declined to respond based solely on the amount of information they were being asked to provide. Research in the customer sampling field has shown that short, easily answered surveys have a higher response rate than comprehensive questionnaires.

2.5 PHASE TWO: FINAL CUSTOMER STRATIFICATION

The baseline survey entailed mailings to 26,920 DLA customers, of which 5,531 were returned. Again, primary analysis was conducted by the CAIC contractor, with additional statistical examination performed by DORO. The response rate, while only slightly above 20%, did provide additional data which enabled DORO to more precisely calculate sample sizes for future surveys. Additionally, this survey would provide greater information on the variability of responses between the customer groups, ensuring that the final customer stratification plan properly identified all uniquely identifiable groups.

2.5.1 BASELINE SURVEY ANALYSIS

Overall, analysis of the responses to the baseline survey indicated that customers maintain a very positive view of DLA. The survey instrument was revised based on the results of the sample survey, leaving five "overall opinion" questions for analysis (items 76-80). In every case 90% of respondents answered with 3 (Average Performance) or higher. More important to the DORO effort, individual customers responses again varied only slightly from the average response in each group, indicating that small samples from a few well-defined customer strata would provide an accurate assessment of customer satisfaction. Baseline survey statistics are provided at Appendix E.

2.5.2 BASELINE SURVEY CONCLUSIONS

Based on the baseline survey responses, the requirements for individual ICP and military Service visibility, and the constraints of the Services' DoDAAC assignment methodology, the final customer stratification scheme was developed. A total of 72 customer strata allow a comprehensive view of DLA performance while providing individual analysis for specific ICPs and military Services. Figure 2-6 presents the final strata development:

Customer Types	Commodity Groups
Army	Construction
Air Force	Electronics
Navy	Fuels
Marine Corps	General
Coast Guard	Industrial
Federal Agencies	Medical
Contractors	Subsistence
Foreign Military Sales	Textiles
DLA	

Figure 2-6. Final Customer Groups

Sample size calculations were conducted on these new strata, applying the formula from Section 2.4.3 and the statistical variance developed from the baseline survey. DLA activities were not included in the final calculations, as they represent internal Agency transfers rather than true customers. This reduced the number of strata from 72 to 64. The resulting sample consisted of 9,720 customers from the overall population of 32,415 non-DLA activities. The final sampling plan is presented in Section 3, Results.

2.5.3

CUSTOMER INFORMATION BASE UPDATE

The customer information base for both the sample and baseline survey was based on requisitions from fiscal year 1992. Discussions regarding updates to the information base centered on frequency of update, alternative sources of data, responsibility for continuing maintenance, and additional customer identification methodology.

In discussions with CAIC, it was decided that the update should be conducted after final analysis of the baseline survey, when the final customer stratification strategy would be developed. Any update prior to that determination would not add any useful information to the effort, and would require modification later to fit the final stratification scheme.

An additional issue regarding customer identification arose during the course of the project. There are activities which receive shipments from DLA depots, while not requisitioning directly from DLA. Because the customer information base was developed from requisition history files, these "distribution customers" were not included. While DORO did investigate methods of identifying these customers, they were not included in the updated customer information base. Further examination by the Corporate Customer Assessment Team should be conducted before including these activities in future data bases.

Finally, CAIC requested additional fields in the information base to identify the state in which the activity resides, and the dollar value of the requisitions submitted during the fiscal year. State information was drawn from the "mail state" field of the requisition history files. Dollar value calculations were conducted in developing the original information base, and were now added to the final data file.

The final customer information base was developed using fiscal year 1994 requisition history files, the latest complete fiscal year for which data was available. The new stratification methodology obviated the need for identification by type of activity within each service, greatly reducing processing time. The customer control numbers discussed in Section 2.3 were no longer required, and were replaced with simpler identification by Service (USAF, USMC, etc.). Customer addresses were drawn from the DIDB customer address file; due to the marginal value of running a second match against the DAASC address file, the step was omitted for the update. The updated customer information base was delivered to CAIC as a dBase III+ file.

SECTION 3

RESULTS

3.1 CUSTOMER INFORMATION BASE

The updated customer information base identified 32,943 customers, submitting 19,342,064 requisitions having a total value of \$14,982,749,210. The fuel commodity, while having the fewest requisitions of any ICP (only 1/2 of one percent of total requisitions submitted), accounted for almost 43% of sales volume. This results from a small number of fuel sites purchasing the relatively expensive fuel commodities in great volume. The medical commodity had the lowest dollar sales, totaling only \$539,232,963. Overall, these totals do not significantly differ from those found in the fiscal year 1992 data.

