DTIC QUALITY INSPECTED 5

The Mission of AGARD

According to its Charter, the mission of AGARD is to bring together the leading personalities of the NATO nations in the fields of science and technology relating to aerospace for the following purposes:

- Recommending effective ways for the member nations to use their research and development capabilities for the common benefit of the NATO community;
- Providing scientific and technical advice and assistance to the Military Committee in the field of aerospace research and development (with particular regard to its military application);
- Continuously stimulating advances in the aerospace sciences relevant to strengthening the common defence posture;
- Improving the co-operation among member nations in aerospace research and development;
- Exchange of scientific and technical information;
- Providing assistance to member nations for the purpose of increasing their scientific and technical potential;
- Rendering scientific and technical assistance, as requested, to other NATO bodies and to member nations in connection with research and development problems in the aerospace field.

The highest authority within AGARD is the National Delegates Board consisting of officially appointed senior representatives from each member nation. The mission of AGARD is carried out through the Panels which are composed of experts appointed by the National Delegates, the Consultant and Exchange Programme and the Aerospace Applications Studies Programme. The results of AGARD work are reported to the member nations and the NATO Authorities through the AGARD series of publications of which this is one.

Participation in AGARD activities is by invitation only and is normally limited to citizens of the NATO nations.

The content of this publication has been reproduced
directly from material supplied by AGARD or the authors.

Preface

This volume provides abstracts and indexes for AGARD unclassified publications during the period 1992-1994. By an arrangement with U.S. National Aeronautics and Space Administration (NASA) in Washington, DC, the computerized NASA STI Database has been used to prepare this publication.

Full bibliographic citations and abstracts for all the documents in this publication are given in the abstract section, which is organized in the major subject divisions and specific categories used by NASA in abstract journals and bibliographies. The major subject divisions are listed, together with a note for each that defines its scope and provides any cross-references. Category breaks in the abstract section are identified by category number and title, and a scope note. Within each category, the abstracts are arranged by series and year.

Six indexes — Subject (based on *NASA Thesaurus nomenclature*), Personal Author, Corporate Source, Panel, Report/Accession Number, and Accession Number — are included. Sample entries are shown on the first page of each index.

Details of AGARD's classified publications for the same period are contained in a companion, classified, index.

Préface

Ce volume contient des résumés et des indexes relatifs aux publications non-classifiées de l'AGARD parues entre 1992 et 1994. Selon l'accord qui existe entre l'AGARD et l'US National Aeronautics and Space Administration (NASA) à Washington DC, la base de données informatisée STI de la NASA a été utilisée pour la préparation de la présente publication.

Des résumés et des citations détaillées relatifs à tous les documents figurant dans cette publication sont inclus dans la section résumés de l'ouvrage, qui est organisée selon les domaines et les catégories spécifiques employés par la NASA dans ses recueils de résumés et ses bibliographies. Les domaines principaux sont énumérés, avec une note pour chacun d'entre eux, définissant son contenu et indiquant d'éventuels renvois. Les changements de catégories au sein de la section résumés sont identifiés par un numéro de catégorie, un titre et une note de contenu. Les résumés sont classés par série et par année à l'intérieur de chaque catégorie.

Six indexes en tout sont presentés, à savoir, Matière (selon la nomenclature du Thesaurus de la NASA), Auteur individuel, Source collective, Panel, Numéro de rapport/Numéro d'acquisition, et Numéro d'acquisition. Des exemples d'entrées sont donnés à la première page de chaque index.

Le détail des publications classifiées de l'AGARD pour la même période est donné dans un autre index, classifié, dans la même série.

SUBJECT CATEGORIES

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) 1

02 AERODYNAMICS 2
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY 30
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION 37
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE 47
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION 72
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER 78
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL 104
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) 111
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) 118
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS ..... N.A.
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) ..... N.A.
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES 118
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION 119
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING ..... N.A.
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **119**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance*, *39 Structural Mechanics*, and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION **122**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **123**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power*, *28 Propellants and Fuels*, *44 Energy Production and Conversion*, and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) ..... **N.A.**

24 COMPOSITE MATERIALS **125**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **138**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **143**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **144**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **147**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power*, *20 Spacecraft Propulsion and Power*, and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **148**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **149**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **152**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **184**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **186**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **219**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **221**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING **223**
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY **224**
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS **226**
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) ..... **N.A.**

43 EARTH RESOURCES AND REMOTE SENSING **229**
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION ..... **N.A.**
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION **229**
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS **230**
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY **233**
Includes weather forecasting and modification.

48 OCEANOGRAPHY ..... **N.A.**
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) **234**

52 AEROSPACE MEDICINE **234**
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES **259**
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT **261**
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY ..... **N.A.**
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) ..... **N.A.**

60 COMPUTER OPERATIONS AND HARDWARE **282**
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE **282**
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS **288**
Includes computer networks and special application computer systems.

63 CYBERNETICS **288**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **291**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **291**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **292**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS ..... **N.A.**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **296**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS **296**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS ..... **N.A.**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS ..... **N.A.**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **304**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS ..... **N.A.**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS ..... **N.A.**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **307**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) ..... **N.A.**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **308**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **308**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS ..... **N.A.**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY ..... **N.A.**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION ..... **N.A.**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) ..... **N.A.**

89 ASTRONOMY ..... **N.A.**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS ..... **N.A.**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION ..... **N.A.**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS ..... **N.A.**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION ..... **N.A.**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

ABSTRACT → The transitional flight characteristics of a geometrically simplified Short Take-Off Vertical Landing (STOVL) aircraft configuration were measured in the NASA Ames 7- by 10-Foot Wind Tunnel. The experiment was designed to provide detailed data for evaluating the capability of computational fluid dynamics methods to predict the important powered lift flow parameters. The model consists of a 60 deg cropped delta wing planform; a blended fuselage; and tandem, circular, high pressure air jets that exit perpendicular to the flat lower surface. Freestream Mach number is limited to a maximum 0.2. Model angle of attack ranges from -10 deg to +20 deg. The nozzle pressure ratios of both jets are varied between 1 and 3, and the jet exit temperatures are maintained at near ambient conditions. Detailed surface pressure measurements show that suction pressure peaks located on the upper surface of the wing during conventional wingborne flight for angles of attack greater than 5 deg move to the wing lower surface at angles of attack less than 0 deg. A reduction in these suction pressure peaks is observed when the lift jets are operating. With sonic jet exit conditions, a freestream Mach number of 0.14, and 0 deg angle of attack, the jet-induced suckdown is equivalent to a 3.7 deg reduction in angle of attack. Schlieren, laser light sheet flow visualization and total pressure measurements in the jet plumes provide a description of the three-dimensional jet efflux flowfield. Author

NB Many AGARD publications, such as Conference Proceedings and Lecture Series, contain a number of individual papers. There is a separate citation in this index for each such paper, each containing a cross-reference (34 in this instance) to the parent publication in the form shown above. To locate the parent in this index, refer to the subject category given in the cross-reference. Within each category, citations are in numerical order.

The ability of piloted simulators to represent military and civil aviation operational tasks with ever increasing levels of fidelity is leading to a steady growth in their use for all areas of aviation from new concept studies, through support for development and flight clearance, to training aircrews for complex missions. The papers here present a variety of experience of the effectiveness of simulation for many of the key areas of application. This session focuses on: the use of simulation in aircraft development programs; the use of simulation in developing piloting skills; the use and potential of simulation in full mission training for military roles; and the effectiveness of simulation for a variety of research tasks. For individual titles, see N92-28523 through N92-28552.

This report includes the 32 technical papers developed for the High-Lift System Aerodynamics Symposium along with an edited transcript of the Round Table Discussion and a Symposium Evaluation Report. The symposium objectives were to address (1) how the most appropriate high-lift system can be selected; (2) how an efficient design can be produced; and (3) the experimental and analysis techniques which are necessary to explore and enhance the performance of a high-lift system. Thus, although the aerodynamics of high-lift systems was the dominant theme, the very pertinent aspects of weight, simplicity, reliability, and structural and mechanical integrity were an integral part of the Symposium, and were treated in the papers presented. In this sense, this Symposium has attempted to take a broader view of the high-lift system than has been taken by similar conferences in the past. For individual titles, see N94-18416 through N94-18447.

WHERE IS HIGH-LIFT TODAY? A REVIEW OF PAST UK RESEARCH PROGRAMMES
D. S. WOODWARD and D. E. LEAN *In* AGARD, High-Lift System Aerodynamics 45 p (SEE N94-18415 04-01) Sep. 1993
(AGARD-CP-515) Copyright Avail: CASI HC A03/MF A04

Some of the history of the development of slotted high-lift systems is reviewed in this paper. In particular, the National High Lift Programme run in the UK during the 1970's is reviewed in some detail. In addition, the research program in high lift since the completion of the National High Lift Programme is described qualitatively and references given. The contents cover techniques of high lift testing, results of positional optimization of slats and flaps, the derivation of a simple prediction method suitable for use with a project optimization method, and the description, with results, of a method for interpreting aerodynamic and weight data on high lift systems in the context of a complete aircraft.

In the course of four decades a large amount of high-lift applied research and development has taken place at the Fokker Company. In the fifties and sixties the F-27 and the F-28 were developed. In the eighties these aircraft were developed further into the Fokker 50 and Fokker 100. In the seventies an extensive R&D program was performed in preparation of a possible successor to the F-28 leading to the F-29 project study. In each case two- and three-dimensional wind tunnel models were investigated in numerous configurations. In the last decade these investigations have increasingly been preceded by theoretical investigations. Where data are available comparisons have been made with flight test data. Of each development program a detailed account is presented. Particular attention is paid to Reynolds-number effects and the interconnection between the high-speed cruise and low-speed high-lift design requirements. Author

HIGH ANGLE OF ATTACK: AERODYNAMICS
JOHN E. LAMAR *In* AGARD, Special Course on Engineering Methods in Aerodynamic Analysis and Design of Aircraft 39 p (SEE N92-23950 14-05) Jan. 1992
(AGARD-R-783) Copyright Avail: CASI HC A03/MF A03

The ability to predict high angle of attack, nonlinear, aerodynamic characteristics of flight vehicles, including aircraft, has made significant progress in the last 25 years using computational tools and analyses. The key technological element which has made these analyses possible is the ability to account for the influence of the shed vortical flow, prevalent in this angle of attack range, on geometries of interest. Using selected analysis techniques, applications have also been made to wing design in order to improve their high speed maneuver performance. Various techniques, associated with different levels of accuracy, exist to model this vortical flow influence. The ones included in this paper cover: suction analogy with extensions; free vortex filaments; free vortex sheet modeling; and Euler and Navier-Stokes solutions. Associated relevant features of vortices are also addressed, including: the wing and flow conditions which cause vortex formation; and how the vortex strength varies with angle of attack and wing sweep. SPECIAL COURSE ON SKIN FRICTION DRAG REDUCTION
Mar. 1992 284 p Course held in Rhode-Saint-Genese, Belgium, 2-6 Mar. 1992; sponsored in cooperation with VKI
(AGARD-R-786; ISBN-92-835-0661-8; AD-A253005) Copyright Avail: CASI HC A13/MF A03

Lecture notes for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Skin Friction Drag Reduction' have been assembled in this report. The aim and scope of this course was to provide an overview of the state of the art of current technology programs focused on reducing aircraft drag caused by skin friction. This report provides a review of recent progress in the field of skin friction drag reduction for transport aircraft. It provides a general introduction to the technology and then focuses on two specific aspects of drag reduction: maintaining laminar flow by controlling transition and manipulating the turbulence structure in boundary layers to help reduce skin friction. Technology associated with the use of riblets, LEBU, polymers, additives, etc., is also reviewed. For individual titles, see N92-27707 through N92-27714.

BASIC CONCEPTS ON BOUNDARY LAYERS
JEAN COUSTEIX *In* AGARD, Special Course on Skin Friction Drag Reduction 39 p (SEE N92-27706 18-02) Mar. 1992
(AGARD-R-786) Copyright Avail: CASI HC A03/MF A03

At the present time drag reduction is an industrial challenge in aeronautics which justifies the efforts devoted to this topic. One facet of this effort deals with the skin friction drag reduction. Two directions are followed. The first one is the manipulation of turbulent boundary layers, by altering the formation of turbulence or by modifying its characteristics it is hoped to decrease the turbulent skin friction. The second direction concerns the action on laminar-turbulent transition, by delaying the occurrence of the turbulent regime, enormous skin friction reductions are possible. It is believed that the improvements in the field are based on a better knowledge of the basic phenomena. Author

DRAG REDUCTION: AN INDUSTRIAL CHALLENGE
J. P. ROBERT *In* AGARD, Special Course on Skin Friction Drag Reduction 15 p (SEE N92-27706 18-02) Mar. 1992
(AGARD-R-786) Copyright Avail: CASI HC A03/MF A03

Over the last few decades all civil aircraft manufacturers have made great efforts to reduce aircraft drag. The long term aim of the operation is to reduce the specific fuel consumption of aircraft, the potential reduction of over 10 percent would represent savings of several million dollars for the airlines. The fuel crises have increased the need for developing new technologies to be applied on the new aircraft; retrofits, however, also have their uses. Estimating the drag of a transport aircraft through calculation or wind tunnel tests must come as close as possible to the value obtained in flight. H.A.

This paper reviews aerodynamic drag reduction for friction, wave and vortex drag associated with supersonic cruise aircraft and suggests approaches and research directions which cover the spectrum from possibly significant to revolutionary. Various synergisms are also included, especially in regard to suction laminar flow control and flow separation control at cruise. The former may also enable improved low speed, high lift systems, lift to drag ratio for subsonic cruise, reduced parasitic viscous drag for favorable interference wave drag reduction approaches, and turbulent skin friction reduction via slot injection. Flow separation control at cruise proffers opportunities for increased leading edge thrust, increased lift increment from upper surface, increased fuselage lift/camber for wave drag due to lift reduction, improved performance of various favorable interference wave drag reduction schemes, as well as possibly better low speed, high-schemes and wing cruise performance. More speculative approaches include multi-stage aircraft, thrust vectoring for lift augmentation, as well as trim, and a number of conceptual wave and vortex drag reduction schemes. Author

The basic instability mechanisms are discussed from an elementary standpoint considering only boundary layers in external flows. The objective of this report is to provide the basic ideas and results of boundary layer stability in order that one can understand transition mechanics, transition control, and transition prediction for aircraft systems. The current state of the art boundary layer stability is reviewed and by using recent results, it is shown that a number of unique transition mechanisms exist and each play a different role in the breakdown to turbulence. The control of the stability and transition characteristics of a particular flow field requires thoroughly understanding the details of these breakdown mechanisms. Author

This paper describes the practical calculation methods which are currently available to predict the transition location in two and three dimensional flows. Emphasis is given to the problem of skin friction drag reduction on swept wings at subsonic and transonic speeds. The so called e(sup n) method, which is deduced from the linear stability theory is widely used in the case of 'natural' transition, but simpler techniques (empirical criteria) are useful in more complex situations such as boundary layer tripping or leading edge contamination. The simulation of flight in wind tunnels is also discussed. Wind tunnel/flight correlation includes comparisons

between the free stream disturbance environment, the transition Reynolds number, and the n factor at transition onset. Author

The near wall turbulent eddies consist of streamwise vortices, low speed streaks, intense shear layers, inflectional velocity profiles, oscillations and ejections of low speed fluid out into the logarithmic layer. Away from the wall, large scale three dimensional outer structures dominate the flow. A mass of data has been accumulated over the past 25 years concerning these eddies and their interaction. These eddies and events will be discussed as well as their Reynolds number dependence. Author

The first part of this note concerns organized structures in the near-wall region of a turbulent boundary layer. A particular emphasis is given to those organized motions believed to be responsible for the turbulence production process in the wall region, and hence, indirectly responsible for the viscous drag. Examples are selected to illustrate how the analyses of numerically generated databases have contributed to improve our understanding of the organized structures of turbulent boundary layers. In the second part, results from an exploratory study based on the direct numerical simulation of the concepts for active control of turbulent boundary layers are presented. A significant drag reduction is achieved when the surface boundary condition is modified such that it could suppress the organized motion in the wall region. This drag reduction is accompanied by a significant reduction in the intensity of the organized structures and in the magnitude of Reynolds stresses throughout the flow. Author

The purpose of this paper is to provide a current overview of turbulent skin friction drag reduction concepts which have potential for reducing aircraft fuel consumption. These lectures are organized around four topics. First, after briefly reviewing what is known about the structure of the turbulent boundary layer, possible mechanisms for both active and passive will be discussed; concentrating on techniques offering net drag benefits, either through inner or outer layer manipulation. Both experimental and numerical results will be presented for these boundary layer manipulators. Available data and computer model predictions for low and high subsonic speeds, transonic conditions, and supersonic flow will be reviewed. The aim will be to outline the most important results obtained in terms of drag reduction, and to emphasize the most recent developments. Finally, the combination of passive devices with polymers, suction, blowing, microbubbles, or acoustic forcing will be discussed along with studies of alternative drag reducing surfaces. Author

The status of computational methods for unsteady aerodynamics and aeroelasticity is reviewed. The key features of challenging aeroelastic applications is discussed in terms of the flowfield state - low angle high speed flows and high angle vortex dominated flows. The critical role played by viscous effects in determining aeroelastic stability for conditions of incipient flow separation is stressed. The need for a variety of flow modeling tools, from linear formulations to implementations of the Navier-Stokes equations, is emphasized. Estimates of computer run times for flutter calculations using several computational methods are given. Applications of these methods for unsteady aerodynamic and transonic flutter calculations for airfoils, wings, and configurations are summarized. Finally, recommendations are made concerning future research directions. Author

The current status of unstructured grid methods developed in the Unsteady Aerodynamics Branch at NASA Langley Research Center is described. These methods are being developed for unsteady aerodynamic and aeroelastic analyses. Flow solvers that have been developed for the solution of unsteady Euler equations are highlighted. The results demonstrate two and three dimensional applications for both steady and unsteady flows. Comparisons are also made with solutions obtained using a structured grid code and with experimental data to determine the accuracy of the unstructured grid methodology. These comparisons show good agreement which thus verifies the accuracy. Author

An overview is presented of the recent in-house and contractual efforts in the area of transonic unsteady aerodynamics for aeroelasticity at the Flight Dynamics Directorate of the USAF Wright Laboratory. Three major topics are discussed. The first topic, analytical unsteady aerodynamics, involves the application of both transonic small disturbance and Euler/Navier-Stokes codes to

fighter-type aircraft. Aeroelastic calculations made with these codes are compared with test results. The second topic involves a description of unsteady pressure testing in the NLR tunnel in the Netherlands. Finally, the plan for incorporating transonic unsteady aerodynamics into structural redesign is presented. Author

The development of a time-linearization approach for solving the unsteady transonic small disturbance equation is described in UST3D simulation code (UnSteady Transonic code for a 3D isolated wing). The accuracy of the method was examined by comparing the unsteady pressure distributions with those obtained from XTRAN3S code and experiments carried out on the F-5 wing at subsonic and transonic wings to show the deficiencies of the method. Using the UST3D code, flutter analysis was carried out on the AGARD 445.6 wing. The flutter boundaries were compared with experimental results and those from CAP-TSD code. Author

A boundary integral formulation for the analysis of unsteady potential transonic flows around airplanes is presented. The formulation is applied to steady and to unsteady two dimensional and three dimensional configurations under the small perturbation assumption. The results are compared with existing numerical and/or experimental results, and demonstrate that the algorithm is capable of capturing shocks. However, the location predicted appears to be ahead of that predicted by conservative finite difference schemes; nevertheless, considering the preliminary nature of this work, the agreement obtained is quite satisfactory. Presented here are the results of unsteady transonic flow calculation methods developed at the DLR Institute of Aeroelasticity for oscillating airfoils and wings. The 2D Euler and Full Potential calculations in the nonlinear regime with pronounced shock dynamics at the conventional NACA0012 and the supercritical NLR7301 airfoil show that the unsteady pressure distributions agree well, whereas the unsteady lift and moment curves are not always in good agreement. The 3D results are obtained with a 3D Full potential code and a 3D time linearized TSD method for a swept NACA0012 wing and for a LANN wing, an AGARD standard test wing, both oscillating with small amplitudes. The agreement of the first harmonics of pressure distribution indicates that the time linearized approach may be sufficient for low amplitudes. For higher amplitudes, however, the appearance of pronounced higher harmonics indicates strong nonlinear behavior combined with complicated shock motions. Author

Numerical results of a code for computing the unsteady transonic flow in a 2D cascade of harmonically oscillating blades are given. The calculation of the flow field is based on a Euler code using flux vector splitting. After a description of the basic equations and the special numerical techniques applied to the code, results are presented for the first harmonics of pressure, lift, and moment coefficients. For the present investigations, two basic oscillation modes were chosen: tuned modes where all blades perform oscillations with the same frequency, same amplitude and a constant interblade phase angle, and mistuned modes, where all blades are oscillating with the same amplitude, but with varying frequency from one blade to another. The computed results refer to two standard configurations: a subsonic-transonic turbine cascade and a subsonic-transonic compressor cascade. In the case of tuned bending modes, the theoretical results are compared with the experimental data from the turbine standard configuration. Special attention is directed to the occurrence of aerodynamic instability in the oscillating cascade. It can be shown that the interblade phase angles at which the above mentioned experimental test case shows unstable behavior are generally well-reproduced by the computational results. Author