Figure 3-1. Comparison of Sales by Inventory Control Points

The inclusion of the Mail State field provided only marginal return. Almost without exception, customers with APO or FPO addresses did not provide data in this field. Many other customers entered State information in the free-format address fields, using the full state name or a variety of abbreviations, precluding successful text searches within those fields. Accordingly, the ZIP code provides the most reliable method of geographic data on the customers.

The final file layout was a 305-column flat file, sorted by DoDAAC, providing customer DoDAAC, Service, mail state, ZIP code, address, and requisition volume and dollar value for each separate commodity. The final customer information base file layout is provided at Appendix F.

3.2

CUSTOMER STRATIFICATION

Figure 3-2 presents the number of customers by Service for fiscal year 1994. One customer DoDAAC could not be associated to a specific service, as the Service identifier may be used by all Services (DoDAAC YDFSPM, a Fuels customer). DLA customers are included for information only; as previously discussed, these are primarily inter-depot transfers to maintain stock levels, and should not be included in customer satisfaction surveys.

Figure 3-2. Customers by Service or Agency

As the chart indicates, Army units account for great majority of individual customers. This is in consonance with other DORO studies, and results from the Army's system of assigning DoDAACs to relatively small units. This allows flexibility in reorganizing units to various larger commands without interrupting their logistics support. Conversely, the relatively small number of Air Force customers reflects the Air Force practice of consolidating requisitions from smaller units before forwarding them to DLA.

Figure 3-3 presents the number of customers in each strata. This stratification table is the basis for customer sampling plan calculations. It should be noted that a customer requisitioning more than one commodity in 1994 will appear in more than one cell in the stratification table.

	Cons	Elex	Fuel	Genl	Indl	Medl	Subs	Text	Total by Service

Figure 3-3. Customer Stratification Table

3.3 CUSTOMER SAMPLING PLAN

The sampling plan methodology discussed in Section 2.4.3 was applied to the customer strata of table 3-3. Sample sizes were calculated using the prescribed formula and statistics developed from the baseline survey. DLA activities were excluded, resulting in 64 customer strata. The final sample sizes are presented in figure 3-4.

	Cons	Elex	Fuel	Genl	Indl	Medl	Subs	Text	Total by Service
Army	191	190	90	191	191	186	126	190	1,355

Total by ICP	1,431	1,458	597	1,504	1,433	1,217	759	1,321	9,720

Figure 3-4. Sample Size by Customer Strata

These sample sizes provide the smallest number of responses required to develop an assessment of customer satisfaction with a 95% confidence level. The number of surveys actually mailed is dependent on the expected response rate of the customers.

3.4 ADDITIONAL CUSTOMER IDENTIFICATION

As previously, mentioned, CAIC requested a feasibility assessment of including "distribution customers" in the customer information base. These customers can be identified using the DIDB MRO files, which show shipments from DLA depots. These records, then, identify all activities served by DLA depots, regardless of the agency to which the requisition was made. This file appears suitable for identifying DLA's "distribution customers".

Two considerations arise in application of these files. First, the Corporate Customer Assessment Team defined a DLA customer as the activity submitting the original requisition to DLA, which led to the use of the DIDB requisition history files to identify customers. Some activities identified by MRO files do not meet this definition. Shipments from DLA depots may be in response to requisitions for items managed by non-DLA agencies, using DLA storage assets for purposes of economy or advantageous location. Second, an important feature of the customer information base is the ability to rank customers by the number of requisitions submitted, and the dollar value of requisitions submitted. This information for distribution customers actually accrues to the agency managing the items ordered; if not carefully manipulated, quantity and cost information on these activities will inflate the calculation of DLA sales volume.

Neither of these issues preclude inclusion of distribution customers in the customer data base. The Corporate Customer Assessment Team does need to weigh these considerations in determining the desirability of redefining the term "customer" as it applies to the Agency.

SECTION 4

RECOMMENDATIONS

4.1 SURVEY RECOMMENDATIONS

Analysis of the sample survey and baseline survey indicate several issues to consider in conducting recurring surveys.

4.1.1 SAMPLING PLAN

DORO recommends implementation of the sampling plan provided by Figure 3-4. Again, these values indicate the minimum number of *returned surveys* required to achieve an accurate assessment of customer satisfaction. Calculations for the number of actual mailings must reflect the expected response rate to the survey. For example, if the 20% response rate seen in the initial surveys persists in future surveys, 48,600 mailings would be required to achieve the 9,720 required returns shown by Figure 3-4. With only 32,943 customers available, this response rate obviously cannot provide the required returns to calculate customer satisfaction to the levels desired. Improving the response rate to 40% would reduce the required mailings to 24,300.