The numerical simulation of the unsteady Euler equations in conservative form for time-accurate problems using a relaxation method is considered. The unfactored implicit equations are solved by applying a nonlinear Newton method. Relaxation is performed with a point Gauss-Seidel algorithm ensuring a high degree of vectorization by employing the so-called checkerboard scheme. The fundamental feature of the Euler solver is a characteristic variable splitting scheme (Godunov-type averaging procedure, linear locally one-dimensional Riemann solver) based on an Eigenvalue analysis for the calculation of fluxes. Singular behavior of the coefficient matrix is evaded by a simple matrix conditioning needing only a few operations. Numerical results are presented for two and three dimensional standard AGARD configurations. The airfoils and wings at sub and transonic flows perform harmonically pitching oscillations or trailing edge flap oscillations. Comparisons with experiments show good agreement except in regions where viscous effects are evident. Author

A method was developed to determine the aerodynamic forces acting on oscillating bodies of revolution in transonic-supersonic flight. The nonlinear equation for the mean flow perturbation potential and the time linearized equation for the cross flow perturbation are both of hyperbolic type, for the Mach number range of interest, and have been solved by the method of characteristics. The method is valid for arbitrary frequencies of oscillation and can be applied for rigid or flexible body motions. Results are presented for the stability force coefficients, unsteady pressure distributions, and shock deformations for various body shapes and Mach numbers. Author

An overview is presented of unsteady inviscid calculation methods at the National Aerospace Laboratory (NLR), which are primarily based on the full potential equation for the prediction of airloads on oscillating structures in transonic flow. Attention is given to experience with entropy/vorticity corrections and a procedure which removes the frequency barrier associated with time-linearized modelings. This procedure has a favorable effect on computer cost such that transonic flutter boundaries can be obtained in acceptable turn-around times on current workstations. A method for transonic aeroelastic analysis of complete aircraft which is now in the stage of development is introduced, and attention is given to its grid generation procedure. The methods are demonstrated by showing results of unsteady loads and pressure coefficients applications in 2D and 3D transonic flow and an aeroelastic application to a 3D AGARD standard aeroelastic case in transonic flow. A Euler/Navier Stokes solution algorithm is presented for unsteady aerodynamic analysis of flows around airfoil sections. Several numerical methods have been involved in the flow solver, beginning with an explicit Runge-Kutta time-stepping scheme. Two methodological closely connected moving mesh algorithms were implemented, concerning the mesh adaption for improved accuracy with a minimal number of mesh points, and the body conforming mesh movement which is completely general and can treat realistic configurations. A description is given of the latest version of the developed implicit solving algorithm which can be used as a direct method, but also includes an option for iterating the unsteady residual to enhance the time accuracy. The included moving mesh methods for solution adapting and body conforming the grid are summarized. Numerical simulations of steady and unsteady well known flow phenomena, comprising a shock/boundary interaction, a flow around a cylinder, an airfoil with oscillating flap, and a circular arc airfoil substantiate the above mentioned topics. Progress towards the development of a 3D viscous-inviscid strong interaction method for computing unsteady transonic wing flow is reported. In the current version, an ADI technique for solving the 3D unsteady Transonic Small Perturbation (TSP) equation has been extended by incorporating an unsteady 2D integral boundary layer method and then simultaneously solving the viscous and inviscid flow equations in a stripwise fashion. Here attention is focused on the viscous part of the method, and a 3D boundary layer version is introduced. Detailed calculations of 2D unsteady and 3D incompressible/compressible turbulent boundary layers were performed by the integral methods and also by a finite difference solver, and the results are compared to experimental data. The strong interaction technique is validated by comparison with experimental pressure distributions on several airfoils and a wing for various transonic Mach numbers. For steady and unsteady flows, the computed influence of viscous displacement on the pressure distribution is demonstrated in contrast to purely inviscid calculations. Author

A method for exploring the flutter characteristics of wing-only configurations in the transonic flow regime is presented. At the heart of the method is the Unsteady Transonic Small Perturbation (UTSP) program, which solves the nonlinear transonic small perturbation equation with or without the simultaneous integration of the structural equations of motion. The aim here is to describe the functionality of the program, with a particular emphasis on its implementation within the existing aeroelastics analysis environment at the Kingston site of British Aerospace. Before demonstrating the use of the UTSP program on a production conbat wing, results for the AGARD Taileron and wing 445.6 models are presented, with the aim of validating the method. Author

Prediction of unsteady pressure distributions is an important step towards analyzing the flutter characteristics of an airplane. For this purpose, the TRANSAIR code, originally developed for predicting steady transonic flow past bodies of complex geometry, was extended to handle unsteady problems, in which the unsteady solution could be viewed as an harmonic perturbation to the steady transonic flow. The predicted unsteady flow effects were compared with linear solutions for subsonic flow problems. The predicted results were also compared with available experimental data on unsteady pressure distributions on an oscillating wing in transonic flow. In all these cases, excellent agreements were obtained. The unsteady TRANSAIR code and a structural finite element code were then used to analyze the flutter characteristics of a three dimensional wing model. The predicted flutter speeds and frequencies, including nonlinear flow effects were significantly different than those predicted by linear analysis. Further analyses including the effects of nacelles and fuselage bodies are in progress. Author

Presented here is a numerical approach for transonic aeroelasticity studies called the direct coupling method. This direct coupling is realized between the computation of aerodynamic forces and the computation of displacements. The flow is modeled by using the Transonic Small Perturbation (TSP). In steady flow, we determine the static deformations of the structure. The strong coupling insures the equilibrium state between the aerodynamic forces and the static deformations and in the steady flow between the aerodynamic and the aeroelastic forces in the time domain. The analysis of the resulting displacements give the evolution of the structural modes and enable us to detect flutter. Numerical results are presented for a civil aircraft and are compared with other methods in the frequency domain. Author

The Computational Aeroelasticity Program - Transonic Small Disturbance (CAP-TSD) code is applied to the Active Flexible Wing (AFW) wind tunnel model for prediction of the model's transonic aeroelastic behavior. A semi-span computational model is used for evaluation of symmetric motions and a full span model is used for evaluation of antisymmetric motions. Static aeroelastic solutions using CAP-TSD are computed. Dynamic flutter analyses are then performed as perturbations about the static aeroelastic deformations and presented as flutter boundaries in terms of Mach number and dynamic pressure. Flutter boundaries that take into account modal refinements, vorticity, and entropy corrections, antisymmetric motions and sensitivity to the modeling of the wing tip ballast stores are also presented and compared with experimental flutter results. TRANSONIC AEROELASTIC COMPUTATIONS ON WINGS USING NAVIER-STOKES EQUATIONS
GURU P. GURUSWAMY and SHIGERU OBAYASHI *In* AGARD, Transonic Unsteady Aerodynamics and Aeroelasticity 22 p (SEE N92-27936 18-02) Mar. 1992
(AGARD-CP-507) Copyright Avail: CASI HC A03/MF A04

Aeroelastic computations are made on fighter type wings in the transonic regime. The flow is modeled using the Navier-Stokes equations and is coupled with structural equations of motion. The flow equations are solved by a time accurate finite difference scheme with moving grids. The coupled aeroelastic equations of motion are solved using the linear acceleration method. The configuration adaptive dynamic grids are time-accurately generated using the aeroelastically deformed shape of the wing. Computations are made for oscillating rigid wings with moving shock waves in the presence of leading edge vortices. The computed results compare well with the experiment. Unsteady computations are made to demonstrate the shock-vortex interaction phenomenon on wings in ramp motion. Effects of flexibility and pitch rate are demonstrated for flows with vortices. Author

A wind tunnel investigation was conducted to investigate the unsteady aerodynamic aspects of transonic Limit Cycle Oscillations (LCO) on fighter type aircraft wings. The first test, conducted with a wing body configuration with wing stores, was restricted to incidences below 10 deg. Test results are presented with the objective of obtaining unsteady pressure and forces necessary for identifying the aerodynamic nature of transonic LCO which is currently encountered on many fighter configurations. The wing panel was oscillated in pitch at amplitudes and frequencies typical of LCO for flow conditions in which significant shock-induced separation is encountered. Unsteady pressure data were obtained for the wing panel in terms of both harmonic components and time-histories to highlight the nonlinearities. Unsteady forces and moments measured on the wing panel as well as on each wing store were also obtained to indicate the level of contribution of each element to the overall unsteady wing loads for pitching motions. An experimental effort was implemented in aeroelasticity called the Benchmark Models Program. The primary purpose of this program is to provide the necessary data to evaluate computational fluid dynamic codes for aeroelastic analysis. It also focuses on increasing the understanding of the physics of unsteady flows and providing data for empirical design. An overview is given of this program and some results obtained in the initial tests are highlighted. The tests that were completed include measurement of unsteady pressures during flutter of a rigid wing with an NACA 0012 airfoil section and dynamic response measurements of a

flexible rectangular wing with a thick circular arc airfoil undergoing shock boundary layer oscillations. Author

FURTHER INVESTIGATION OF THE EFFECT OF MODEL COOLING ON PERIODIC TRANSONIC FLOW
S. RAGHUNATHAN (Queens Univ., Belfast (Northern Ireland).), F. ZARIFI-RAD (Queens Univ., Belfast (Northern Ireland).), and D. G. MABEY (Royal Aerospace Establishment, Bedford, England) *In* AGARD, Transonic Unsteady Aerodynamics and Aeroelasticity 13 p (SEE N92-27936 18-02) Mar. 1992
(AGARD-CP-507) Copyright Avail: CASI HC A03/MF A04

An experimental investigation of the effect of model cooling on transonic periodic flows on biconvex airfoils is reported. The test conditions included shock interactions with laminar and turbulent boundary layers at a Reynolds number of 0.9 million and model wall temperature to tunnel total temperature ratios 0.5 to 1.0. The results show large effects of model cooling on transonic periodic flows. The effects observed are thought to correspond to what would happen at high Reynolds numbers at adiabatic wall temperatures. Author

The importance of scale effects is recognized generally in steady aerodynamics but is often ignored in unsteady aerodynamics. An attempt is made to remedy this situation by the compilation of a review of information on the influence of Reynolds number from a wide range of unsteady aerodynamic tests, with particular reference to wing flows. The unsteady tests considered here relate to surfaces in unsteady motion and include dynamic tests of airfoils and wings, pressure measurements, oscillatory control surface derivatives, and stability derivatives. Here, it is suggested that for the recommended model conditions with fixed transition, scale effects are small for fully attached or well-separated flows, but may be close to incipient separation. With fixed transition, extrapolation from model to full-scale Reynolds numbers is usually possible. In contrast, with free transition, scale effects can be large for both attached and separated flows, and extrapolation from model to full-scale Reynolds numbers is usually extremely difficult. Some test cases for the prediction of scale effects in unsteady aerodynamics are suggested. Author

The principal emphasis of the meeting was to be on the understanding and prediction of separation-induced vortex flows and their effects on vehicle performance, stability, control, and structural design loads. This report shows that a substantial amount of the papers covering this area were received from a wide range of countries, together with an attendance that was even more diverse. In itself, this testifies to the current interest in the subject and to the appropriateness of the Panel's choice of topic and approach. An attempt is made to summarize each paper delivered, and to relate the contributions made in the papers and in the discussions to some of the important aspects of vortex flow aerodynamics. This reveals significant progress and important clarifications, but also brings out remaining weaknesses in predictive capability and gaps in understanding. Where possible, conclusions are drawn and areas of continuing concern are identified. Author

AERODYNAMIC ANALYSIS OF SLIPSTREAM/WING/NACELLE INTERFERENCE FOR PRELIMINARY DESIGN OF AIRCRAFT CONFIGURATIONS
C. M. VANBEEK, W. J. PIERS, and B. OSKAM *In* AGARD, Aerodynamic Engine/Airframe Integration for High Performance Aircraft and Missiles 20 p (SEE N93-13199 03-34) Sep. 1992 Sponsored by Netherlands Agency for Aerospace Programs
(AGARD-CP-498) Copyright Avail: CASI HC A03/MF A04

A panel method based model for the computation of the time-averaged influence of a propeller slipstream on the aerodynamic characteristics of an aircraft configuration is described. The slipstream model is based on the simplifications that the single-rotating propeller is replaced by an actuator disk and that all the vorticity of the slipstream is represented on a cylindrical sheet of fixed geometry which envelops the slipstream in combination with a discrete vortex at the axis of the slipstream. Appropriate jump conditions across the actuator disk and boundary conditions on the cylindrical sheet, solved simultaneously with the boundary conditions on the aircraft configuration, yield the mutual influence of the propeller and the slipstream on the aerodynamic characteristics of the aircraft configuration. This slipstream model is incorporated in a three-dimensional panel method. Computed lift increments due to the slipstream are presented for a realistic wing/nacelle/fuselage-configuration and compared with wind-tunnel data for several thrust coefficients and angles of attack of the aircraft. A common design of inlet model (RAE Model 742L Cowl 2), but built to slightly different scales (convenient to the specific wind tunnel), was investigated in the RAE 8 ft x 8 ft tunnel, the ONERA S2MA-tunnel (1.75 m x 1.77 m), and the transonic 1 m x 1 m wind tunnel (TWG) of DLR. The measurements were carried out at subsonic and supersonic Mach numbers, at several Reynolds numbers and angles of attack. The paper presents--aside of a short description of the wind tunnels and the models--details of the instrumentation and the formulae used to calculate the steady-state and the instantaneous distortion parameters. A brief description of the data acquisition and reduction systems is also given. Results of the three tests are presented in the usual format, and from the comparison of the results the differences are analyzed and the main origins of the discrepancies discussed and explained. Finally some recommendations are given for reducing those discrepancies in further tests. Author

The Tactical Missile Division has been using ramjets on its missiles for more than thirty years. The adaptation of this type of propulsion to very high speed aircraft and airbreathing launchers is investigated. We must study vehicles designed for higher and higher speeds, and we need to optimize more rapidly, and at a lower cost, our airbreathing missile configurations. We completed our supersonic air intake design methodology by using CFD for our work in external and internal aerodynamics. These CFD tools involving Euler and Navier-Stokes codes and mesh generators are complementary to wind tunnel tests. Author

Modern aircraft require intake and nozzle flows to be closely integrated with the airframe, and various layouts are possible. In some cases, the intake/nozzle is integral with the fuselage providing a relatively 'compact' layout. This contrasts with configurations in which the nacelles are displaced from the fuselage but are near lifting surfaces. Engine intake flow conditions may range from very high Mass Flow Ratio (MFR) at take-off, to very low MFR on approach, and may include zero MFR during inflight shut-downs. The effect of the intake flows on adjacent components will vary with intake MFR, aircraft attitude, and Mach number. Designers need to know the magnitude of these effects to ensure that they can be contained to satisfactory levels within the available control parameters. A first-order panel method was used to analyze the MFR effects on several configurations. These range from simple 'generic' types to complex, Canard-Delta configurations and include various intake and nozzle arrangements. Mach number and asymmetric effects were studied in particular cases. Author

(AGARD-CP-519) Copyright Avail: CASI HC A02/MF A04

This paper presents an overview of the test campaign performed on the Piaggio P.180 'Avanti' aircraft in order to develop and obtain the maximum natural laminar flow on the lifting surfaces. The paper reports the development of new profile family that could allow not only good laminarity flow characteristics in the aircraft flight envelope but also favorable pressure distribution and performance results. The wind tunnel and in-flight visualization as well as the effects of natural laminar flow airfoil contamination are herein described. Sublimating chemicals techniques have been employed to test the design airfoils even if this approach allowed only one test point per flight. Positive results were however achieved and demonstrated the positive effects of such a design philosophy. Author

Accurate aircraft delivery of unguided munitions requires that an aircraft onboard targeting algorithm account for the free-stream drag characteristics of a released store as well as the effects of ejection forces and aircraft-induced aerodynamic flow-field transients. Of the three, aerodynamic flow-field effects are the most difficult to predict. The current state of weapon delivery technology requires that many hours of flight testing be conducted and the test data analyzed to form a significant foundation upon which to build an accurate flow-field compensation algorithm. The proposed use of ground simulation techniques in lieu of flight test techniques to achieve accurate aircraft delivery of unguided weapons is the thesis of this paper. A method was developed to permit application of ground simulation techniques to the challenging arena of aircraft weapon delivery accuracy. The method was tested by correcting a flow-field compensation algorithm for a typical supersonic tactical aircraft and comparing the resultant aircraft bombing accuracy with that attained using traditional state-of-the-art flight testing techniques. Preliminary results indicate that good aircraft bombing accuracy can be achieved using only ground simulation techniques. Success of the method offers the potential to reduce the cost of producing an accurate aircraft weapon delivery algorithm by an order of magnitude and the time required by three-fourths. Planned future efforts will attempt to expand method validity into increasingly demanding regions of the flight envelope. Author

Papers prepared for the AGARD Fluid Dynamics Panel Symposium on theoretical and experimental methods in hypersonic flows held on 4-8 May 1992 are presented. The objectives of the Symposium were to (1) report and assess the advances being made by the AGARD community on the development and application of theoretical methods and experimental techniques for simulating hypersonic flows over aerospace vehicles; (2) highlight outstanding problem areas; and (3) establish pointers to aid in the planning and implementation of future research programs. Major topics covered by the Symposium were testing techniques and instrumentation, computational methods and physical modeling, and validation and accuracy assessment. For individual titles, see N94-10422 through N94-10465.

Design studies are underway for a variety of hypersonic flight vehicles. The National Aero-Space Plane will provide a reusable, single-stage-to-orbit capability for routine access to low earth orbit. Flight-capable satellites will dip into the atmosphere to maneuver to new orbits, while planetary probes will decelerate at their destination by atmospheric aerobraking. To supplement limited experimental capabilities in the hypersonic regime, computational fluid dynamics (CFD) is being used to analyze the flow about these configurations. The governing equations include fluid dynamic as well as chemical species equations, which are being solved with new, robust numerical algorithms. Examples of CFD applications to hypersonic vehicles suggest an important role this technology will play in the development of future aerospace systems. The computational resources needed to obtain solutions are large, but solution adaptive grids, convergence acceleration, and parallel processing may make run times manageable.

Several analytical aerodynamic design tools that were applied to the Pegasus air-launched space booster were evaluated using flight measurements. The study was limited to existing codes and was conducted with limited computational resources. The flight instrumentation was constrained to have minimal impact on the primary Pegasus missions. Where appropriate, the flight measurements were compared with computational data. Aerodynamic performance and trim data from the first two flights were correlated with predictions. Local measurements in the wing and wing-body interference region were correlated with analytical data. This complex flow region includes the effect of aerothermal heating magnification caused by the presence of a corner vortex and interaction of the wing leading edge shock and fuselage boundary layer. The operation of the first two missions indicates that the aerodynamic design approach for Pegasus was adequate, and data show that acceptable margins were available. Additionally, the correlations provide insight into the capabilities of these analytical tools for more complex vehicles in which design margins may be more stringent. Author

LOCAL MEASUREMENT OF TEMPERATURES AND CONCENTRATIONS: A REVIEW FOR HYPERSONIC FLOWS

C. DANKERT (Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Goettingen, Germany.), R. CATTOLICA (California Univ., San Diego.), and W. SELLERS *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 10 p (SEE N94-10421 01-02) Apr. 1993

(AGARD-CP-514) Copyright Avail: CASI HC A02/MF A04

The quality of reentry simulation for Shuttle, HERMES, Sanger, and NASP systematically suffers from the strong non-equilibrium of rotational and vibrational temperature due to the rapid acceleration of the test gas in the nozzle. Therefore the determination of temperatures is necessary and, if possible, preferable by a non-intrusive technique. The specific interests of this review are optical techniques such as electron beam fluorescence, laser-induced fluorescence, and coherent anti-Stokes Raman scattering. The capabilities available for local measurements with temporal resolution and quantitative accuracy are discussed for velocity, temperature, density, species concentrations, and fluctuations due to turbulence. The applicability of these methods of measurement is presented and discussed for the coming topic in aerothermodynamics: experimental techniques of hot gases in high enthalpy flows. Author

A review of measurement techniques used to obtain aerodynamic forces and moments and surface/flow field pressures for models tested in impulse hypersonic-hypervelocity facilities and in conventional-type hypersonic wind tunnels is presented. Although force and moment measurement techniques presently used in hypersonic wind tunnels are relatively unchanged from the 1960's and 1970's, significant advances have recently been made for impulse facilities. For both hypersonic wind tunnels and impulse facilities, the state-of-the-art has advanced via refinements, improved test techniques, and advances in semiconductor technology, data acquisition systems, and computers. The introduction of electronically scanned pressure systems over a decade ago 'revolutionized' pressure measurements in hypersonic wind tunnels and a second 'revolution' is impending with the development and application of optical, two-dimensional, global pressure measurement techniques. The development and continued refinement of miniature piezoresistive transducers has provided the capability to perform detailed surface pressure measurements on relatively small, complex models in impulse facilities; these transducers also provided the capability for intrusive flow field pressure measurements with miniature survey rakes. SYNTHESIS OF THE WORKSHOP ON HYPERSONIC FLOWS FOR REENTRY PROBLEMS

REMI ABGRALL, JEAN-ANTOINE DESIDERI, MICHEL MALLET (Avions Marcel Dassault, Saint-Cloud, France.), JACQUES PERIAUX (Avions Marcel Dassault, Saint-Cloud, France.), PIERRE PERRIER (Avions Marcel Dassault, Saint-Cloud, France.), and BRUNO STOUFFLET (Avions Marcel Dassault, Saint-Cloud, France.) *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 23 p (SEE N94-10421 01-02) Apr. 1993 Workshop held in Antibes, France, Jan. 1990 and Apr. 1991

(AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

One of the most challenging problems of modern aerospace engineering is undoubtedly the prediction of hypersonic flows around reentry vehicles. Indeed this challenge has many aspects: defining the appropriate physical model for these flows is the first difficulty since very complex physical and chemical phenomena take place during the reentry phase; moreover, temperature, velocity, and enthalpy are very high, density very low, making the reentry conditions very difficult to reproduce in ground-based experiments. Thus, in the past two decades, important efforts in computational fluid dynamics have been made employing supercomputers to simulate these complex flows. However, most simulation tools were originally designed for transonic or supersonic flow applications and later extended; these usually contain imperfect models, and also still have to be improved to permit

the accurate prediction of hypersonic flows. This situation has motivated strong international cooperative efforts including three Europe/US Short Courses on Hypersonics and two sessions (Part 1 and 2) of the scientific workshop organized by INRIA and GAMNI which took place in Antibes, France. Part 1 brought together a group of experts active in hypersonics, and promoted direct comparisons of codes and experiments. The main objective of part 2 was to improve the quality of both experimental and computational results, and evaluate numerical codes by code-to-code or code-to-experiment comparisons, and permit a better confidence in the prediction tools to be used in the design of hypersonic vehicles. The presentation is aimed at reporting the main conclusions as they were expressed at the meeting by experts, including some of their recommendations regarding the validation of numerical codes. (AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

The investigation is concerned with the understanding of the structure of the hypersonic flow developed in a circular pipe. The experiments were conducted in the University of Toronto Institute for Aerospace Studies (UTIAS)/Ryerson Polytechnical Institute (RPI) gun tunnel at a freejet Mach number of 8.30 and Reynolds number based on the pipe diameter, Re = 2.44 x 10(exp 6). Wall static pressure, as well as in-stream static and pitot pressure measurements at several sections in the pipe, shed some light into the physical nature of the considered flow. The measurements indicate that shocks generated in the pipe flow are primarily oblique. Measurements near the pipe axis and in wave structures presented some difficulties. Further work is needed to clarify certain features of the investigated flow. The presented results may guide the development of computational fluid dynamic codes applicable to hypersonic pipe flows. EXPERIMENTAL AND COMPUTATIONAL COMPARISONS OF MACH 6 HIGH REYNOLDS NUMBER HEAT TRANSFER AND SKIN FRICTION

LELLO GALASSI and NORMAN E. SCAGGS *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 14 p (SEE N94-10421 01-02) Apr. 1993

(AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

Wind tunnel measurements on a flat plate, ogive cylinder, and a compression ramp at zero angle-of-attack are compared to computational fluid dynamics (CFD) predictions of the flow parameters. These models provide a zero-pressure gradient, favorable-pressure gradient, and an adverse-pressure gradient flow condition, respectively. Results are presented for surface pressure and temperature distributions, boundary layer surveys, heat transfer rates, and local skin friction coefficients. Test conditions were varied over a free-stream Reynolds number range of 0.45-9.1 (10 exp 7) per meter, at a nominal Mach number of 6. Wind tunnel measurements on the three models were made using static pressure ports, embedded thermocouples, coaxial heat transfer gauges, slug calorimeters, Preston tube skin friction devices, and skin friction force balances. Boundary layer profiles were measured with total temperature and pitot pressure probes and with laser doppler velocimetry. Parabolized Navier-Stokes and full Navier-Stokes code predictions of the measured parameters are compared to experimental measurements. Results indicate surface pressure distributions are easily predicted by the CFD codes used and for the simple geometries modeled. For CFD codes which predict the surface heat transfer rate accurately, the local skin friction coefficient agrees to within 7-10 percent of the measured data for favorable-pressure gradient and zero-pressure gradient configurations. For adverse-pressure gradients, the code used did not predict skin friction values accurately, although heat transfer predictions matched the data. Large gradients in the hypersonic boundary layer require dense grids near the model surface in order for CFD codes to accurately predict the surface heat transfer rate and the local skin friction coefficient. Additionally, dense grids in the streamwise direction are necessary to properly resolve the boundary layer for adverse-pressure gradients. Author (revised)

EXPERIMENTAL, ANALYTICAL, AND COMPUTATIONAL METHODS APPLIED TO HYPERSONIC COMPRESSION RAMP FLOWS

G. SIMEONIDES, W. HAASE (Dornier Luftfahrt G.m.b.H., Friedrichshafen, Germany.), and M. MANNA *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 12 p (SEE N94-10421 01-02) Apr. 1993

(AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

Experimental data on fully laminar and transitional shock wave boundary layer interactions in two-dimensional compression corners are provided and used for the validation of two full Navier-Stokes solvers, as well as for checking the capabilities and limitations of simple analytical prediction methods. Viscous pressure interaction, free interaction, and inviscid oblique shock theory are found to predict well the pressure levels on the flat plate upstream of the interaction, within the separated region and downstream of the interaction, respectively. The reference temperature theory is found to perform well in attached flow regimes both upstream and downstream of the interaction region, and to provide the basis for a universal peak heating correlation law. Full Navier-Stokes computations are necessary, however, to predict the extent of the interaction region and the associated influence upon the pressure distribution (control effectiveness) as well as the detailed heat transfer distribution. To achieve this, very fine gridding coupled with the use of strict convergence criteria (based on the evolution of the location of the separation point rather than on standard density residuals) is shown to be necessary. It is finally shown that, although sophisticated turbulence models need to be further developed before the detailed characteristics of fully turbulent shock wave boundary layer interactions may be predicted, transitional interactions (where transition typically occurs in the neighborhood of reattachment) may be adequately handled by algebraic turbulence models 'switched on' just downstream of reattachment. A closely coupled computational and experimental aerodynamics research program was conducted on a hypersonic vehicle configuration at Mach 8. Aerodynamic force and moment measurements and flow visualization results were obtained in the Sandia National Laboratories hypersonic wind tunnel for laminar boundary layer conditions. Parabolized and iterative Navier-Stokes simulations were used to predict flow fields and forces and moments on the hypersonic configuration. The basic vehicle configuration is a spherically blunted 10 deg cone with a slice parallel with the axis of the vehicle. On the slice portion of the vehicle, a flap can be attached; flap deflection angles of 10 deg, 20 deg, and 30 deg were used. Comparisons are made between experimental and computational results to evaluate the quality of each and to identify areas where improvements are needed. This extensive set of high-quality experimental force and moment measurements is recommended for use in the calibration and validation of computational aerodynamics codes.

Critical issues concerning the modeling of low density hypervelocity flows where thermochemical nonequilibrium effects are pronounced are discussed. Emphasis is on the development of validated analysis tools, and the activity in the NASA Ames Research Center's Aerothermodynamics Branch is described. Inherent in the process is a strong synergism between ground test and real gas computational fluid dynamics (CFD). Approaches to develop and/or enhance phenomenological models and incorporate them into computational flowfield simulation codes are discussed. These models were partially validated with experimental data for flows where the gas temperature is raised (compressive flows). Expanding flows, where temperatures drop, however, exhibit somewhat different behavior. Experimental data for these expanding flow conditions is sparse and reliance must be made on intuition and guidance from computational chemistry to model transport processes under these conditions. Ground based experimental studies used to provide necessary data for model development and validation are described. Included are the performance characteristics of high enthalpy flow facilities, such as shock tubes and ballistic ranges. Author (revised)

A coordinated computational and experimental study was made of blunt-body flows with nonequilibrium chemistry. The temperature range was such that significant dissociation of oxygen was expected but very little dissociation of nitrogen. Both pure oxygen, O2 and O, and air, treated computationally using a five species (O2, N2, NO, N, and O) model were studied. Results obtained using different published values of the chemical rate coefficients were compared and assessed for a model problem. The effects of size (i.e., Damkohler number) and freestream velocity were also investigated. The flow computations used an explicit timemarching method based on a TVD version of the MacCormack predictor-corrector scheme. A point implicit TVD method was developed to deal with the stiffness problems introduced by the finite rate chemistry. Interferograms of the flow obtained in a shock tunnel are compared with the computational results. The bow shock wave shape and the shock detachment which are dependent on the degree of chemical reaction and thermal excitation of the gas show that the calculation method is promising. A summary of three-dimensional simulations on the hypersonic rarefied flows in an effort to understand the highly nonequilibrium flows about space vehicles entering the Earth's atmosphere for a realistic estimation of the aerothermal loads is presented. Calculations are performed using the direct simulation Monte Carlo method with a five-species reacting gas model, which accounts for rotational and vibrational internal energies. Results are obtained for the external flows about various bodies in the transitional flow regime. For the cases considered, convective heating, flowfield structure and overall aerodynamic coefficients are presented and comparisons are made with the available experimental data. The agreement between the calculated and measured results are very good. Author (revised)

A numerical method was developed to compute the axisymmetric flow over blunt slender bodies with high accuracy to enable reliable analysis of the stability properties. The flow field is obtained using the Beam-Warming method to solve the thin-layer Navier-Stokes equations. The code was thoroughly validated and applied to compute the laminar flow over a long blunt cone with 7 deg half-angle at M(sub infinity) = 8. The linear stability of this flow was analyzed with highly accurate finite-difference and spectral methods. The results are compared with previous numerical studies and the experimental data of Stetson et al. Author (revised)

The effects of nonequilibrium chemistry and three dimensionality on the stability characteristics of hypersonic flows are discussed. In two-dimensional (2-D) and axisymmetric flows, the inclusion of chemistry causes a shift of the second mode of Mack to lower frequencies. This is found to be due to the increase in size of the region of relative supersonic flow because of the lower speeds of sound in the relatively cooler boundary layers. Although this shift in frequency is present in both the equilibrium and nonequilibrium air results, the equilibrium approximation predicts modes which are not observed in the nonequilibrium calculations (for the flight conditions considered). These modes are superpositions of incoming and outgoing unstable disturbances which travel supersonically relative to the boundary-layer edge velocity. Such solutions are possible because of the finite shock stand-off distance. Their corresponding wall-normal profiles exhibit an oscillatory behavior in the inviscid region between the boundary-layer edge and the bow shock. For the examination of three-dimensional (3-D) effects, a rotating cone is used as a model of a swept wing. An increase of stagnation temperature is found to be only slightly stabilizing. The correlation of transition location (N = 9) with parameters describing the crossflow profile is discussed. Transition location does not correlate with the traditional crossflow Reynolds number. A new parameter that appears to correlate for boundary-layer flow was found. A verification with experiments on a yawed cone is provided. Author (revised)

The extension of simple methods for the prediction of skin friction and heat transfer at an infinite-swept attachment line to cover the hypervelocity flight regime including the effects of surface transpiration is considered. The analysis is limited to the situation where the flow is in thermochemical equilibrium everywhere. Real gas effects are identified and their influence is quantified. The importance of freestream conditions and attachment-line inclination are assessed. Consideration is also given to the issue of boundary layer transition. Author (revised)

In view of the prevailing discrepancies between experiment and theory with regard to instabilities in hypersonic flow, an extended theoretical approach is studied. For hypersonic flow past a pointed cone Thin Layer Navier Stokes solutions are compared to similarity solutions with different modeling of viscosity-temperature laws. The formulation of the stability equations in curvilinear coordinates allows a discussion of various representations of the local body metric. A systematic sensitivity study of basic state profiles and spatial amplification rates is performed. It is found that the improved agreement with the experiment in the viscous first mode region is equally due to the extended stability analysis, where cone metric is specified, and the extended mean flow solution as well. In the second mode region the major improvement results from the more complete basic state formulation, however, the close agreement with measured growth rates is only achieved when the stability analysis is based on conical metric. Results from current studies on slender bodies of revolution tested at a nominal Mach number of 9 are presented. It concentrates on the case of a spherically-blunted cone, providing kinetic heating data for laminar, turbulent, and transitional flow regimes. Nose blunting exerts a powerful control on the location of transition, and the quantitative measurements of this location using thin film gauge techniques are supported by flow visualization using liquid crystal thermography. We also discuss work and plans for two other studies which are in their early stages: these are a cavity-induced separation and the development of turbulent boundary layers under controlled pressure gradients. Preliminary computations using a high resolution Navier-Stokes code are also presented. Author (revised)

An implicit finite-volume method for investigating viscous flows in a state of chemical and vibrational nonequilibrium in nozzles is presented. The ideal-fluid flux terms are calculated by a decentered Roe-type scheme that is second order in space, and the viscous fluxes are determined using a centered scheme. The numerical fluxes and the sources terms are coupled completely at the implicit stage. The proposed method is illustrated by application to two flow configurations: (1) a test case from the Antibes Workshop on hypersonic flows, and (2) a nozzle flow in the ONERA F4 wind tunnel. AIAA

The interest in hypersonic flow was renewed through the Hermes European program. A better knowledge of chemical and thermodynamical nonequilibrium processes connected with aerodynamic aspects is needed to study the reentry phase of the shuttle Hermes. Around this research area, many numerical approaches, taking into account more or less complicated nonequilibrium models, were developed. In order to validate these computations, different hypersonic facilities were built or are being designed. In these facilities, the hypersonic air flow is obtained at the exit of a convergent-divergent nozzle in which the reservoir enthalpy level is such that dissociation of diatomic molecules occurs. It is of upmost importance to be able to compute the flowfield in these nozzles, in order to ascertain the upstream conditions in front of the model being studied. The aim is a numerical study of hypersonic laminar inviscid/viscous flows, taking into account, on one hand, a complete description of chemical and thermodynamical nonequilibrium processes in an inviscid flow and on the other hand, the viscous effects through solving the Navier-Stokes equations for a real gas mixture with a simplified model for the vibrational nonequilibrium effects of diatomic species. Some studies made during a collaboration between the Italian Aerospace Research Center (CIRA) and Alenia D.V.D., whose aim is to provide proper validation of CFD codes in hypersonic flow regime, are described. In fact, in our opinion, the combination of numerical and experimental tools should give a better theoretical understanding of such types of flow. Numerical methods able to give accurate prediction of hypersonic flows in hypersonic wind tunnels were developed and the results obtained by calculations are compared with experimental data gathered by CIRA. Alenia equilibrium three-dimensional Euler solver, originally developed to solve transonic flows and now extended to hypersonic ones, and a non-equilibrium two-dimensional Euler solver, developed by CIRA for the Hermes program, were used to get test chamber predictions. BERGMAN (Royal Inst. of Tech., Stockholm, Sweden.) *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 11 p (SEE N94-10421 01-02) Apr. 1993 Sponsored in part by Commission Suisse d'Encouragement des Recherches Scientifiques

(AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

An international collaboration on the development of multi block flow solvers using structured grids is presented. The flow equations are solved by the finite volume method using a space centered, explicit time marching scheme augmented by artificial dissipation terms. Implicit residual smoothing is used to accelerate convergence to steady state. The multi block flow solvers are written on top of the MEMCOM data base system which provides the data structure, and use a Dynamic Memory Manager to allocate the necessary storage for each block. The Euler solver EULMB can be used to simulate hypersonic flows including equilibrium and nonequilibrium air chemistry. Recently the Euler solver has been extended to solve the Navier Stokes equations for laminar caloric perfect gas flows (NSMB flow solver). Calculated results for the calculation of the flow over a double ellipsoid and over

the HERMES space shuttle are presented. The inviscid calculations around HERMES showed that if one is only interested in the aerodynamic coefficients, equilibrium air calculations are sufficient. Parallel computations showed that the communication overhead between blocks is less than 0.5 percent, showing that the multi block concept is very promising for using parallel computers efficiently. The development of an algorithm for the solution of the compressible Euler equations at high Mach numbers on unstructured tetrahedral meshes is described. The basic algorithm is constructed in the form of a central difference scheme plus an explicit added artificial viscosity based upon fourth order differences of the solution. The stability of the solution in the vicinity of strong gradients is preserved by the incorporation of an additional artificial viscosity based upon a second order difference. Higher order accuracy is regained by using the ideas of flux corrected transport to limit the amount of added viscosity. The solution is advanced to steady state by means of an explicit multi-stage time-stepping method. The computational efficiency of the complete process is improved by incorporating an unstructured multigrid acceleration procedure. A number of flows of practical interest are analyzed to demonstrate the numerical performance of the proposed approach. Author

A study of viscous and inviscid hypersonic flows, using generalized upwind methods, is presented. A new family of hybrid flux splitting methods is examined for hypersonic flows. A hybrid method is constructed by the superposition of the Flux Vector Splitting (FVS) method and second order artificial dissipation in the regions of the strong shock waves. The conservative variables on the cell faces are calculated by an upwind extrapolation scheme third order of accuracy. A second order accurate scheme is used for the discretization of the viscous terms. The solution of the system of equations is succeeded by an implicit unfactored method. In order to reduce the computational time a Local Adaptive Mesh Solution (LAMS) method is proposed. LAMS method combines the mesh sequencing technique and the local solution of the equations. Local solution of either Euler or Navier-Stokes equations is applied in the region of the flow field where numerical disturbances are died out slowly. Validation of the Euler and Navier-Stokes codes is obtained for hypersonic flows around blunt bodies. Real gas effects are introduced via a generalized equation of state. Extension of numerical methods in real gas hypersonics is presented for the hybrid FVS method and a Riemann solver. Author

(AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

A detailed comparison of numerical results obtained by solving the Euler equations for the inviscid flow over delta wings in reentry configurations is presented. The investigation involves a side-by-side comparison between independently developed upwind Euler solvers at VKI (M3D) and NASA Johnson Space Center (E3D) using identical grids. In both solvers the governing equations are integrated by means of time marching finite volume shock capturing methods, based on a cell centered upwind evaluation of the cell face fluxes and nonlinear limiters. High resolution schemes are obtained via MUSCL characteristic variable extrapolation to ensure total variation diminishing (TVD) properties and therefore monotonic discontinuity capturing. Further comparisons are made with several published results by other authors based on both upwind and central discretizations. The present results contribute in asserting the high resolution upwind TVD schemes as the most reliable numerical technique to handle the strong discontinuities typical of high speed flows. The performances of the two upwind solvers are satisfactory and the numerical results in good agreement. However, the important issue of reaching a grid converged solution for the present complex three-dimensional inviscid flow problems was not achieved. Author (revised)

The objective is to present results obtained with the Navier Stokes code used by Dassault Aviation for aerothermal reentry problems. We will emphasize the strategy employed and only give an outline of the numerical technique developed for each solver involved in the calculation. The method is designed to have a wide range of application. It involved a sequence of calculations using different modules and interfaces. This tool is not only multi-codes but also multi-computers. The preparation of the initial solution sets for computations were performed on our IBM ES 9000/820 with MVS ESA operating system, and most of the computation was done on a NEC SX3 (at NLR in the Nederlands) and on a CRAY YMP (at C.I.R.A. in Italy) with UNIX operating system. We shall present a validation case using the complete sequence, and afterwards a number of critical points of microaerothermodynamics. The validation test case is a Complete Hermes canopy of the 0.0 geometry (shape number 185 in Dassault catalog). A model of this shape was tested in R3CH ONERA wind tunnel yielding experimental results that are used for comparison. For the flight cases we plan to compute: various canopy shapes; a meteorite impact on the Hermes noze cap; and joint between tiles (in first tile position). Author (revised)

A two-temperature model was developed for the description of thermal and chemical nonequilibrium viscous hypersonic flows. The model employs a vibrational coupling factor as proposed by Treanor and Marrone, and it uses a model based on a non-preferential removal of vibrational energy. The technique relies on a finite volume approach based on a second order accurate Total Variation Diminishing (TVD) formulation that accounts for thermal and chemical nonequilibrium effects. The stiffness due to the disparity

in time scales is reduced by introducing a precondition matrix that allows a pointwise implicit solution of the source terms. Applications of the model to compute viscous hypersonic flows over a wedge and a cylinder showed that the postshock temperature plays a fundamental role in the achievement of thermal equilibrium and that the boundary layer is the most affected by thermal nonequilibrium. The flow field around multi-element aerofoil sections possesses a high degree of complexity. Due to the strong interactions between wakes from the upstream elements and the upper surface boundary layers developing on the downstream elements, there are thick viscous layers present over the upper surface of the trailing edge flap. Large regions of separated flow can be present, even for conditions well below maximum lift. Finally, the flow around the leading edge slat can become locally supersonic, even for low freestream Mach numbers, due to the large suction levels induced in this region. The viscous-inviscid interaction methods, which are most widely in use for the prediction of multi-element aerofoil flows, are computationally very efficient, but unable to describe many of the complex flow features present. A more complete description of the physical phenomena can be achieved only by methods based on a solution of the Reynolds-averaged Navier-Stokes equations, in conjunction with a suitable turbulence model. The generation of a suitable computational grid then becomes a major problem. Within the present work, a method to generate suitable block structured grids around multi-element aerofoils has been developed. The Dornier 2-D block structured Navier-Stokes solver has been extended for grids with arbitrary block structure. After very encouraging results for a two-element high lift system at low angles of attack, in this work the method was applied for realistic two- and three-element high lift systems at high angles of attack. This paper presents Navier-Stokes calculations of the turbulent flow around two different high-lift configurations, for which experimental data exist. In the calculations, the flow field is considered as of steady-state and two-dimensional. Because of the low Mach numbers, the fluid is treated as incompressible. The solution procedure uses a finite volume method in order to solve the Reynolds-averaged Navier-Stokes equations. The effects of turbulence on the mean flow field are described by the k-epsilon turbulence model. The computational mesh is systematically refined in order to assess numerical solution errors. The results presented in this paper include surface pressure distributions as well as mean velocities and turbulence quantities. If possible, the calculations are compared to experimental data. The incompressible, viscous, turbulent flow over single and multi-element airfoils is numerically simulated in an efficient manner by solving the incompressible Navier-Stokes equations. The solution algorithm employs the method of pseudo compressibility and utilizes an upwind differencing scheme for the convective fluxes, and an implicit line-relaxation scheme. The motivation for this work includes interest in studying high-lift take-off and landing configurations of various aircraft. In particular, accurate computation of lift and drag at various angles of attack up to stall is desired. Two different turbulence models are tested in computing the flow over an NACA 4412 airfoil; an accurate prediction of stall is obtained. The approach used for multi-element airfoils involves the use of multiple zones of structured grids fitted to each element. Two different approaches are compared; a patched system of grids, and an overlaid Chimera system of grids. Computational results are presented for two-element, three-element, and four-element airfoil configurations. Excellent agreement with experimental surface pressure coefficients is seen. The code converges in less than 200 iterations, requiring on the order of one minute of CPU time on a CRAY YMP per element in the airfoil configuration. Author (revised)