Samples should be taken without replacement, that is, once a customer has been selected to receive a survey, he cannot be chosen again. The customer counts in Figure 3-3 show customer totals by commodity; a single customer requisitioning multiple commodities will appear in more than one cell. This method ensures visibility of customers to management at each ICP, as requested by CAIC. Sampling without replacement will ensure no customers receive more than one survey; given the large customer base, each strata is sufficiently populated to provide random selection using this method.

4.1.2 SURVEY FOLLOW-UP

The response rates of both the sample survey and baseline survey were very low, approximately 20% for the larger survey. While the contracted survey developer states that this is normal for a single-mailing survey with no follow-up¹, it must nevertheless be considered when deciding how many surveys to be mailed. Actions to increase the response rate should be considered in order to minimize the costs of conducting future surveys.

DORO recommends initial mailings be carefully tracked for response by the requested deadline date. Follow-up mailings or telephone contact on unreturned surveys should be considered, both to improve response rate and to ensure customers of DLA's commitment to meeting their needs. A 50% response rate seems an achievable goal that will reduce the number of mailings required without creating an undue administrative burden dedicated to tracing all non-responses.

¹ John T. Mentzer, University of Tennessee, Knoxville

Finally, alternative survey methods should be considered, including electronic surveys, telephonic surveys, and questionnaires shipped with deliveries. Any of these methods may increase survey response, and in some cases target specific customer groups that may have particular issues requiring resolution.

4.1.3 SURVEY CONTENT

The complexity of the initial surveys may have contributed to the low response rate. DORO recommends that the questionnaire be modified to contain fewer questions, with less detailed information requested. A few well-worded questions can provide an assessment of customer satisfaction, and identify any important trends which may deserve further investigation.

4.2 CUSTOMER INFORMATION BASE RECOMMENDATIONS

CAIC requested specific recommendations on maintenance of the customer information base, including frequency of update and alternative sources of data.

4.2.1 UPDATE FREQUENCY

The customer information base should be updated annually, on a fiscal year basis. This periodicity provides reasonable visibility of new customers, lost customers, and changes to unit addresses (particularly for military customers with shifting APOs), while minimizing data collection and processing costs.

4.2.2 DATA SOURCES

While DORO maintains the capability to update the customer information base, we recommend that recurring updates be provided by the Defense Automatic Addressing System Center (DAASC). As described in Section 2.1.6, the initial customer information base was supported by a customer address file provided by DAASC. DAASC has visibility of supply transactions for all customers ordering from the Defense Logistics Agency, thereby establishing the capability to provide requisition counts, dollar value and address information for every DoDAAC doing business with the Agency. This sole source of information can replace the multiple sources DORO utilized in developing the original files. This also precludes the need for data calls to DPSC and DFSC to supplement the DIDB requisition history data, and ensures that data format and content is consistent across all commodities.

Alternatively, data can be provided individually by each ICP. While this would require Headquarters DLA to manage file format and content, it provides the benefit of ensuring agreement between Headquarters and each ICP. In efforts of this type, discrepancies frequently arise when separate offices include different record types in their data manipulation. By setting a prescribed format, DLA Headquarters would ensure consistency while keeping the ICPs involved in the overall effort.

4.2.3

DISTRIBUTION CUSTOMERS

DORO recommends maintaining a separate data file on distribution customers, primarily due to the different nature of their requirements. Because they do not order directly from DLA, it can be expected that their perception of logistics support is influenced primarily by their supporting organizations, rather than DLA. Further, the measure of interaction for this group is likely the total number of shipments made, rather than requisitions submitted or dollar value of sales. A separate survey instrument may also be appropriate to ensure that management receives an accurate assessment of customer satisfaction from this group.

APPENDIX A
ACTIVITY CODES BY SERVICE

Activity Codes By Service

Discussion

Section 2.3 describes the assignment of customer control numbers to identify the survey participants by commodity purchased, major Service or Agency, and type of activity. A 4-digit code was assigned to each customer in the original FY92 customer information base.. The 3rd and 4th digits identify the activity types.

Air Force Activity Codes

Activity Code	Activity Type
00	Accounting and Disbursing Station Number
01	Administrative Reporting

13. ABSTRACT (Maximum 200 words) This project developed a plan for conducting recurring surveys of Defense Logistics Agency customers, in support of the DLA Corporate Customer Assessment Team. The primary product was a sampling plan, including stratification of customers by Military Service or Federal Agency and by commodity purchased from DLA, and sample size calculations for each stratum. The secondary product was a customer data base, identifying customers by activity name, major Service or Agency, mailing address, and Department of Defense Activity Address Code (DoDAAC). Number of requisitions submitted and the dollar value of those requisitions are included for each customer, for each commodity, using fiscal year 1994 data. While the data base was initially developed to provide required address information for mailing customer satisfaction surveys, it is very useful in examining requisition data on individual customers and groups of specific customer types, both within and across individual Inventory Control Points.