A study of Navier-Stokes calculations of flows about multielement airfoils using a chimera grid approach is presented. The chimera approach utilizes structured, overlapped grids which allow great flexibility of grid arrangement and simplifies grid generation. Calculations are made for two-, three-, and four-element airfoils, and modeling of the effect of gap distance between elements is demonstrated for a two element case. Solutions are obtained using the thin-layer form of the Reynolds averaged Navier-Stokes equations with turbulence closure provided by the Baldwin-Lomax algebraic model or the Baldwin-Barth one equation model. The Baldwin-Barth turbulence model is shown to provide better agreement with experimental data and to dramatically improve convergence rates for some cases. Recently developed, improved farfield boundary conditions are incorporated into the solver for greater efficiency. Computed results show good comparison with experimental data which include aerodynamic forces, surface pressures, and boundary layer velocity profiles. Author

A numerical method is presented for the solution of the compressible Reynolds-averaged, thin-layer Navier-Stokes equations on structured composite grids as applied to high-lift configurations. The method is an adaptation of an implicit approximate factorization algorithm for block structured composite grids. Interfaces between blocks are treated by overlapping the grids and taking one layer of points from neighboring blocks. Turbulence is treated using the Baldwin-Barth one-equation turbulence model. High-lift applications presented for comparison with wind tunnel data include: a NACA 4412 airfoil with NACA 4415 flap, a GA(W)-1 airfoil with a 29 percent chord flap at 30 degree flap angle and two gap settings, and a GA(W)-1 airfoil

with 15 percent chord slat and 29 percent chord flap. Good agreement with experimental data is obtained for cases with fully attached flow or small regions of separated flow. For cases with extensive regions of flow separation, the thickness and extent of the separated regions are underpredicted. Author

An experimental program has been conducted to assess performance of a transport multielement airfoil at flight Reynolds numbers. The studies were performed at chord Reynolds numbers as high as 16 million in the NASA Langley Low Turbulence Pressure Tunnel. Sidewall boundary-layer control to enforce flow two dimensionality was provided via an endplate suction system. The basic airfoil was an 11.55 percent thick supercritical airfoil representative of the stall critical station of a new-generation transport aircraft wing. The multielement airfoil was configured as a three-element airfoil with slat and flap chord ratios of 14.48 percent and 30 percent respectively. Testing focused on the development of landing configurations with high maximum lift capability and the assessment of Reynolds and Mach number effects. Also assessed were high-lift performance effects due to devices such as drooped spoilers and trailing-edge wedges. The present experimental studies revealed significant effects on high-lift airfoil performance due to Reynolds and Mach number variations and favorable lift increments at approach angles of attack due to the use of drooped spoilers or trailing-edge wedges. However, no substantial improvements in maximum lift capability were identified. A recently developed high performance single-segment flap was also tested and results indicated considerable improvements in lift and drag performance over existing airfoils. Additionally, it was found that this new flap shape at its optimum rigging was less sensitive to Reynolds number variations than previous designs.

A viscous-inviscid interaction numerical method for incompressible flows over multi-element airfoils, which is an extension of the numerical method previously suggested for compressible attached or separated or even stalled flows over airfoils, is presented. The robust algorithms of the method are capable now to converge well for attached flows or massively separated flows, such as induced by slope discontinuities of airfoils or slats, or such as induced by stall. The viscous-inviscid approach introduces a self-adaptative viscous grid in both normal and streamwise directions along the displacement surfaces, with everywhere a streamwise grid-resolution of the same order as the separating boundary layer thicknesses, even at slat apexes, which is believed to eliminate any aleatory effect of numerical viscosity. The method is validated with respect to ONERA experiments, on the three-element RA16SC1 high-lift device, with the severe AMD slat-geometry. A realistic non-uniqueness of the separated flow solutions has been exhibited by the calculation method. A satisfactory agreement between theory and experiment is obtained, with the suggested 2-equation turbulence model.

HIGH-LIFT SYSTEM ANALYSIS METHOD USING UNSTRUCTURED MESHES
K. DECOCK *In* AGARD, High-Lift System Aerodynamics 20 p (SEE N94-18415 04-01) Sep. 1993
(AGARD-CP-515) Copyright Avail: CASI HC A03/MF A04

A 2D high-lift configuration analysis method is described. The flow model used is based on the Euler equations, discretized on unstructured meshes. The generation of the unstructured meshes is based on the principle of successive grid adaptation with respect to the geometry. This approach makes later extension towards fully integrated grid adaptation with respect to the solution straightforward. The main characteristics of the Euler solver are upwind flux-difference splitting of the convective part of the Euler equations (second-order accurate discretization in space) and four stage Runge Kutta local time stepping. Results obtained with this analysis method are shown for the NACA0012 airfoil and three-element airfoils. Conclusions are drawn. Author

A detailed description is presented of a computational method to predict the aerodynamic performance of mechanical high-lift systems. The Reynolds-averaged Navier-Stokes equations applicable to compressible, two-dimensional mean flow are solved using a cell-centered, finite-volume spatial discretization and an explicit multi-stage to time march to steady-state solutions. The governing mean-flow equations are solved in conjunction with a two-equation, high-Reynolds number k-epsilon turbulence model, this level of turbulence model sophistication being considered as the minimum required to enable an adequate resolution of the complex flow physics. The geometric complexity associated with practical multi-element airfoil configurations is addressed by adopting unconstructed computational grids. Results for the RAE 2822 transonic single-airfoil section are presented, comparing two near-wall treatments for the turbulence-transport equations. Thereafter, a detailed evaluation is presented of the predictive capability of the method, in its current form, by comparison with experimental data for the low-speed, high-lift NLR 7301 airfoil/trailing-edge flap configuration. Results are also presented for the SKF 1.1 airfoil/manoeuver flap configuration over a range of transonic flow conditions, from fully-subcritical flow to supercritical flow with shock-induced separation. The level of agreement between predictions and experiment is encouraging for the cases considered. However, it is concluded that improved modeling of the complex flow physics is required, with the lack of response of the current k-epsilon turbulence model to streamline curvature being a significant limitation on quantitative accuracy around maximum lift conditions. Similarly, procedures to automatically adapt the computational grid to the flow solution would improve predictions over the extended range of conditions associated with the practical operation of a mechanical high-lift system. At the DLR Institute for Design Aerodynamics current research in the area of high lift aerodynamics is directed towards the development of a computational analysis capability for high lift systems. The Navier-Stokes equations are solved with a multigrid method based on central spatial differencing and Runge-Kutta time stepping. Two particular problems are addressed in this paper. The first concerns the calculation of maximum lift for a single airfoil and a clean wing configuration. The accuracy of the basic

structured flow solver is investigated by comparing the results with experimental data for two test problems and several flow conditions. Emphasis is placed on the sensitivity of the computed solution associated with turbulence modeling. The second aspect dealt with in the present paper concerns the extension of the numerical method to multi-element airfoils. Both, the block-structured and the unstructured grid approach are investigated in order to explore their specific merits and limitations. Detailed comparisons of the structured and unstructured approach are presented for low Reynolds number laminar viscous flows around a single airfoil, and for the inviscid flow around a multi-element airfoil. Solution of the Reynolds averaged Navier-Stokes equations is obtained to simulate the flow field around a 13 percent thickness supercritical airfoil slat/blown-flap high-lift system. A stacked-C mesh topology is used in conjunction with the slat and the flap trailing edge streamlines and adapted to accurately locate the strong viscous flow regions. A previously modified PARC2D implicit ADI solver is employed whereby the multiply connected boundary value problem can be treated with a single computation zone. A modeled injection boundary condition was demonstrated to connect transient flap wake vortices downstream of the computational domain. The converged surface pressures and the values of the lift coefficient are compared with the wind tunnel data at M(infinity) = 0.17, Re = 3.4 M for momentum injection coefficients of C(mu) = 0.01 and C(mu) = 0.04, respectively. An extensive European wind tunnel research program on high lift systems has been carried out in the past few years within the framework of a GARTEUR Action Group. To provide a relevant and realistic case, permission was given by British Aerospace to use a section from the A-310 wing from which a 2D airfoil could be derived. A Deutsche Airbus 3D half model of the A-310 aircraft has been used for the 3D test and an airfoil representative of the 59 percent span section has been used for the 2D test. The wind tunnel test program carried out in the major European low speed wind tunnels (ONERA F1 in France, NLR HST and LST in Netherlands, RAE 5 m in UK) was complemented by a full scale flight test supported by Airbus Industries. A wide range of Reynolds numbers and Mach numbers has been covered by the test and a very comprehensive, well integrated and accurate body of data has been generated by this research program. After presenting GARTEUR the paper deals with the Reynolds number and the Mach number effects as well as the correlations between 2D and 3D data and between wind tunnel and flight test results. An experimental investigation into the use of half-model testing techniques specifically aimed at high-lift testing has been carried out in the 5 Metre Pressurized Wind Tunnel at the DRA, Farnborough. The aim of the program was to provide an assessment of the extent to which the measured characteristics of a high-lift model might be compromised by, in particular, the existence of a boundary layer on the reflection plane and how any penalties might be minimized. The results suggest that, provided care is taken with experimental technique, good agreement is possible on stall incidence as well as the absolute values of lift, drag and pitching moment. Author

Flight experiments are being conducted as part of a multiphased subsonic transport high-lift research program for correlation with wind-tunnel and computational results. The NASA Langley Transport Systems Research Vehicle (B737-100 aircraft) is used to obtain in-flight flow characteristics at full-scale Reynolds numbers to contribute to the understanding of 3-D high-lift, multi-element flows including attachment-line transition and relaminarization, confluent boundary-layer development, and flow separation characteristics. Flight test results of pressure distributions and skin friction measurements were obtained for a full-chord wing section including the slat, main-wing, and triple-slotted, Fowler flap elements. Test conditions included a range of flap deflections, chord Reynolds numbers (10 to 21 million), and Mach numbers (0.16 to 0.40). Pressure distributions were obtained at 144 chordwise locations of a wing section (53-percent wing span) using thin pressure belts over the slat, main-wing, and flap elements. Flow characteristics observed in the chordwise pressure distributions included leading-edge regions of high subsonic flows, leading-edge attachment-line locations, slat and main-wing cove-flow separation and reattachment, and trailing-edge flap separation. In addition to the pressure distributions, limited skin-friction measurements were made using Preston-tube probes. Preston-tube measurements on the slat upper surface suggested relaminarization of the turbulent flow introduced by the pressure belt on the slat leading-edge surface when the slat attachment line was laminar. Computational analysis of the in-flight pressure measurements using two-dimensional, viscous multielement methods modified with simple-sweep theory showed reasonable agreement. However, overprediction of the pressures on the flap elements suggests a need for better detailed measurements and improved modeling of confluent boundary layers as well as inclusion of three-dimensional viscous effects in the analysis. A quasi 3-dimensional method for analyzing the viscous steady subsonic flow over wings with flaps for high lift is briefly presented. The total iterative procedure combines a 3-dimensional inviscid lifting surface theory with a 2-dimensional surface-singularity method for analyzing multi-element airfoils in a curved basic flow field. This method also includes boundary layer calculations and a

model for rear separation. Also, small compressibility effects are accounted for by simple corrections, and ground effects are included by means of the reflected image technique. First attempts to validate the method by a few theory-experiment comparisons are reported. The results are encouraging but more experimental data are needed for a thorough validation. The computing time requirements of the method are modest. Author

A calculation method based on an interactive boundary-layer approach to multi-element airfoils and wings is described. For two-dimensional flows, the method is applied to three types of airfoil configurations with and without flap wells in order to demonstrate its applicability and accuracy to general high-lift configurations. This method, extensively tested for single airfoils as a function of shape, angle of attack, and Reynolds number, is shown here to apply equally well to multi-element airfoils. The calculation method is also applied to a wing and wing/flap configuration in order to demonstrate its promise for addressing three-dimensional flows. Preliminary results indicate that with further development, the method, as for multi-element airfoils, will also become a practical, accurate and efficient tool for multi-element wings. Author

A nonlinear unsteady vortex lattice scheme is used and flight dynamics equations are solved in order to predict the structure of the wakes and the instantaneous distribution of the aerodynamic loads on high-lift aircraft configurations, during general unsteady take-off maneuvers in ground effect. The numerical scheme here presented can treat an arbitrary number of mutually interfering lifting and moving control surfaces having arbitrary planform and camber. Wakes can be released in the flowfield from any of the sharp edges of the lifting surfaces, depending on their planform, aspect ratio and angle of attack, while the effects of the fuselage are ignored in the present formulation. Turbulent diffusion of the cores of the Rankine vortex filaments is regarded as a preeminent factor in a correct simulation of the development of unsteady interfering wakes. A vortex core diffusion model is used capable to deal even with the severe roll-up of the mutually interfering wakes developing close and impinging on the ground. Typical applications of the unsteady vortex lattice scheme are presented, aimed at illustrating the capabilities of the code. Author

The viscous-inviscid interaction transonic numerical method previously defined by the author for computing attached or separated flows over airfoils, including the deeply stalled flows, is extended into a new three-dimensional method for strongly separated flows over wings at high-lift and compressible speeds. The numerical nonlinearly implicit boundary layer technique (direct/inverse), the turbulent models, the grid generation and grid-adaption, the coupling and wake-equilibration algorithms, the inviscid full-potential schemes, are extended in three dimension, with approximation on the viscous equations (2.75D-local). New theoretical results are given on the singularities and characteristic cones of the fully three-dimensional boundary layer in inverse mode. A new 'Massive-separation 2.75D' extension of the 'Semi-inverse' algorithm of Le Balleur for coupling is given and detailed, together with its stability theory. Results are shown for 2D-stall, and for 3D separated flows over rectangular or swept wings, with satisfactory agreement between theory and experiment. A self-adaptation technique of the grid to the viscous effects is displayed. The results demonstrate that the viscous-inviscid interaction methods give a full access to the calculation of three-dimensional separation. Author (revised)

COMPARISON OF THE INTERACTIONS OF TWO AND THREE DIMENSIONAL TRANSVERSE JETS WITH A HYPERSONIC FREE STREAM
H. E. G. POWRIE, G. J. BALL, and R. A. EAST *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow 8 p (SEE N94-28003 07-34) Nov. 1993 Sponsored by Defence Research Agency
(AGARD-CP-534) Copyright Avail: CASI HC A02/MF A04

The interaction between a three dimensional (circular) sonic jet and a Mach 6.69 cross flow on a flat plate has been investigated experimentally. The results are compared with data from a two dimensional (slot) sonic jet in the same flow. In both cases the undisturbed flow on the plate is laminar. Heat transfer and oil flow visualization have been used to identify separation and reattachment within the flow field which, for the case of circular injection, has revealed a number of vortex cells in the region ahead of the jet. For the two dimensional interaction there is only evidence of one vortex pair in this region; however, a complex flow downstream of the slot jet has been observed. The influence of injectant gas type on the two dimensional interaction flow field is limited to a weak molecular weight dependence implied by separation length data. In contrast, for three dimensional injection, jet gas composition is found to have a marked effect on the size of the interaction flow field, as well as influencing surface heat transfer rate in the vicinity of the injector. This paper discusses experiments on side-jet control efficiency in the hypervelocity flow of a shock tunnel. The parameters of the test flow represent the Mach number, Reynolds number, velocity, and density of tropospheric hypervelocity flight. The experiments are carried out with a model, which is equipped with pyrotechnical charges, a settling chamber, laterally blowing jets, and a set of small accelerometers. The pyrotechnically supplied side-jets also are roughly adequate to those used in sound vehicles. Extensive jet gas diagnostics yield the parameters of the gas and the nozzle flow. The accelerometers incorporated in the model allow direct millisecond aerodynamic force measurement. To provide free-flight during the testing time, a fast-acting mounting support releases the model and grips it again when the test flow has passed the model. Using measured acceleration and Pitot pressure histories allows direct straightforward time-dependent evaluation of the aerodynamic coefficients. The procedure is insensitive to disturbances in the starting phase of the flow or moderate flow variations. The results quantify the force, which is produced by interaction of side-jets and ambient flow, and acts on the surface of the model. At the tropospheric hypervelocity conditions of our test, the interaction force on a flat plate substantially increases jet thrust. Moreover, the results quantify the time necessary to establish quasistationary flow for the actual test conditions. Author (revised)

Concentrated spanwise blowing over wings is a technique using mainly the secondary (= nonreactive) effects of a jet in crossflow, with the primary intention to generate and/or stabilize and control separated rolled-up leading edge vortex systems. This means an indirect application of a crossflow jet via triggering another crossflow phenomenon, the L.E. vortex. Based on the results of extensive experimental research, the merits and shortcomings of this technique are overviewed concerning aerodynamic performances, and stability and control aspects. The limits of aerodynamics efficiency are established on an empirical/theoretical basis and compared to experimental results. There is found a definite upper and lower boundary. The author's view is given concerning the practical (non-) applicability of this simple technique and the reasons for missing examples in operational aircraft are discussed via comparison to competitive approaches. Control of the separated flow over a delta wing using Tangential Leading-Edge Blowing has been investigated experimentally and computationally. Tangential Leading-Edge Blowing describes the injection of momentum into the cross flow plane of the wing by thin Coanda wall jets located at the point of cross flow separation. The concept is shown to be capable of generating significant asymmetry in the vortical flowfield, and hence a lateral control capability, up to very high angles of attack. The primary effects of jet blowing have been modeled using a Navier-Stokes computation with an algebraic turbulence model. Author

This paper deals with numerical studies made at AEROSPATIALE-MISSILES about aerodynamic interactions due to the use of pyrotechnical lateral force control. Calculations were performed in order to predict lateral jets interactions on two kinds of missiles: subsonic antitank and supersonic antimissile. In the subsonic case, Euler and Navier-Stokes calculations were compared on a missile body test case. Then, Euler code was applied to an antitank missile configuration, and missile spinning effects were assessed. In the supersonic case, jet stagnation temperature and jet species effects were studied on a surface-to-air missile. Author

This paper presents the techniques implemented as well as a collection of the results obtained during an experimentation leading to the S5 wind tunnel of ONERA in the case of a transverse jet of Mach number equal to 2, strongly heated, emerging in a perpendicular flow of the same Mach number. The flow is qualified by means of a miniature 5 hole probe, by thermocouples and tridirectional laser velocimetry. The effects of the temperature on the average and turbulent properties of the jet are discussed. Clear strioscopies are also presented. They highlight the strongly nonstationary nature of this interaction. Transl. by FLS

Experiments have been performed to assess the effectiveness of air-jet vortex generators as alternative to vanes in suppressing shock-induced separation. It is shown that a single jet inclined to the plane of the surface and skewed to the direction of the undisturbed stream produces a single strong vortex and can therefore be treated as the equivalent of a single vane. It follows that jets can be installed in arrays to correspond to arrays of vane vortex generators. A spanwise array of jets is shown to produce closely similar results to an array of co-rotating vane vortex generators of the type that has now been used in very many applications to suppress the effects of shock-induced separation. Air-jet vortex generators should therefore be equally effective in practice and may have significant inherent advantages for many applications. The vortex generators were effective for shock upstream Mach numbers up to and beyond 1.6. The maximum effectiveness occurred close to the generators but they remained reasonably effective for a range of shock positions of up to 50% chord. Some initial pointers are given on the influence of certain design parameters and on what considerations would apply in tailoring the jets to specific applications. Author

A good high angle of attack (AoA) behavior is a requisite for any new combat aircraft. In order to gain a better knowledge of the flow at high AoA, computation over the 'RAFALE A' has been conducted. The aircraft is in a full nose down controls configuration: low speed, low altitude, high AoA, and large control surfaces deflection. Moreover, slideslip is considered so as to assess the lateral behavior of the aircraft in this high AoA regime. The computational domain around the complete aircraft is discretized into an unstructured mesh and the flow is computed with a 3D inviscid (Euler) approach in finite elements. Aerodynamic coefficients have been analyzed together with the topology of the flow in these high AoA configurations. Results have been found to yield a promising agreement concerning the flow features (loss of weathercock stability at high AoA) although absolute values of coefficients are still beyond reach of this basic methodology. In an attempt to get insight into nonsymmetric flow as it can be

found experimentally at high AoA, a modification of the boundary conditions which create a source of vorticity has been implemented. This leads to the existence of large amplitude side forces agreeing with experiments. Author (revised)

SCALE EFFECTS ON AIRCRAFT AND WEAPON AERODYNAMICS [LES EFFETS D'ECHELLE ET L'AERODYNAMIQUE DES AERONEFS ET DES SYSTEMES D'ARMES]
A. BARRY HAINES (Aircraft Research Association Ltd., Bedford, England.) and A. D. YOUNG Jul. 1994 247 p
(AGARD-AG-323; ISBN-92-835-0754-1) Copyright Avail: CASI HC A11/MF A03

The present state of knowledge on scale effects at high lift and low speeds, at transonic speeds, and on aircraft drag are presented. In addition, scale effects in various important specific scale-sensitive areas such as forebody vortex flows, the flow in and near open cavities, the flow into an air intake, the flow over propellers, and on ice accretion simulation testing are discussed. The emphasis is on scale effects that have been observed in flight-tunnel comparisons for specific aircraft. It is concluded that much has been learned about scale effects; however, precise prediction can still be difficult. Twenty recommendations for further research are mentioned. This AGARDograph has been produced at the request of the Fluid Dynamics Panel of AGARD. Author

The wind tunnel continues to be the main instrument for providing experimental aerodynamic data to the aerospace industry and the aerodynamic researcher for the purpose of load and performance evaluation of theoretical results. In both cases, it is imperative that the user has confidence in the quality of the results, which means that he must have information of what accuracy to attach to the data. This report describes a practical approach for assessing the uncertainty of experimental measurements. Although it concentrates on aerodynamic references data, the approach presented can be used to report data and associated uncertainties for any other condition. The methodology described is designed to facilitate communications and to encourage professional and practical analyses of complex problems. The most recent accepted technical concepts have been included in the methodology. This report presents the results of a study by Working Group 15 of the AGARD Fluid Dynamics Panel. Author

A survey of the state of the art of Computational Aerodynamics based on the Euler Equations is presented. For the major Euler Codes that are currently in use in the NATO countries, numerical schemes, algorithms, grid generation, physical and numerical aspects, as well as a wide range of applications are included. Background material required for understanding the physics modelled by the Euler Equations is also presented. Areas of application concentrate on numerical simulation of external flows about aerospace vehicles. Internal flows and turbomachinery applications are not extensively treated but touched upon where considered appropriate. Author

Lecture notes for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Missile Aerodynamics' have been assembled in this report. The aim and scope of this course was to present the current state of the art on specific topics of tactical missile aerodynamics. Specifically, topics and methods covered include: Aeromechanical Design of Modern Missiles, Semi-empirical Predictive Tools, Lateral Jet Control, High Angle of Attack Aerodynamics, Analysis and Modelling of Missile Infrared Radiation, Navier-Stokes Computations for Complete Missile Configurations, and Navier-Stokes and Euler Computations for Supersonic Air Intakes. The material assembled in this report was prepared under the combined sponsorship of the AGARD Fluid Dynamics Panel, the Consultant and Exchange Program of AGARD, and the von Karman Institute (VKI) for Fluid Dynamics. For individual titles, see N95-14446 through N95-14452.

(AGARD-R-804) Copyright Avail: CASI HC A05/MF A03

The changes in the political and strategic situation in the world, especially in Europe, result in new kinds of military scenarios and in different approaches to well-known scenarios. In combination with technological advances and with new mathematical and physical solutions for system component design and for improvements in system performance this leads to a request for advanced and new types of missiles with corresponding design goals and criteria. From such more general demands associated with the overall system design new requirements for the aerodynamical and aeromechanical design goals can be derived in correspondence. Advanced experimental and theoretical tools support the project aerodynamicist in coping with these new problems. Examples for the demands for new missile types and for the new system requirements are given. The most important aeromechanical work packages in the design procedure of modern missiles are identified and methods to get solutions sufficient for qualitative answers in early project phases are presented.

This paper discusses the pros and cons of numerical, semiempirical, and empirical aeroprediction codes. It then summarizes many of the more popular approximate analytical methods used in state-of-the-art (SOTA) semiempirical aeroprediction codes. It also summarizes some recent new nonlinear semiempirical methods that allow more accurate calculation of static aerodynamics on complete missile configurations to higher angles of attack. Results of static aerodynamic calculations on complete missile configurations compared to wind tunnel data are shown for several configurations at various flight conditions. Calculations show the new nonlinear methods being far superior to some of the former linear technology when used at angles of attack greater than about 15 degrees.

The demand for continually increased performance of missiles and aircraft leads to considering flight at very high angles of attack where control is very difficult. This is mainly due to the shedding of asymmetric vortices from the forebody, producing side forces even at zero sideslip. The purpose of this paper is not to make a review of missile aerodynamics at high angle of attack, but to focus on an understanding of the phenomena which give rise to asymmetric vortices, from an experimental as well as a theoretical point of view. This paper discusses the application of Navier-Stokes computational methods to the prediction of the aerodynamics of missile configurations. The governing equations, turbulence models, and numerical approaches used to solve these equations are briefly described. The paper focuses mainly on aerodynamic coefficient prediction. Static and dynamic aerodynamic derivative prediction methods and applications are presented for axisymmetric and finned bodies and comparisons are made with experimental data. Results of validation studies are also presented for the purpose of demonstrating the accuracy as well as potential shortcomings of these techniques. The paper also discusses the application of Navier-Stokes methods in the prediction of base flow. Application of these techniques to unpowered, base bleed, and powered configurations is shown. The aim of this paper is to present how some CFD tools can be used to compute external and internal flowfields involved in the design of supersonic air-intakes. These tools help the designer to better understand flow phenomena, to determine favorable intake locations, and to predict air-intake performances such as pressure recovery and mass flow ratio. As supersonic intakes are mainly used on ramjet missiles, we limit this paper to ramjet air-intakes. After a brief overview of the existing types of air-intakes, we describe the way their performances are quantified. Then we present the CFD tools used to evaluate air-intake characteristics. Finally, selected applications of these tools demonstrate how a comprehensive study of air-intake may be achieved through CFD. Both external and internal flowfield computations are presented, which allows predictions of air-intake performances.

Wake turbulence is a misnomer. Turbulence implies a random process whereas the term 'wake turbulence' refers to the hazard posed to smaller airplanes by the ordered, rotational flow in the trailing vortex systems behind larger airplanes. This lecture begins by examining the relationship of aircraft size, geometry and operating conditions to the strength of an aircraft's trailing vortex system. Next, the velocity field initially induced close behind the generating airplane by its trailing vortex system is defined. This is followed by a discussion of the various ways in which a vortex system can dissipate and the many factors which affect the dissipation. In particular, the effects of atmospheric turbulence, ground proximity and vortex bursting on the ensuing behavior of the vortex system are considered. The paper continues with a study of the dynamics of an aircraft encountering the wake of a larger airplane. The degree to which an aircraft is threatened by a given vortex system of known characteristics is analyzed and the hazard posed by a given vortex system to a following aircraft quantified. Finally, the paper concludes with recommendations on possible ways to alleviate the safety and operational problems associated with wake turbulence. Author

A methodology for the solution of the 2-D and 3-D inverse inviscid subsonic flow problem is introduced. The proposed methodology handles the 2-D and axisymmetric rotational and the 3-D potential target pressure problem in a single-pass manner. The method is based on a potential function/stream function formulation where the physical space is mapped onto a natural one using the potential and stream function(s) as body-fitted coordinates. A novel procedure based on differential geometry and generalized tensor analysis arguments is employed to formulate the method in a modular way. The governing equations for the inverse problem are derived through the metrics compatibility condition on the natural space. Geometry is determined by integrating generalized Frenet equations along the natural coordinate lines. Rotationality, when present, is due to incoming (stagnation) thermodynamic quantities and/or preswirl gradients. The Clebsch formulation is, then, adopted to decompose the velocity field into a potential and a rotational part. To validate the method inverse calculation results are compared to results of direct 'reproduction' calculations. The design procedure of some optimized shapes is also presented. Part 1 of this lecture focuses on 2-D and axisymmetric inverse potential or rotational flow problems, while the fully 3-D inverse potential problem is considered in Part 2. Author

A potential function/stream function formulation is introduced for the solution of the fully 3-D inverse potential 'target pressure' problem. Potential function and two stream vectors are used as the independent natural coordinates, whilst the velocity magnitude, as well as, the aspect ratio and the cross-section angle of the elementary stream tubes are assumed to be the dependent ones. A novel procedure based on differential geometry is employed to formulate the method. The governing differential equations are derived by requiring the curvature tensor of the flat 3-D physical Euclidean space, expressed in terms of the curvilinear natural coordinates, to be zero. The resulting equations are discussed and investigated with particular emphasis to the existence and uniqueness of their solution. It is shown that the general 3-D inverse potential problem with target pressure boundary conditions only, is ill-posed accepting multiple solutions. This multiplicity is alleviated by considering elementary stream tubes with orthogonal cross-sections. The assumption of orthogonal stream surfaces reduces the number of dependent variables by one, simplifying the governing equations to an elliptic PDE, for the the velocity magnitude and to a second order ODE for the stream tube aspect ratio. The solution of these two equations provides the flow field. Geometry is determined independently by integrating Frenet equations along the natural coordinate lines, after the flow field has been calculated. The numerical implementation as well as validation test cases for the proposed inverse methodology are presented in the last part of the lecture. Author

This report presents the results of a study by Working Group 14 of the AGARD Fluid Dynamics Panel. The thirty nine test cases that are documented cover the subsonic, transonic, and supersonic flow regimes and five classes of geometries. Included in the five classes of geometries are: Two Dimensional Airfoils; Three Dimensional Wings, designed for predominantly attached flow conditions; Slender Bodies, typical of missile type configurations; Delta Wings, characterized by a conical type of vortex flow; and Complex Configurations, either in a geometrical sense or because of complicated flow interactions. The report is presented in two volumes. Volume 1 provides a review of the theoretical and experimental requirements, a general introduction, summary of the test cases and recommendations for the future. Volume 2 contains detailed information on the test cases. Relevant data has been compiled on floppy disks. For individual titles, see N95-17847 through N95-17885.

The tests detailed in this submission were carried out by the former British Aircraft Corporation in support of the National High Lift Programme. This Programme was a collaborative project between the Royal Aerospace Establishment Farnborough (now part of the the DRA) and the aircraft industry with the aim of increasing the understanding and knowledge of all aspects of high-lift systems, and to provide a fund of data which would benefit the design of future transport aircraft. Wind-Tunnel tests were carried out on four models: (1) A 3-D half model (RAE); (2) a swept panel wing (HSA Hatfield); (3) a quasi-2D (end-plate) model (BAC Weybridge); and (4) a 2D model (BAC Weybridge). BAC Warton also carried out structural analyses on various leading-edge and trailing-edge devices. The present cases are results from the 2D tests which covered investigations into two leading-edge and two trailing-edge devices. The model had a supercritical aerofoil section, a chord of 0.7635m, and was mounted between turnables in the floor and roof of the BAC 3.96m x 2.74m low-speed wind-tunnel. Two-dimensional conditions were maintained by local suction around the wing/wall junctions. Surface pressures were measured on all the components of the wing, at two spanwise stations, one near the tunnel centerline, and one near the roof. These pressures were integrated to give overall lift, drag and pitching moment coefficients. A pilot/static transverse through the wake provided the total momentum deficit. Traverses perpendicular to the wing surface at various chordwise locations provided information on wake and boundary layer development and interaction. Flow visualization was provided by tufting of the wing surfaces. Author

INVESTIGATION OF THE FLOW OVER A SERIES OF 14 PERCENT-THICK SUPERCRITICAL AEROFOILS WITH SIGNIFICANT REAR CAMBER
P. R. ASHILL *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 13 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The experiments described in this submission were performed on various airfoil sections, all of 14 percent thickness/chord ratio and with significant rear camber. The main aim was to obtain an improved understanding of viscous effects on flows over airfoils with severe adverse pressure gradients. Such gradients can be found at the rear airfoils with significant rear camber and at the foot of shock waves. The tests were performed in the 8ft x 8ft Pressurized, Subsonic/Supersonic Wind Tunnel at the Defense Research Agency (DRA, formerly the Royal Aerospace Establishment) Bedford between November 1976 and February 1982. This wind tunnel has solid walls and, since the airfoil chord to tunnel height is relatively large (0.26), the data are strictly not correctable. This was recognized from the outset, the main concern of the investigation being studying flows rather than performing tests on a prescribed shape. However, the wall boundary conditions are well defined and so the data may be useful for validating CFD codes which include allowance for the wind-tunnel walls. In addition, measurements were made of the static pressures on the roof and floor of the working section, providing an independent check on the accuracy of the representation of the walls in any CFD method. Despite the caveat above about correctability, it is believed that the cases presented having weak shock waves may be used to assess free-air calculation methods provided that allowance is made in the calculation for wall-induced camber. Cases suitable for such work are highlighted in Section 6.2 where details are also given of the camber correction. Author

SURFACE PRESSURE AND WAKE DRAG MEASUREMENTS ON THE BOEING A4 AIRFOIL IN THE IAR 1.5X1.5M WIND TUNNEL FACILITY
D. J. JONES and Y. NISHIMURA *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 10 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A02/MF A06

This 10.2 percent maximum thickness to chord airfoil has become a standard airfoil for Boeing wind tunnel tests in the IAR 1.5 X 1.5m facility. In order to study wall constraint effects, several different chord lengths have been used in the narrow span (38.1 cm) IAR facility and a 30.5 cm chord model was tested in the 1.5 wide facility. The latter data from the wide span facility are presented here. This data has a small sidewall correction while the upper and lower walls are accounted for using Mokry's wall correction procedures. Transition was fixed at 10 percent and all runs were made at a chord Reynolds number of 14 million. The tests were carried out in June-July, 1991. Author

2-D AILERON EFFECTIVENESS STUDY
V. D. CHIN, C. J. DOMINIK, F. T. LYNCH, and D. L. RODRIGUEZ *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 20 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The experimental data described in this contribution were obtained in the IAR High Reynolds Number 60 x 15 (1.5m x 0.38m) Two-Dimensional Test Facility. The purpose of the experiment was to investigate the effects of Reynolds number and Mach number on aileron effectiveness and to evaluate effectiveness of viscous scaling techniques that attempt to simulate flow at higher Reynolds numbers. The advent of the modern transport wing has prompted a renewed interest in the transonic characteristics of ailerons. In addition to their traditional role of lateral (roll) control, aileron are used for wing load alleviation and to improve cruise performance through the 'drooped aileron' concept. An understanding of the prevailing flow physics which limit the transonic performance of ailerons is necessary for the successful design of a control system that satisfies the multi-role requirements of the aileron. Results showed a linear variation of lift for upward trailing edge deflections but a highly nonlinear variation for downward deflections. This nonlinear behavior, equivalent to a loss in aileron effectiveness, became worse at higher angles of attack and higher Mach numbers. In addition, the viscous scaling technique that was used at lower Reynolds numbers was found to be inadequate for modeling flow at higher Reynolds numbers. The data acquired from this test were for a series of aileron deflections varying from -5 to +5 deg at Mach numbers of 0.717 and 0.746 and chord Reynolds numbers of 5, 15, and 25 million. The following types of data were obtained:

airfoil surface pressure distributions; wake drag, which was determined by wake transversing probes; lift and drag forces and pitching moment, which were determined by force balance readings and surface pressure integrations; and floor and ceiling pressure distributions, which were used to compute wall interference effects. One of the difficulties in wind tunnel testing is accounting for the effects of wall interference to reinterpret the data for 'free air' conditions. Corrections for interference effects of the floor and ceiling and for the wall sidewall boundary layer effects were applied to the data. The data are available corrected for floor and ceiling effects, and corrected for both floor and ceiling interference and sidewall boundary layer effects. Author

INVESTIGATION OF AN NLF(1)-0416 AIRFOIL IN COMPRESSIBLE SUBSONIC FLOW

P. GUNTERMANN and G. DIETZ *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 10 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A02/MF A06

The data presented in this contribution were obtained in the 40 x 40 sq cm Transonic Wind Tunnel at the Aerodynamisches Institut of the RWTH Aachen within the research program 'Entwicklung von Berechnungsverfahren fur Probleme der Stromungsmechanik' sponsored by the Stiftung Volkswagenwerk. The aim of the experimental part of the research program was to investigate the influence of compressibility on the location of transition. For this purpose a natural-laminar-flow airfoil NLF (1)-0416, designed for incompressible flow, was investigated. Starting with incompressible free stream conditions the Mach number was increased until transonic flow was obtained. The experiments on the NLF(1)-0416 should provide aerodynamical forces such as lift and drag and data concerning the location and the underlying physical mechanism of transition. Therefore different measuring techniques, e.g. liquid crystal coating and multi-sensor hot-film technique, were tested. To verify the existence of a laminar separation bubble the topology of the boundary layer was visualized. Regarding the different turbulence levels there is a good agreement of the experimental results with those obtained at NASA-Langley, which are available up to Mach numbers of 0.4. Numerical results correspond to the experiments at higher Mach numbers too. Experiments were carried out to get information about the influence of small disturbances of the profile surface on the pressure distribution, the drag, and the location of transition. In continuation of this research a wind tunnel model with adjustable geometry of its upper surface was developed and manufactured. The influence of small surface variations on the location of transition or separation will be investigated experimentally, but these tests are not part of the presented data set. Author

TWO-DIMENSIONAL 16.5 PERCENT THICK SUPERCRITICAL AIRFOIL NLR 7301

S. O. T. H. HAN *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 11 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

This thick supercritical airfoil designed for a lift-coefficient of 0.595 at a Mach number of 0.721 (potential flow conditions) was an early NLR design of a supercritical airfoil made in 1973. The airfoil was designed with the hodograph method and has a rather blunt nose with a roof-top type pressure distribution. A typical other feature of this airfoil is that it is highly rear loaded, both on the upper surface and on the lower surface. Because of this rear loading, the airfoil is close to trailing edge separation on the upper surface and separation in the cove region around 70% chord at the lower surface. Tests have been made originally in the NLR (Transonic) Pilot Tunnel at a Reynolds number of 2.2 million (the design condition). The results of these tests have been included in AGARDograph AR-138. At about the same time test were made in the Compressible Flow Facility CFD) of Lockheed (Georgia, USA) for the Reynolds number of 10, 20 and 30 million. In the eighties, when more advanced computer codes became available that could cope with airfoils that experienced a limited extent of separation, there was an urgent need for reliable data to validate the computer codes for these conditions. Also, the problem of scaling (low Reynolds number) wind tunnel tests to (the much higher) flight Reynolds numbers raised (again) considerably interest. For both reasons it was decided to repeat the original NLR 7301 experiments on a larger two-dimensional model in the large transonic wind tunnel HST of NLR. The tests covered the low speed and transonic speed regimes whereas part of the measurements was performed at constant lift for range of Reynolds numbers of study the indirect Reynolds number effects in more detail. LOW-SPEED SURFACE PRESSURE AND BOUNDARY LAYER MEASUREMENT DATA FOR THE NLR 7301 AIRFOIL SECTION WITH TRAILING EDGE FLAP

B. VANDENBERG and J. H. M. GOODEN *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 12 p (SEE N95-17846 04-02) Aug. 1994

Test data are given for a two-dimensional wing flap configuration, which has been so designed that nowhere flow separations occur, apart from a small laminar separation bubble on the wing nose. The 32% chord trailing edge flap is deflected 20 deg. Two widths of the gap between wing and flap have been applied, with mixing of the wing wake and flap boundary layer occurring with the smaller gap. The experiment has been carried out at a Reynolds number Re, c = 2.51 * E6 and a Mach number of about Ma = 0.185. The measurements comprise surface pressure data, from which lift and pitching moment coefficients were calculated, at various angles of attack from zero up to beyond stall. At three angles of attack the drag has been determined from wake traverses. At these angles mean flow measurements in the boundary layer and wake have been executed at 16 stations. In addition turbulence data were obtained at 5 stations in the wing wake above the flap. Surface flow visualization data are also available. Author

DATA FROM THE GARTEUR (AD) ACTION GROUP 02 AIRFOIL CAST 7/DOA1 EXPERIMENTS

A. MIGNOSI, J. P. ARCHAMBAUD, and E. STANEWSKY (Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Goettingen, Germany.) *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 12 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

In order to gain a better understanding of the various forms and the magnitude of wind tunnel interferences that may arise in two-dimensional testing and to find improved methods of correction, a GARTEur Action Group was formed in 1979 with the primary objectives of (1) comparing test results obtained with one airfoil (CAST 7) in a number of facilities in order to assess wall interference in the individual tunnels and to assess the accuracy of correction methods currently used and (2) evaluating three-dimensional interference effects associated with the side wall boundary layer. The wind tunnels considered consisted of five conventional tunnels with either slotted or perforated test section walls and two adaptive wall wind tunnels. Based on a comparison of the results from these tunnels, it was concluded that for these

two-dimensional airfoil tests the freestream conditions, Mach number and angle of attack, were generally predicted with an accuracy of delta M infinity = plus or minus 0.002 and delta alpha = plus or minus 0.1 deg to plus or minus 0.05 deg, respectively, and the lift and drag coefficients with an accuracy of delta C(sub L) = plus or minus 0.015 and delta C(sub D) = plus or minus 0.0003 deg, respectively. For the adaptive wall wind tunnel T2 of ONERA/CERT the accuracy in freestream conditions was determined to be delta M infinity = plus or minus 0.001 and delta alpha = plus or minus 0.03 deg. Due to their relatively high accuracy, only the ONERA T2 adaptive wall tests are considered hereafter. The data, obtained with well defined boundary conditions, are believed to be the most suitable for CFD - assessment.

OAT15A AIRFOIL DATA

A. M. RODDE and J. P. ARCHAMBAUD *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 13 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The OAT15A airfoil is a supercritical airfoil for transport aircraft designed a few years ago within the framework of an ONERA/Aerospatiale joint programme devoted to the study of various designs. The design point is M = 0.73, C(sub L) = 0.65 and the thickness to chord ratio of the airfoil is 12.3 percent. The tests which were performed in the ONERA/CERT T2 wind tunnel were devoted to the Reynolds number effects on the airfoil performance. These effects were investigated within the range 3-20 10(exp 6) taking advantage of the cryogenic capability of the tunnel. The adaptive top and bottom walls of the tunnel give quasi free air conditions. However some sidewall effects are present and are taken into account in the correction procedure. Tests performed on another model in the S3MA wind tunnel with perforated top and bottom walls show good agreement with the T2 tests which give more confidence concerning the quality of the data. The proposed test cases concern mainly pressure distributions for various Reynolds numbers with fixed transition. However for a selected number of test cases boundary layer measurements with an external probe and LDV flow field data are also given. The set of data can be used for different purposes: (1) computer code capability for the prediction of Reynolds number effect; and (2) detailed 2D computer code assessment.

A SUPERCRITICAL AIRFOIL EXPERIMENT

GEORGE G. MATEER, H. LEE SEEGMILLER, LAWRENCE A. HAND, and JOACHIM SZODRUCH (Messerschmitt-Boelkow-Blohm G.m.b.H., Bremen, Germany.) *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 12 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The purpose of this investigation is to provide a comprehensive data base for the validation of numerical simulations. The initial results of the study (single angle of attack) were presented in ref. 1, where the effects of various parameters and the adequacies of selected turbulence models were discussed. The objective of the present paper is to provide a tabulation of the experimental data. The data were obtained in the two-dimensional, transonic flowfield surrounding a supercritical airfoil. A variety of flows were studied in which the boundary layer at the trailing edge of the model was either attached or separated. Unsteady flows were avoided by controlling the Mach number and angle of attack. Surface pressures were measured on both the model and wind tunnel walls, and the flowfield surrounding the model was documented using a laser Doppler velocimeter (LDV). Although wall interference could not be completely eliminated, its effect was minimized by employing the following techniques. Sidewall boundary layers were reduced by aspiration, and upper and lower walls were contoured to accommodate the flow around the model and the boundary-layer growth on the tunnel walls. A data base with minimal interference from a tunnel with solid walls provides an ideal basis for evaluating the development of codes for the transonic speed range because the codes can include the wall boundary conditions more precisely than interference corrections can be made to the data sets.

TWO-DIMENSIONAL HIGH-LIFT AIRFOIL DATA FOR CFD CODE VALIDATION

G. W. BRUNE *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 13 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The purpose of the experimental investigation summarized below was to provide a complete data set for the validation of two-dimensional multi-element airfoil computer codes. The airfoil model used for this investigation features four elements including a double slotted trailing edge flap and a slotted leading edge device representing a section of a transport wing in high-lift configuration with take-off flap setting. The leading edge flap was tested in a nonoptimum setting in order to produce a thick confluent boundary layer on the upper airfoil surface. In this wind tunnel experiment, all data were measured on a single high-lift airfoil configuration with a fixed flap setting at one tunnel freestream condition. Emphasis was placed on the acquisition of a few high quality airfoil data with many repeat runs and redundant measurements. Measured data comprise airfoil lift, drag, pitching moment, surface pressures, mean velocity profiles and Reynolds stresses of the confluent boundary layer. The data was obtained in the Boeing Research Wind Tunnel located in Seattle at 0.11 Mach number and 1.55 million Reynolds number based on tunnel freestream velocity and a flaps-up airfoil chord of 0.6096 m (2 ft). Care was taken to achieve a close approximation to two-dimensional flow by means of turntable and tunnel side wall blowing. Two-dimensional flow was verified by comparing boundary layer mean velocity and turbulence profiles at several spanwise stations, and by various surface flow visualizations methods. In addition, lift curves from balance measurements and an integration of surface pressures were compared. Confluent boundary layer measurements were conducted employing a Pitot probe and hot wires. Probes were mounted on a mechanical traverser designed to minimize disturbances of overall airfoil circulation and of the local flow at the measuring station. Author

MEASUREMENTS OF THE FLOW OVER A LOW ASPECT-RATIO WING IN THE MACH NUMBER RANGE 0.6 TO 0.87 FOR THE PURPOSE OF VALIDATION OF COMPUTATIONAL METHODS. PART 1: WING DESIGN, MODEL CONSTRUCTION, SURFACE FLOW. PART 2: MEAN FLOW IN THE BOUNDARY LAYER AND WAKE, 4 TEST CASES

M. C. P. FIRMIN and M. A. MCDONALD *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 18 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The experiments presented should improve the understanding of the flow over a wing as the speed is increased towards the buffet and separation boundaries. These boundaries limit the flight envelopes of both military and civil aircraft, and the measurements reported will allow Computational Fluid Dynamic (CFD) methods for viscous flow to be validated. The measurements are reported in two documents (Parts 1 & 2) giving detailed measurements of the subsonic free stream flow over a low aspect-ratio wing (RAE Model 2155) at conditions where the boundary layers are subjected to severe adverse pressure gradients. Part 1 provides measurements of pressure distributions on both the wing and on the tunnel walls for a wide range of Mach numbers and lift coefficients, as well as of wing surface skin friction and surface flow direction measurements for four test cases, while Part 2 contains detailed mean flow measurements within the shear layers. For this detailed study, the same four test cases have been used, as presented in Part 1. They were chosen to provide examples of flows with severe adverse pressure gradients, including those with shock waves, and leading in some cases to separation. Author

DETAILED STUDY AT SUPERSONIC SPEEDS OF THE FLOW AROUND DELTA WINGS
M. J. SIMMONS *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 17 p (SEE N95-17846 04-02) Aug. 1994

The tests described in this submission were made on two half-models of delta-wing/body configuration suitable for supersonic combat aircraft. The aim of the program of work was to improve the understanding of supersonic flows over wing with rounded leading edges. The reason for choosing the large half-model design were: (1) the attainment of high chordal Reynolds numbers; (2) the facility to make detailed flow measurements; and (3) the ability to manufacture the large wing to the desired model accuracy with conventional machine tolerances. The last requirement is particularly important in the highly-curved region of the leading edge which controls the development of transonic flows on the upper surface. Both wings are of the same quasi-delta planform of 60 leading edge sweep and thickness form of 4% thickness/chord ratio but with differing camber distributions. Wing A has a complex camber surface with camber in both spanwise and streamwise planes. Wing C has an umcambered symmetrical section and was used as a datum case for the study. The only design constraint on model size was the need to ensure that the flow over the wing was not disturbed by shock-wave reflections from the solid walls of the tunnel. The tests were performed in the 8ft x 8ft Pressurized, Subsonic/Supersonic Wind Tunnel at the Defense Research Agency (DRA Aerospace Division, formerly the Royal Aerospace Establishment) Bedford in July 1985.

PRESSURE DISTRIBUTIONS ON RESEARCH WING W4 MOUNTED ON AN AXISYMMETRIC BODY
J. L. FULKER *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 12 p (SEE N95-17846 04-02) Aug. 1994

The experiments described in this submission were performed on a wing-body configuration suitable for a civil transport aircraft. When the wing was designed (1972) it was recognized that, in order to achieve an advance in technology, a significant increase in rear loading would be required compared to that of earlier designs. As a consequence, the boundary layer conditions close to the trailing edge on the upper surface were expected to be more adverse than in previous designs. This requirement led to the need for a high test Reynolds number, which was achieved by testing a large half model in the Defense Research Agency (DRA) 8ft x 8ft Wind Tunnel at Reynolds numbers, based on geometric mean chord, of up to 15 x 10(exp 6). Complementary tests were also performed on a smaller complete model in order to provide an accurate assessment of the drag characteristics of the wing. The wing was designed to have a weak shock wave near mid chord on the upper surface at the cruise condition (C(sub L) = 0.32, M = 0.78). The overall aims of the investigation were to obtain an improved understanding of the behavior of the flow over wings of this type over a wide range of subsonic Mach numbers and Reynolds numbers. The tests were performed during 1977 on the complete model and 1978 on the half model. The wind tunnel has solid walls, and since the models are relatively large, the data are strictly not correctable. However, the wall boundary conditions are well defined and so the data may be useful for validating CFD codes which include allowance for the wind-tunnel walls. In addition measurements were made on the static pressures on the roof and floor of the working section, providing an independent check on the accuracy of the representation of the walls in any CFD method.

A swept wing with symmetrical sections was originally created to serve two purposes. First, the surface generator used for data definition was under development for aerodynamic design and optimization. The wing created was intended therefore to be a selected case of a whole family of configurations obtained by variation of the input parameters. Aerodynamic design and optimization strategies call for such variations. Second, CFD code development needs both accurate test case geometries as well as experimental results from wind tunnels. The latter usually suffer from corrections which still might suit practical purposes of measuring aerodynamic coefficients but fall short of the requirement to define the flow conditions to the same accuracy as geometrical boundaries are known. Using the generator software, a compromise was chosen by including the closed wind tunnel wall geometry as a channel boundary surrounding an aerodynamic component. In order to also avoid model support problems, a wing half model mounted on and including a splitter plate was used as 'configuration.' Geometry of the flow boundaries was completely defined through the simple rectangular channel geometry completed by chosen inlet and exit planes. Flow data were required at these planes to formulate a boundary value problem for CFD. In a workshop to compare CFD results with the first test case experiment (1986), partners had obtained and used a computer code to generate the wing and the wind tunnel boundary conditions, along with the absolutely necessary parameters to formulate fluid dynamic boundary conditions for the Navier-Stokes equations. This software is a simplified version of the geometry generator for aerospace configurations and CFD grid generation which has since been further developed as an industrial tool for design aerodynamics. The experiment and the refined half-model technique was published and the results of the workshop, comparing numerical results, have been summarized. Based on these results we may conclude that for CFD this test case turns out to be a complicated one basically because of the observed viscous flow phenomena on the wing. On the other hand, the definition of the complete boundary value problem makes the case rather unique and, with the help of generator software and experimental data, easy to implement for CFD validation. The workshop software and experimental results for surface pressure distributions is made available in one package.

This test was initiated to provide validation data on low aspect ratio wings at transonic speeds. The test was conducted so that the data obtained would be useful in the validation of codes, and all boundary condition data required would be measured as part of the test. During the conduct of the test, the measured quantities were checked for repeatability, and when the data would not repeat, the cause was tracked down and either eliminated or included in the measurement uncertainty. The accuracy of the data was in the end limited by wall imperfections of the wind tunnel in which the test was run. Derived from text

WIND TUNNEL INVESTIGATIONS OF THE APPEARANCE OF SHOCKS IN THE WINDWARD REGION OF BODIES WITH CIRCULAR CROSS SECTION AT ANGLE OF ATTACK
H. ESCH *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 16 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

Originally the model was designed to investigate differences in the interference of fuselage and control surfaces attached to bodies of circular and rectangular cross sections. During the test it was found difficult to define the interference since the reference configuration, the isolated body without controls, showed some disturbances in the pressure distribution at certain combinations of Mach number and angle of attack. These disturbances are connected with the appearance of shock waves on the windward side of isolated circular bodies. By checking schlieren pictures made during earlier test series of missiles the range could be defined in which this type of shock occurs. Pressure distribution measurements were made in order to find an explanation for the formation of the shocks and their bending into the windward region. It is believed that three conditions must be fulfilled: (1) Crossflow Mach number must be high enough that a shock forms in front of the wedge-like primary separation. (2) The primary separation line must move towards the windward side of the body. As a result the local Mach number normal to the separation line decreases, and eventually the shock detaches - if the crossflow Mach number is not too high. (3) When the local surface Mach number normal to the body axis is less than one, the disturbances propagates towards the windward region of the body. In some cases this type of disturbance may lead to confusion especially when there are not enough pressure taps: in the pressure distribution one finds only one or two peaks and from this, one cannot identify the shock trace. The model is extremely simple and thus the generation of a grid should not be too expensive. The data are considered valuable for CFD validation but on the other hand CFD should be useful to get more information of the outer flow field and further insight into this more fundamental flow phenomenon. Force, moment, flow field, and pressure measurements (steady and unsteady) were carried out on an ogive-nosed circular cylinder body with a smooth surface. The tests were performed in the two open jet low speed wind tunnels of the DLR in Gottingen (NWG, test section size 3 m x 3 m) and in Braunschweig (NWB, test section size 2.8 m x 3.25 m). A body diameter of D = 200 mm was chosen to achieve Reynolds numbers as high as possible at the maximum speed in these tunnels. The tests comprise angles of attack from 0 to 90 deg and Reynolds numbers of 2.5 x 10(exp 5), 3.7 x 10(exp 5), and 7.7 x 10(exp 5) (based on body diameter and freestream conditions). For six angles of attack between 20 and 70 deg the dependence on different roll positions of the body was systematically investigated with a complete coverage of 360 deg. In some cases the turbulence level of the freestream was varied. The body vortices were visualized in a water towing tank using hydrogen bubbles and in the wind tunnel with the aid of smoke and a laser light sheet. Derived from text

Boundary-layer separation occurring on a missile body at moderate or high angle of incidence leads to the formation of well organized vortical structures, especially at supersonic flight Mach numbers. Even though a certain number of experimental results are available for this type of flow, none of the published data provide complete information for a supersonic flow. A experimental study of the flowfield around a 3 caliber tangent ogive-cylinder body in a supersonic flow has been carried out to provide a consistent description of the flow. This experiment includes oil flow visualizations, primary separation line determination, surface pressure measurements and five hole pressure probe surveys for a Mach number of 2 and an angle of incidence varying from 0 to 20 deg. Results are obtained for a natural and fixed transition. Author

The windtunnel tests carried out on this model resulted from an international co-operation that involved the aeronautical laboratories AFWAL (US), DLR (Germany), FFA (Sweden), NLR (The Netherlands) and the Universities of Braunschweig (Germany) and Delft (The Netherlands). It was the basic aim of these measurements to provide detailed pressure and flow field data on a 65 deg delta wing configuration of a generic shape for the validation of CFD methods, notably Euler methods. For this reason one of the basic configurations had a sharp leading edge. However, there was also considerable interest for configurations with more realistic features and therefore other configurations were added. These featured a wing with a smaller sweep angle (55 instead of 65 deg), a rounded instead of a sharp leading edge shape, a drooped leading edge and the addition of a canard wing. The windtunnel tests were made in different wind tunnels with different models. They covered a large range of flow conditions and measuring techniques (including force, pressure and flow field measurements). The test case to be described here covers only the force and pressure measurements as carried out at NLR in the transonic windtunnel HST and the supersonic windtunnel SST. The measurements executed at DLR, including flow field measurements, can be found in case D-4. Author

A detailed study has been made on the flow around a 75 sweep angle delta wing to provide reference material or numerical codes. Experiments were carried out in the F2 wind tunnel of the ONERA Le Fauga - Mauzac Centre. Firstly an examination of the surface flow properties was carried out using surface pressure measurements an surface flow visualizations with a viscous coating. The angle of incidence was varied between 5 and 30 deg and the upstream velocity between 10 and 75 m/s. Secondly,the aerodynamic field was characterized by means of laser tomography visualizations and surveys with a two component laser Doppler velocimeter system. Mean and fluctuating velocity fields were determined in several vertical planes normal to the wind tunnel longitudinal axis. These measurements were carried out for an

angle of incidence of 20 deg and for two values of the upstream velocity (24 m/s and 40 m/s). Author

Data was obtained from a low-speed wind-tunnel experiment carried out on a sharp-edged 76/60-deg double-delta wing. The objective of the investigation was to generate data on the vortex interaction downstream of the strake-wing leading-edge kink of a double-delta wing. An oil-flow and laserlight-sheet technique was used to visualize the flow on and off the surface of the wing. Balance measurements were performed to determine the forces and moments acting on the wing. In addition, the pressure on the upper surface of the wing was measured at several wing chordwise stations. Using a thin five-hole probe, the flowfield over the wing panel was surveyed in detail for an incidence of 20 deg. The data provide information on the interaction process of the wing and strake vortex as well as the development of the secondary separation downstream of the leading-edge kink. Author

INVESTIGATION OF THE FLOW DEVELOPMENT ON A HIGHLY SWEPT CANARD/WING RESEARCH MODEL WITH SEGMENTED LEADING- AND TRAILING-EDGE FLAPS
D. STANNILAND *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 18 p (SEE N95-17846 04-02) Aug. 1994
(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The results included in this submission are drawn from the extensive testing which has been carried out on a simple canard/wing research model with a low aspect ratio (2.3), highly swept (58 deg) wing with leading- and trailing-edge flaps. The purpose of these tests was to improve the understanding of the flow development of this class of configuration, to validate the CFD method and philosophy used for the wing design and to provide and extensive data base of pressure data on a precisely specified model geometry for the validation of CFD methods which are capable of handling more complex geometries. The wing was designed using an FP wing/body code, aiming for attached flow at a high subsonic maneuver design point. This results in a highly cambered and twisted wing with a complex flow breakdown on the upper surface. The use of a segmented leading-edge flap means that the vortical flow develops as a series of part-span vortices, even at a constant flap setting with the gaps between the flap segments sealed. The model has been tested in the ARA 9ft by 8ft Transonic Wind Tunnel over the period 1985 - 1992 to investigate: (1) the effect of a canard, including variation in its position and setting angle; (2) the effect of alternative leading- and trailing-edge flap angles, including both positive and negative settings, although the model is capable of being tested with graded settings across the span (this option has not been investigated to date); (3) a three surface configuration (canard/wing/tailplane); and (4) a blended wing/body derivative of the model, using the existing outer wing and canard designs. Obviously these tests provide an extensive data base and the results included here comprise the datum wing without flap deflection, both with and without a canard. Author

The contribution describes wind tunnel measurements of aerodynamic forces, pressure distributions and surface visualization for the FALKE model. FALKE is a model of the US-Orbiter in the scale 1:5.427. The test results taken in the subsonic wind tunnel DNW enable validation of computational methods for reentry vehicles in landing conditions at high Reynolds numbers, where strong vortical flow occurs on the upper side of the configuration. The demand for even more economic jet engines requires extensive experimental investigations of the complete flow field around wing-body-engine-pylon (WBEP) configurations. The engine can be simulated best by pressure-driven devices, so-called Turbine-Powered Simulators (TPS). Though they have been applied for about 20 years, very few nacelle surface pressure measurements were carried out up to now. The reason is seen in the small size of the engine and in the poor theoretical capabilities in the past. Nowadays, WBEP configurations are handled by the Euler code, but experimental validation is required. One pre-step is the experimental investigation of the isolated nacelle which is presented here. The data presented in this contribution were obtained in the NASA Langley 16-Foot Transonic Tunnel. Multiple test entries were completed and the results have been completely reported in five NASA reports. The objective of the initial investigation was to

determine the effect of empennage (tail) interference on the drag characteristics of an axisymmetric model with a single engine fighter aft-end with convergent divergent nozzles. Two nozzle power settings, dry and maximum afterburning, were investigated. Several empennage arrangements and afterbody modifications were investigated during the initial investigation. Subsequent investigations were used to determine the effects of other model variables including tail incidence, tail span, and nozzle shape. For the final investigation, extensive surface pressure instrumentation was added to the model in order to develop and understanding of the flow interactions associated with afterbody/empennage integration and also to provide data for code validation. Extensive computational analysis has been conducted on the staggered empennage configuration at a Mach number of 0.6 utilizing a three-dimensional Navier Stokes code. Most of the investigations were conducted at Mach numbers from 0.60 to 1.20 and at ratios of jet total pressure to free stream static pressure (nozzle pressure ratio) from 0.1 (jet off) to 8.0. Some angle of attack variation was obtained at jet off conditions. Author

This test was originally conducted to determine the effects of several empennage and afterbody parameters on the aft-end aerodynamic characteristics of a twin-engine fighter-type configuration. Model variables were as follows: horizontal tail axial location and incidence, vertical tail axial location and configuration (twin-vs single-tail arrangements), tail booms, and nozzle power setting. Jet propulsion was simulated by exhausting high-pressure, cold-flow air from the nozzles. Following a successful test conducted on a single engine nacelle model to validate a CFD code, this model was chosen to be instrumented with pressure taps on the afterbody and nozzles and used as a follow-on test, providing a more complex geometry for the CFD code validation. A more limited test matrix was run to collect the pressure data, employing only the twin-tail configuration and varying only the horizontal and vertical tail locations. Mach number was varied from 0.6 to 1.2. Nozzle pressure ratio was varied from jet-off to 8. Angle-of-attack varied from 0 to 8 deg. Author

The transitional flight characteristics of a geometrically simplified Short Take-Off Vertical Landing (STOVL) aircraft configuration have been measured in the NASA Ames 7- by 10-Foot Wind Tunnel. The experiment is the first in a sequence of tests designed to provide detailed data for evaluating the capability of computational fluid dynamics methods to predict the important flow parameters for powered lift. The model consists of a 60 deg cropped delta wing platform, blended fuselage and two circular in-line jets that exit perpendicularly from the flat lower surface. The measured flows have a maximum freestream Mach number of 0.2. Model angle of attack is varied between -10 and +20 deg. The flow is ambient temperature in both jet exits and the nozzle pressure ratios are varied between 1 and 3. The data presented includes forces and moments, pressures measured at 281 surface pressure ports and the pressures of the jets. Measurements of the flow are also made in the tunnel test section upstream and downstream of the model and at the jet exits to guide boundary condition selection for the planned computations. Flow visualization and total pressure measurements in the jet plumes provide a description of the three-dimensional jet efflux flowfield. Author

LOW SPEED PROPELLER SLIPSTREAM AERODYNAMIC EFFECTS

I. SAMUELSSON *In* AGARD, A Selection of Experimental Test Cases for the Validation of CFD Codes, Volume 2 21 p (SEE N95-17846 04-02) Aug. 1994

(AGARD-AR-303-VOL-2) Copyright Avail: CASI HC A03/MF A06

The data presented in this contribution to AGARD WG-14: 'EXPERIMENTAL TEST CASES FOR CFD VALIDATION' were obtained at tests in the FFA Low Speed Wind Tunnel LT1 (diameter 3.6 m) as part of an aeronautical research programme sponsored by the Swedish Board for Technical Development (STU). The intent of the experiment was two-fold: (1) to gain some physical insight to the complex aerodynamic interference phenomena occurring when the slip-stream from a highly loaded propeller washes downstream located surfaces (nacelle and wing); (2) to provide surface pressures and flow field data for evaluation of three-dimensional flow computation methods. The performed wind tunnel tests show that in high power conditions at low speeds large asymmetrical loads can develop on the nacelle and on the wing. For e.g. an aircraft with two propellers having the same sense of rotation these loads do not cancel out but combine to a net increase in asymmetrical loads (in particular side force and yawing moment). These effects, if not known or accounted for in advance, could lead to a resizing of the aircraft control surfaces and/or necessary trim changes with subsequent increased trim drag. Author

The data presented in this contribution were obtained at the Center for Rotorcraft Education and Research at the University of Maryland under part of a research program sponsored by the United States Army Research Office. The experiments were performed in several wind-tunnel entries during the period from June 1988 through June 1990. The purpose of the experiments was to provide a better understanding into the origin of rotor/airframe interactional aerodynamic effects that are present on helicopters and other rotary wing aircraft. The measured results provide several unique and challenging engineering test cases for computational fluid dynamic methods used to model helicopter rotor wakes and rotor/airframe interaction phenomena. The submission covers a series of tests on a combat aircraft research model fitted with a forward swept wing. The purpose of the tests was to investigate the flow development of the upper surface of the wing and to establish a level of confidence in the CFD methods used for the wing design. The fuselage was specified algebraically in order to permit a precise definition of the geometry both for CFD calculations and model manufacture, and the model was fitted with pressure tappings on the wing, fuselage and canard. The tests were performed in the ARA 9ft x 8ft Transonic Wind Tunnel in February 1985. Author

The submission describes a series of tests on a large half model with a constant chord, untwisted, constant section wing with 25 sweep. The aim of these tests was to investigate the influence of pylons and stores on the wing surface flow, particularly the development of shocks and separations around the pylons with an associated increase in drag. To this end a large number of surface pressure tappings were provided on the wing lower surface (17 stations), on the inboard and outboard sides of each of the pylons and around the mid-pylon store. Since these data were to be used primarily for the validation of CFD codes, for this class of configuration, the fuselage and store are precisely defined bodies of revolution which can be modelled easily by the CFD geometry packages. The tests were performed in the ARA 9ft x 8 ft Transonic Wind Tunnel in February 1986. Author

(AGARD-R-798) Copyright Avail: CASI HC A02/MF A01

The development of an analysis system for the routine calculation of gust response loads is reviewed in some detail in this report. While the system provides adequate design strength margins, a more robust and effective system would reduce user workload, computer costs and analysis time. it is suggested that other analysis systems could benefit similarly, particularly when considering the demands imposed by highly nonlinear aircraft systems, the trend toward full finite element structural dynamic models and the relentless quest for structural efficiency. It is proposed that improvements in analysis systems could evolve from the collective experience in gust loads methodologies acquired within the aeronautical community. To capitalize on that collective experience, it is recommended that a working group of gust load specialists be formed to assemble and evaluate current and promising methods for calculating gust loads and to recommend standardized airplane test cases, both rigid and elastic, for validating analysis methods and results. An experimental study was conducted to examine the flow over a non-cambered 65 deg swept delta wing with a sharp leading edge in high subsonic compressible flow at various angles of attack. This flow is known to be highly three dimensional. At certain combinations of Mach number and high angle of attack, an unsteady and often non axial symmetric phenomenon known as vortex breakdown is found to occur above the wing. The present experimental study includes both visualizations of the flow over the model surface and of the flow field itself. The surface flow visualization study is done using a conventional oil-flow visualization technique. Flow field visualizations are done using both a traditional transmission visualization system as well as a newly developed Surface Reflective Visualization (SRV) technique. The development and application of this SRV system will be the main topic addressed in the current report. The SRV technique provides a new perspective on the compressible flow over wings. This technique incorporates a specially designed model with a reflective surface to enable visualization of the flow over the wing in plan view. The technique has been developed and applied to the transonic flow over a delta wing presently under investigation in a vortex breakdown research program. The plan view perspective makes it possible to visualize the span-wise distribution of the shock system present in the flow field and provides confirmation of the existence of cross flow shocks for certain combinations of Mach number and angle of attack. Combining this technique with the use of a high-speed camera enables the high speed shock fluctuations associated with this flow to be assessed for the first time. The SRV system, thus, allows insight to be gained into the time scales associated with these shock fluctuations and the vortex breakdown phenomenon in general. Author

Two axisymmetric afterbody experimental programs, aimed at providing necessary and sufficient data for CFD code validation, were conducted in the FFA S5 suckdown wind-tunnel. Flow conditions covered the range of transonic to supersonic. Mean and fluctuating flowfield velocities in a single longitudinal plane were measured using LDA along many traverses, both over the afterbody and in the jet and mixing regions. Flow separated on the boattail of the AGARD 10 and 15 degree geometries at all conditions tested. Separation also occurred on a conical afterbody at supersonic Mach number. Comprehensive sets of boundary condition data were also recorded, through a wide variety of techniques. Extensive error analyses have been undertaken to evaluate the accuracy of all data. Transonic Navier-Stokes computations on the configurations were performed and showed the benefit of having static pressure information along the slotted tunnel roof. An algebraic stress model of turbulence returned predictions of afterbody surface pressures superior to two more simple models, in both attached and separated flow. Author

Selected results from a quantitative experimental investigation documenting the low-speed flow environment over a 75 deg swept delta wing and over a delta-canard-configuration are presented. The hot-wire measurement techniques using cross-wire and triple-wire probes are described. Results obtained include detailed flowfields of the time-dependent velocity components for angles of attack from 12.5 deg to 31.5 deg at a test Reynolds number of 1.0 x 10(exp 6). The structure of the highly turbulent vortex dominated flow is clearly shown by time-averaged, root-mean-square and spectral distributions. Thus the delta wing vortex substructure organized by discrete vortices and vortex breakdown characteristics are analyzed. With increasing incidence both the wing and the canard leading-edge vortices move inboard resulting in increase of the velocity fluctuations due to the bursting of these vortices. At the delta-canard configuration strong interference effects between the canard and the wing vortex systems are found. Peaked velocity spectra are detected in the vorticity sheets at burst flow conditions related to a narrow-band concentration of kinetic turbulent energy in the flow of the wing/canard vortex sheets. Wind tunnel evaluations of two-dimensional high-lift airfoils and of vehicles operating in ground effect near the tunnel floor require special test facilities and procedures. These are needed to avoid errors caused by proximity to the walls and interference from the wall boundary layers. Pneumatic test techniques and facilities were developed for GTRI aerodynamic research tunnels and calibrated to verify that these wall effects had been removed. The modified facilities were then employed to evaluate the aerodynamic characteristics of blown very-high-lift airfoils and of racing hydroplanes operating in ground effect at various levels above the floor. The pneumatic facilities, techniques and calibrations are discussed and typical aerodynamic data recorded both with and without the test-section blowing systems are presented. Author

A full-scale helicopter rotor test was conducted in the NASA Ames 80- by 120-Foot Wind Tunnel with a four-bladed S-76 rotor system. This wind tunnel test generated a unique and extensive data base covering a wide range of rotor shaft angles-of-attack and rotor thrust conditions from 0 to 100 knots. Three configurations were tested: (1) empty tunnel; (2) test stand body (fuselage) and support system; and (3) fuselage and support system with rotor installed. Empty tunnel wall pressure data are evaluated as a function of tunnel speed to understand the baseline characteristics. Aerodynamic interaction effects between the fuselage and the walls of the tunnel are investigated by comparing wall, ceiling, and floor pressures for various tunnel velocities and fuselage angles-of-attack. Aerodynamic interaction effects between the rotor and the walls of the tunnel are also investigated by comparing wall, ceiling, and floor pressures for various rotor shaft angles, rotor thrust conditions, and tunnel velocities. Empty tunnel wall pressure data show good repeatability and are not affected by tunnel speed. In addition, the tunnel wall pressure profiles are not affected by the presence of the fuselage apart from a pressure shift. Results do not indicate that the tunnel wall pressure profiles are affected by the presence of the rotor. Significant changes in the wall, ceiling, and floor pressure profiles occur with changing tunnel speeds for constant rotor thrust and shaft angle conditions. Significant changes were also observed when varying rotor thrust or rotor shaft angle-of-attack. Other results indicate that dynamic rotor loads and blade motion are influenced by the presence of the tunnel walls at very low tunnel velocity and, together with the wall pressure data, provide a good indication of flow breakdown. (AGARD-CP-535) Copyright Avail: CASI HC A03/MF A04

The interference effects of a three strut support system on the longitudinal aerodynamic characteristics of a model is mainly due to the guards. Our purpose is to describe two theoretical methods allowing to gain access to the level of correction to apply to the wind tunnel gross measurements. The first one is a well known panel method which provides a global correction of the forces; the second one is a simplified method which calculates separately both the displacement effect (thickness) of the guards and the mutual lift effect between them and the wing. The validity of these theoretical results has been checked by specific tests in wind tunnel F1 (ONERA) on a model of the AIRBUS A310. The experimental interference due to the struts and the influence of the model on the strut tares are also discussed. Author

A program of collaborative research between the National Research Council of Canada, Institute for Aerospace Research (IAR), and de Havilland Inc. included the design and manufacture of a slim center-line plate mount model support for installation in the IAR 1.5 m Trisonic Wind Tunnel. The primary objective of the collaborative research program was to provide a mounting method suitable for accurate measurement of the drag increments resulting from configuration changes on typical transport aircraft models. The secondary objective was to derive the tare effect of the model mounting plate so that datum aerodynamic parameters could be measured. To obtain the tare effect of the mounting plate on a model, an alternative mount from the tunnel ceiling was designed and built. The 'Y-Mount' allowed the model to be held in close proximity to a dummy plate and also to be tested without the plate in the tunnel. Comparative plate in and plate out measurements were made for a range of Mach numbers and model incidences to obtain the plate tares. Author

The structures of wind tunnel model supports always penetrate the so-called near field of the flow around the model. Therefore, support corrections of aerodynamic coefficients, evaluated either by measurement or by calculation, depend on the specific configuration of the model and of the model/support intersection. As a consequence support influences known for the correction of a wind tunnel measurement with one model are, in general, not transferrable to another configuration. Nevertheless, such a generalization, at least between models of the same aircraft family, would in principle be very helpful in avoiding the time consuming

measurements or the viscous flow calculations necessary for the evaluation of support corrections. To this end, at DNW a comprehensive data-base of measured influences of three sting support types on different low-speed aircraft models was analyzed. The aim was to split up the total support effects in terms representing the effect of support volumes located in the far field of the model and in terms representing the effect of support elements located in the near field of the model. The data-base has been analyzed with the aid of a physical model which interprets support influences as flow perturbations relevant for the wing, the fuselage, and the tail of the model. This analysis showed that for some fuselage/sting arrangements the near field effects may be considered small compared with the far field effects and independent of the wing's slat/flap configuration. These findings offered the important possibility of using near field dependent correction terms known for one model configuration for measurements with new configurations (e.g. new wing slat/flap combination). In order to determine the far field influence on new configurations, the physical model mentioned before is used in DNW's on-line data processing system to calculate the support corrections by combining previously determined flow perturbations with the actual measurements during routine tests. Examples show the successful application of the method to measurements with different models. Author

CALCULATION OF SUPPORT INTERFERENCE IN DYNAMIC WIND-TUNNEL TESTS
D. ALMOSNINO *In* AGARD, Wall Interference, Support Interference and Flow Field Measurements 6 p (SEE N95-19251 05-34) Jul. 1994
(AGARD-CP-535) Copyright Avail: CASI HC A02/MF A04

An unsteady, subsonic flow panel method is applied to predict the support interference effects in dynamic wind tunnel test simulation. Interference effects are calculated by simulating the unsteady flow around the aircraft model, both in the presence and absence of the support system, unlike common experimental techniques that try to measure these effects. The present study uses the standard dynamics model (SDM) in pitch oscillations as a test case. Calculated results for free flight conditions are compared with results obtained when simulating the presence of an existing side-wall-mounted support system in a dynamic wind-tunnel test facility. The calculated results are also compared with experimental data available from different dynamic wind tunnel test facilities. Author

An active Ground Collision Avoidance System (GCAS) was developed for the F/A-18 using the Naval Air Test Center's F/A-18 simulation. The simulation was used for the development of all three components of GCAS: (1) the algorithms used to determine the recovery initiation altitude; (2) the additional flight control laws (FCL's) necessary to perform the recovery maneuver; and (3) the visual and audio cues used to provide recovery status information to the pilot. The use of a simulation has allowed the rapid development of a viable F/A-18 GCAS that incorporates technology from the F/A-18 Integrated Fire and Flight Control (IFFC) simulation and the Advanced Fighter Technology Integration (AFTI) F-16 program. Complete system development and preliminary evaluations were performed using the simulation. This increased overall project safety while decreasing development and potential flight test costs significantly. Author

These proceedings include the Technical Evaluation Report and 58 papers of the Symposium sponsored by the AGARD Aerospace Medical Panel held at the Altin Yunus Hotel, Cesme, Turkey, April 27 - May1 , 1992. Since the commencement of aviation, accidents have occurred for a variety of reasons in both fixed- and rotary-wing aircraft. As the complexity of aviation systems increased, so did the task of investigating aircraft accidents. At the same time, advanced techniques in aviation and weapon systems have exacerbated greatly the physiological and cognitive demands on aircrews. The result is that aircraft accidents due to material causes have diminished progressively while the percentage of human factor-caused accidents has not. For individual titles, see N93-19654 through N93-19710.

An opening speech of the meeting is addressed. Two brief basic psychological effects that can cause both pilots and accident investigators to err are discussed. The first is one of the most important psychological causes of human error accidents, and is the family of effects sometimes referred to as 'hypothesis locking' or 'confirmation bias'. The second effect, or set of effects, concerns the social factors that influence crew behavior on flight decks, and the example from the database of the UK Confidential Human Factors Incident Reporting Programme (CHIRP). Today, the reality is that two-thirds of accidents and incidents are related to Human Factors. The concept of Human Factors is hard to define, identify or verify and definitions of the concept are as many as its advocates. In order to be aware of the complexity of the Human Factor in defining the root cause of an accident, to sub-categorize the concept, to be able to analyze and to see the trends over a period of time, trained experts are required. The findings, including the Human Factor findings, must influence the total report, which will form the basis of future flight safety work. I.I.C.

The term 'human factor' denotes the relationship between the aviator, the aircraft and the environment. This covers a very large and complex interrelated panorama of factors, to include as an example, personal stress, training, physiology, aircraft flight characteristics, judgement and decision making, experience, nutrition, fatigue, and motivation. A major concern in assessing the significance of any particular human factor, or combination of factors, is the method employed in the collection of the raw data

and subsequent analysis. The method of investigation and analysis employed by the U.S. Air Force, the problems inherent in this approach, and a joint, NATO human factors aircraft accident investigation methodology and program are discussed. I.I.C.

THE HUMAN FACTOR PROBLEM IN THE CANADIAN FORCES AVIATION
J. F. DAVID *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 9 p (SEE N93-19653 06-03) Sep. 1992
(AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

A 10-year analysis of human factor errors in the Canadian Air Force and where efforts should be concentrated to reduce human error are discussed. A 10-year analysis of our ground accidents and interestingly, close to 84 percent of the causes were related to personnel errors. Although the overall supervisory error was approximately 10 percent, it represented only 6 percent of the personnel error in air occurrences and close to 19 percent in ground occurrences. It was concluded that aviation psychology needs more investment. Furthermore, we cannot progress effectively in this area unless an extensive human factor data base is developed over coming decades. A human factor data base will allow for meaningful and more objective assessment by the decision makers and leaders. I.I.C.

This paper describes recent thinking about Accident Causation Theory, accident investigation and accident prevention. The central notion is that human error as the primary cause of accident causation, prevails at all levels in any complex organization and that accidents are caused by a unique network of factors, generated not only by unsafe acts of front-line operators, but also by fallible management decisions and all kinds of (psychological) preconditions that exist in the operations environment. New approaches aiming at possibilities of proactive prevention are briefly touched. Author

The investigation into the causes of accidents is an increasingly difficult undertaking because the human factors become largely prevalent in more than 75 percent of cases and everyone knows that they are delicate to interpret. Moreover the hardware is more and more comprised of electronics and software, so that the physical traces are often non-existent, outside of the parameters recorded on the 'crash recorder' and CVR. At the time of the analysis of the listings or layouts, the independent or little correlated parameters are interpreted easily, such as the driving mode and temperature. On the other hand, the quickly evolving and highly correlated parameters are harder to approach: the response of an aircraft to longitudinal and transverse stresses combined, for example. Software allowing the presentation on a graphic console of the parameters recorded from the pilot's viewpoint and animated in real time has been developed on the basis of a test by Dassault Aviation in Istres. The result satisfies all hopes: it is possible to view the flight at normal speed, at idle, accelerated, or to stop an image. The instrument panel is similar to that of the aircraft, the lever and the handle move as in reality. The horizon of the landscapes gives paravisual information of the movements of the aircraft. The investigators really 'feel' the way in which the pilot reacted to the movements of the aircraft or the events which occurred: signs of carelessness, nervousness or even a change of pilot at the controls on a two-seater. In another presentation, a model seen from the outside reproduces the movements of the aircraft for complex trend analysis: spins, stalls, etc. Finally layouts, with or without zoom, give the evolution of the desired parameters in analog, as on paper, but with more flexibility of use. A video film presenting some typical flight cases is intended to emphasize the advantages of this kind of animation. A description of the operations of data acquisition of a military aircraft is given. A flow chart of the software for presentation on a graphic console is provided. Author

A Boeing 737-400, jet transport aircraft, G-OBME, carrying 8 crew and 118 passengers, crashed near Kegworth, Leicestershire, on 8th January 1989. Of the 126 occupants, 47 died as a result of the accident and a further 74 suffered serious injury. This paper describes the structures and survivability investigations conducted into this accident by the Air Accidents Investigation Branch (AAIB) of the UK Department of Transport and reproduces the 11 AAIB Safety Recommendations (out of a total of 31 in the final report) concerning crashworthiness and survivability. This paper also describes the study performed for this investigation by the Cranfield Impact Centre, using the KRASH computer code to quantify impact pulses. The results of the KRASH work supported the AAIB recommendations in the G-OBME report and form the background to a program at the Cranfield Impact Centre to facilitate the use of impact computer codes in aircraft accident investigations. HUMAN FACTORS CAUSES AND MANAGEMENT STRATEGIES IN US AIR FORCE F-16 MISHAPS 1984-PRESENT
R. D. VANDERBEEK *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 5 p (SEE N93-19653 06-03) Sep. 1992
(AGARD-CP-532) Copyright Avail: CASI HC A01/MF A04

The F-16 was introduced into the US Air Force in 1975 as the YF-16. It began significant operational employment in the early 1980's. For this paper statistics reflect mishaps since 1984, an arbitrary starting point reflecting mature operational F-16 employment as the venerable F-4 was being phased into retirement. A review of all F-16 Class 'A' mishaps (i.e. loss of aircraft, life, or damage exceeding $1 million) from January 1984 through the end of March 1992 is presented. These mishaps are first listed within traditional causal categories. The mishaps where operator factor was cited are then recategorized into an expanded umbrella framework reflecting operationally meaningful subsets of situational awareness (SA). This SA framework more clearly demonstrates the role and importance of pilot attention and broader awareness in mishap avoidance. A program developed by Tactical Air Command, United States Air Force, to improve pilot attention and awareness is then discussed. Author

This assessment of the air accidents in the French Air Force covered the period 1977-1990. During this period, combat aircraft of the new generation were brought into service without an important variation of the number of air accidents being observed, although the rate of accidents per 10,000 hours of flight appears higher for new aircraft. The human factor remains the main cause of the air accidents in the combat category, but seems to be implied with less frequency with aircraft of the new generation. Mortality during combat accidents has tended to decrease regularly since 1987. Author

The authors reviewed the files of 114 combat and training aircraft class A mishaps in the Belgian Air Force during the period from 1970-1990 with the cooperation of the office of the 'Belgian Accident Investigation Board'. They searched for the causes of these accidents i.e. Operational related, Logistics related and environmental factors, as well as contributory factors which played a role in these mishaps. While considering the causes of these accidents, they found that 71 percent were operational related, 22 percent logistics related and 7 percent were caused by environmental factors, such as birdstrike, foreign object damage (FOD) to the engine and unknown. From the 23 training aircraft lost, only one single aircraft crash was caused by a technical failure. The overall attrition rate for the period was 1.08/10.000 Aircraft Hours (A/C) hours, being 1.43/10.000 for combat A/C and 0.55/10.000 for training A/C. The introduction of the agile F-16 fighter in the early 1980's, coinciding with a serious decrease of the annual flying time and an undermanning in terms of experienced pilots in the squadrons was most probably responsible for the negative trend in the evolution of the annual attrition rate until 1989. Although the Belgian Air Force remained two years without a major accident, it must resolutely continue its effort in the field of accident prevention. By extending the time spent by aircrews in an operational squadron, supervised by experienced pilots, the Belgian Air Force should be able to reduce class A mishaps in the future. Author

Human error has been a causal factor in 80 percent of U.S. Army aviation accidents. The focus of an accident investigation is to identify the task errors and related system inadequacies that contributed to the accident occurrence. Within the U.S. Army, crew error aviation accidents have been attributed to one of five reasons: individual failure (41 percent), leader failure (27 percent), standards failure (15 percent), training failure (12 percent), or other failure (5 percent). This study describes the most frequently occurring aircrew task errors and associated problem areas causing U.S. Army rotary wing accidents from FY-84 through FY-91. A total of 554 accidents occurred, resulting from 906 aircrew errors. The three most frequently occurring task errors involved improper decision, improper attention, and inadequate communication. Together, they accounted for one half of the total number of identified errors. The most frequently reported problem areas were inadequate crew coordination and improper scanning, which accounted for almost 40 percent of the errors. There were minor differences noted for problem areas based on aircraft type, time of occurrence, and responsible aircrew member. The U.S. Army Aviation Center has introduced corrective measures that address these problem areas. If successful, these corrective measures should reduce crew error, resulting in fewer accidents and a savings in personnel and equipment. Author

In 1982, Brooks and Rowe completed a 20 year retrospective review of the survival of all Canadian Military aircrew from ditching, parachuting or ejecting into both fresh and sea water, including the penetration of ice on frozen rivers and lakes. For the purpose of that study, all of these mishaps were classified as water accidents. The authors originally had intended to examine all water accidents back to 1952, but due to integration of the services and coincidental amalgamation of the RCAF Institute of Aviation Medicine and the Defence and Civil Institute of Environmental Medicine data prior to 1962 appeared to have been lost or destroyed. This paper summarizes the Canadian Military experience with ditching helicopters into water over the last 38 years. I.I.C.

During the years 1980-1991, 11 French Navy helicopters ditched in the sea: 3 Super-Frelon, 3 LYNX-WG13, 3 Alouette 3, and 2 Alouette 2, 10 of them being equipped with flottability devices. Structure default was the identified cause of the accident in 2 cases, engine failure in 5 accidents, human error in 5 issues, the last one being unknown. Three accidents occurred at night, the 8 others during day-time. 54 persons (34 crew, 20 passengers) have been involved. The outcome has been: 19 dead or disappeared, 4 wounded and 31 uninjured. The aircraft capsized in 8 out of 11

occurrences, almost immediately after ditching in 6 cases, after a delay long enough for all the crew to escape in 2 cases. In one of these last occurrences, all the crew but 1 survivor (13 people) died (probably from cold exposure). In the other one (ditching in shallow warm waters, close to shore) no casualty occurred (10 safe). Escape problems have been reported in 2 accidents (5 people involved), leading to 3 casualties and 1 injured. Localization of survivors has been a major problem in 1 accident (visibility was so poor that only sound signals could be efficient). Author

This paper examines the United States Navy/Marine Corps' (USN) experience with helicopter Class A over water mishaps for the period from 1977 to 1990. There were 137 helicopter Class A flight mishaps over water during this period with an overall survival rate of 83 percent in survivable water crashes. During this period, the USN developed several programs to improve survivability. The helicopter water survival training device (WSTD or 9-D-5 device) was instituted in 1982. The helicopter emergency escape device system (HEEDS) and the helicopter emergency lighting system (HEELS) were implemented in 1987. This study attempts to answer the question whether or not these programs have, in fact, improved survival since their implementation. In addition, the study reviews the types of operational problems encountered with these devices. The results indicate that the WSTD and HEEDS may have contributed to the statistically significant improved survival seen among Navy aircrew in night crashes. They may have also contributed to the improvement (not statistically significant) in survival among passengers in night crashes. The data were inconclusive with respect to the effects of HEELS because of its not being implemented throughout the fleet. Operational problems with these devices were minor and the benefits of each program far outweigh any risks. In fact, in night crashes aircrew had significantly higher likelihood of survival than passengers who were essentially untrained occupants. Other factors, in addition to the devices studied, may have also affected survival probabilities.

CRASH EXPERIENCE OF THE US ARMY BLACK HAWK HELICOPTER

DENNIS F. SHANAHAN *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 9 p (SEE N93-19653 06-03) Sep. 1992

(AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

The U.S. Army UH-60A, Black Hawk, helicopter is the first helicopter designed and built to modern crashworthiness standards. During the design of the Black Hawk, all common injury mechanisms were considered, and significant attempts were made to eliminate foreseeable injury hazards. Most important, the aircraft was designed to withstand an 11.6 m/s (38 ft/s) vertical impact without acceleration injury to the occupants or collapse of structure or high mass items into occupied space. Crew and passengers were provided energy attenuating seats and state-of-the-art restraint systems. Head strike zones were considered and potentially injurious objects excluded from these zones. Additionally, the helicopter was equipped with an advanced crash resistant fuel system. First fielded in 1979, the Black Hawk now has accumulated over 1.1 million hours of flight time. Over the 11-year period from 1 October 1979 to 30 September 1990, there have been 75 class A and B mishaps of the UH-60 resulting in 84 fatalities and 121 personnel injured. Systematic analysis of these crashes has accumulated adequate data to assess the effectiveness of the crashworthiness features of the Black Hawk. The Black Hawk has proven itself to be highly crash survivable even in impacts up to 18.3 m/s (60 ft/s) vertical velocity. Most notable have been its structural integrity, tie-down strength of seats and restraint systems, effectiveness of energy absorbing seats and landing gear, effectiveness of the crash resistant fuel system, and retention of high mass items. Mitigating against this has been a higher than predicted accident rate, a markedly increased vertical velocity at impact compared to most other helicopters in use by the U.S. Army, and a tendency for the roof to collapse in high vertical velocity crashes. Author

US ARMY HELICOPTER INERTIA REEL LOCKING FAILURES

B. JOSEPH MCENTIRE *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 6 p (SEE N93-19653 06-03) Sep. 1992

(AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

The inertia reels utilized in U.S. Army helicopters are regulated by MIL-R-8236. This is a performance specification which requires the MA-6 and MA-8 inertia reels to automatically lock when the restraint strap is subjected to an acceleration between 1.5 and 3 G. A review of U.S. Army Safety Center, Fort Rucker, Alabama, mishap data revealed a number of critical and fatal injuries attributed to upper torso flailing that occur in survivable mishaps. Some of these injuries relate directly to the inertia reel either failing to lock or not automatically locking soon enough. Laboratory sled tests have revealed sporadic failures of the inertia reel in both its auto lock and manual lock positions. Inertia reel failures during high horizontal impacts are believed to be due to high rotational velocities of the ratchet wheel which may prevent the locking pawl from properly engaging the sprocket. Inertia reel failures during high vertical impacts are believed to be caused by the low forward acceleration (G(sub x)) transmitted to the shoulder strap because of torso compression, rolling, and slumping. The lack of inertia reel maintenance and calibration procedures potentially allow the automatic lock sensitivity settings to drift to unacceptable levels over time. The influence of operational conditions (i.e., sand, dust, salt fog, temperature, humidity, etc.) on sensitivity settings are unknown. Field tests of 110 inertia reels at Fort Rucker, Alabama, airfields revealed a 24.5 percent failure to lock at the 3 G requirements. Corrective actions being considered include: (1) establishing calibration and maintenance procedures, (2) revising MIL-R-8236 to incorporate dynamic sled tests and (3) development of an inflatable body and head restraint system.

US ARMY'S AVIATION LIFE SUPPORT EQUIPMENT RETRIEVAL PROGRAM REAL WORLD DESIGN SUCCESSES FROM PROACTIVE INVESTIGATION

JOSEPH R. LICINA and ARTHUR C. SIPPO (Ohio National Guard, Columbus.) *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 7 p (SEE N93-19653 06-03) Sep. 1992

(AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

The U.S. Army Aeromedical Research Laboratory (USAARL) manages the Aviation Life Support Retrieval Program (ALSERP). The purpose of this program is to evaluate and record the efficiency of Aviation Life Support Equipment (ALSE) in the aircraft accident environment with our focus centered on rotary-wing aviation. Personal injury data are correlated with the item of ALSE provided for protection, along with information on the accident kinematics and dynamics. These ALSE items are assessed for damage to determine if the design was adequate, it was manufactured to design, and/or it was properly worn by the crewmember. These data are used by USAARL to identify design deficiencies and to substantiate the need for system improvements. The ALSE sent to USAARL for analysis includes: helmets, crashworthy seats, restraint systems, inertia reels, survival vests, and flight suites from the U.S. Army, and upon request, the Navy, Air Force, Coast Guard, and other government agencies. The primary item of equipment received by USAARL for analysis remains the helmet due to the identified criticality of head trauma in aviation mishaps.

THE EFFECTIVENESS OF AIRBAGS IN REDUCING THE SEVERITY OF HEAD INJURY FROM GUNSIGHT STRIKES IN ATTACK HELICOPTERS

NABIH M. ALEM, DENNIS F. SHANAHAN, JOHN V. BARSON, and WILLIAM H. MUZZY, III (Naval Biodynamics Lab., New Orleans, LA.) *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 9 p (SEE N93-19653 06-03) Sep. 1992 (AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

Accident investigation records at the U.S. Army Safety Center were examined to determine the frequency of gunner injuries incurred from striking the optical sighting systems in the Cobra and Apache attack helicopters during survivable mishaps. Among 105 survivable Cobra crashes during 1972-1990, the sighting system was implicated in 9 minor and 5 major injury cases, and 6 fatalities. The Apache had eight survivable mishaps since 1985, with only one gunner fatality which was attributed to the optical relay tube (ORT). In this Apache mishap and in the 11 Cobra cases where major or fatal injuries occurred, we theorized an airbag would have prevented serious injuries. To explore the role of airbags in reducing the severity of head strikes, we conducted 32 sled tests with and without airbags. In all tests without airbags, head strikes of the test manikin were sufficiently severe to cause facial fractures, but not necessarily irreversible brain damage. Airbags proved effective in reducing the severity of head strikes against sighting systems. Using mean values of several indicators of injury severity, airbags reduced head accelerations by 65 percent, head injury criteria by 77 percent, and head angular acceleration peal-to-peak swings by 76 percent in the Cobra tests. In the Apache tests, the airbags reduced those same indicators by 68, 52, and 83 percent, respectively. The study concludes that an airbag system, specifically designed for the Apache or Cobra, likely would prevent severe or fatal head and chest injuries. Author

PRE-FLIGHT RISK ASSESSMENT IN EMERGENCY MEDICAL SERVICE (EMS) HELICOPTERS

R. J. SHIVELY *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 4 p (SEE N93-19653 06-03) Sep. 1992 (AGARD-CP-532) Copyright Avail: CASI HC A01/MF A04

The Emergency Medical Service (EMS) industry has been the subject of several television and newspaper articles (Harvey and Jensen, 1987) which emphasized the negative aspects, (e.g., fatalities and high accident rates), rather than the life saving services performed. Until recently, the accident rate of the EMS industry has been five times as high as that of other civil helicopters. This high accident rate has been coupled with the dramatic rise in the number of programs. The industry has built from a single service at its inception in 1972, to over 180 in 1987 (Spray, 1987), to the point that 93 percent of the contiguous U.S. is now covered by some type of EMS service. These factors prompted the National Transportation Safety Board (NTSB) to study the accidents that occurred between May 11, 1978 and December 3, 1986 (NTSB, 1988). The NTSB report concluded that 'Sound pilot judgment is central to safe flight operations.' They further stated that '... factors unique to EMS helicopter operations--such as the influence of the mission itself, program competition, and EMS program management perspectives--can drastically influence pilot judgment during the EMS mission.' One of the most difficult decisions that a pilot must make is whether to accept or decline a mission. A pre-flight risk assessment system (SAFE) was developed at NASA-Ames Research Center for civil EMS operations to aid pilots in making this decision objectively. The ability of the SAFE system to predict mission risk profiles was tested at an EMS facility. The results of this field study demonstrated that the usefulness of SAFE was highly dependent on the type of mission flown. SAFE is now being modified so that it can 'learn' with each mission flown. For example, after flying a mission to a particular site, an EMS pilot would input information about this mission into the system, such as new buildings, wires, or approach procedures. Then, the next time a pilot flew a similar mission or one to the same area, this additional information would be taken into account in computing a risk assessment. Author

CORRELATIONS BETWEEN ENGINEERING, MEDICAL AND BEHAVIOURAL ASPECTS IN FIRE-RELATED AIRCRAFT ACCIDENTS

G. WINTERFELD *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 6 p (SEE N93-19653 06-03) Sep. 1992 (AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

An overview is given over the present situation in aircraft fire safety as it can be derived from the 73rd AGARD-PEP-Meeting devoted to this subject in 1989. It is characterized by increasing interaction between engineering and medical/behavioral aspects. A scenario for aircraft cabin fires is first developed showing that survival times both from the technical and medical point of view are of the same order of magnitude. Although fire-hardening has contributed much to increased survival times the prospects for further progress from this side diminish. Improvements are expected from improved conditions for emergency evacuations and from occupant protection systems. Modeling studies both on engineering and medical problems are increasingly applied to fire-related problems. The use of water spray systems and smoke hoods are discussed in the paper as well as studies on passenger behavior during evacuations. The combination of medical, behavioral and engineering expertise can be used to promote and optimize passenger protection in fire-related aircraft accidents. Author

TOWARDS AN INTEGRATED APPROACH TO PROACTIVE MONITORING AND ACCIDENT PREVENTION

MICHAEL H. REJMAN, COLIN J. SYMONDS (City of London Polytechnic, England), and ERIC W. SHEPHERD (City of London Polytechnic, England) *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 5 p (SEE N93-19653 06-03) Sep. 1992 (AGARD-CP-532) Copyright Avail: CASI HC A01/MF A04

Most traditional accident prevention programmes are based on information learned from accident research. While acknowledging the contribution from this approach, two difficulties can be identified. First, many accidents may be the product of a unique combination of circumstances. Second, the whole process is 'reactive'. In contrast, the research initiative reported here begins with the premise that the components of any organization may already hold much information which could be relevant to safety research and which could be used 'proactively'. A novel feature of the methodology outlines in this programme is that each of the areas can be considered as stand-alone models, capable of providing useful management information in their own right. Taken together, they represent a powerful and integrated approach to an organization's flight safety and accident prevention programme. I.I.C.

ACCIDENTS AND ERRORS: A REVIEW OF RECENT UK ARMY AIR CORPS ACCIDENTS

MICHAEL H. REJMAN and COLIN J. SYMONDS (City of London Polytechnic, England) *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 7 p (SEE N93-19653 06-03) Sep. 1992 (AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

Aircraft accidents can be categorized in a number of different ways (e.g. aircraft type, amount of damage, nature and severity of injuries sustained). Similarly, causation can be attributed to a variety of different factors (e.g. aircrew error, technical failure, operational hazard). Of all the labels used in such schemes, the one which consistently dominates the list of causes is that referred to as 'human error'. In this respect the accident statistics of the UK Army Air Corps (AAC) are no exception. However a label such as 'human error' is not particularly enlightening with regard to accident aetiology, nor does it immediately suggest obvious areas for remedial action. To satisfy these requirements, more detailed categorization schemes are necessary. Three such schemes were applied to a sample of recent AAC accidents for which human factors investigations were available. Two of the schemes had been developed within the field of aviation accident investigation while the third represented recent development within cognitive

psychology. To date, around half of the accidents held in the database have been subjected to analysis. Preliminary results suggest that while all the schemes were useful, one particular scheme was easier to implement than the other two, provided a good understanding, and indicated areas for remedial action. The exercise is being extended to cover a larger sample. Author

PREDICTION OF SUCCESS FROM TRAINING
COLIN J. SYMONDS, MICHAEL H. REJMAN (Army Personnel Research Establishment, Farnborough, England), and ERIC W. SHEPHERD *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 8 p (SEE N93-19653 06-03) Sep. 1992

Any training system contains information on the past and current performance of its students. However, such systems may also hold predictors capable of estimating the potential of a student. Failures that occur late during a course result in wasted costs, time and places, and also student career discontent. Therefore identifying the earliest indicators of failure is of primary importance to the operation of an efficient system. Research directed at uncovering these involves the identification of relevant behaviors; classification of the students' behaviors in real life situations; coding the classifications to form data points; and the application of analytic techniques to produce predictive models of behavior. The major emphasis of this paper is to describe attempts to define statistically derived criteria for success and failure in an existing flying training system. It is argued that the introduction of more objective techniques such as those described here may not only make the training system more efficient but may also reduce flight safety risks. Author

MISSION PLANNING SYSTEMS FOR TACTICAL AIRCRAFT (PRE-FLIGHT AND IN-FLIGHT) [SYSTEMES DE PLANIFICATION DES MISSIONS POUR AVIONS TACTIQUES (AVANT VOL ET EN VOL)]
Dec. 1992 62 p
(AGARD-AR-313; ISBN-92-835-0697-9) Copyright Avail: CASI HC A04/MF A01

AGARD Joint-Working Group 15 was established to review mission planning systems and to consider how they are likely to evolve in the future. Its terms of reference specified a program of two phases and the work carried out in the first of these was previously published as AGARD Advisory Report 296. This report covers the work of phase 2. The principle objective of the phase 2 studies was to investigate in detail the distributed mission planning process, dynamic prediction of battle evolution, interoperability, airborne mission planning, mission rehearsal, data filtering/fusion, data protection, communication, testing/validation, artificial intelligence, computer graphics, system architectures, and man/system design. The principle objective was also to assess how these would develop in the future and how such developments would impact upon future mission planning systems. An additional task was to recommend any research and development programs which were identified as being important to future improvements in mission planning systems. Derived from text

IN-FLIGHT AIRCRAFT STRUCTURE HEALTH MONITORING BASED ON SMART STRUCTURES TECHNOLOGY
C. BOLLER and R. DILGER *In* AGARD, Smart Structures for Aircraft and Spacecraft 19 p (SEE N94-11317 01-24) Apr. 1993
(AGARD-CP-531) Copyright Avail: CASI HC A03/MF A04

Aircraft are known to be highly complex systems requiring an extensive amount of monitoring because of their safety criticality. To reduce direct operating or life cycle cost a lot of effort was spent on automated monitoring systems. On-board loads monitoring systems for aircraft as well as built in test equipment in avionics systems are already available nowadays. On-board loads monitoring systems however do not monitor damage in-situ and on-board. This still has to be performed on-ground by manual nondestructive testing (NDT) inspection. Smart structures technology is a means which can support development towards automated in-situ monitoring of damage even on-board the aircraft. The paper starts with a brief view on aircraft maintenance cost, describes existing aircraft health and usage monitoring systems as well as NDT procedures, and explains how these procedures could be combined to a smart system using smart materials and structures technology. A strategy is proposed how gradual introduction of smart structures technology into structure health monitoring systems can make this new technology beneficial for aircraft operators in short term. STRUCTURAL HEALTH MONITORING USING EMBEDDED FIBRE OPTIC SENSORS
P. A. TUTTON and F. M. UNDERWOOD *In* AGARD, Smart Structures for Aircraft and Spacecraft 10 p (SEE N94-11317 01-24) Apr. 1993
(AGARD-CP-531) Copyright Avail: CASI HC A02/MF A04

Structural health monitoring on military aircraft is currently carried out via strain gauges attached to the surface of the aircraft structure. A parametric system based exclusively on flight parameters is being developed for use on EFA. Both of these systems monitor the airframe fatigue life. With the emergence of Smart Structures technology, a new method of structural health monitoring is feasible that has perceived advantages over the current technology. How fiber optics embedded within a composite laminate can be used to monitor strains within the aircraft structure, and hence its fatigue life is described. Embedded fiber optics can be used to monitor sustained damage - battle or low velocity impact damage, give a full flight history and, with diagnostic capability, unconditioned maintenance would be available. A bibliography of publications held by NASA on aspects of aircraft flight safety is provided. The abstracts are listed by the following topics: human errors, injury reduction, engines, structures and materials, aircraft aging, fire, adverse weather, aircraft maintenance, future safety requirements, and miscellaneous items. The bibliography was compiled originally as a contribution to a conference on aircraft flight safety, sponsored jointly by AGARD and the Russian International Integration Association, which was held in Russia in August/September 1993. Modern helicopters usually incorporate many engineering systems (including pilot-aiding systems such as autostabilizers and flight directors) which are essential to the safe and effective use of the helicopter. Where the helicopter can be endangered by failure of a system (or of one of its units), that system is termed flight-safety-critical. In general, the use of those systems should not incur a higher probability of hazard to the helicopter than that considered acceptable from considerations of structural or mechanical failure. In assessing the suitability of a helicopter for its intended mission(s), it has become increasingly important to consider the effects of the various systems provided. In particular, assessments of the implications of systems performance and failures derived from calculation and ground test should be validated by flight tests. This paper seeks to establish the general principles applicable to the testing in flight of any flight-safety-critical system, with emphasis on certification rather than system development. It does not deal with the testing of particular systems, but it is

hoped that readers will find the principles described readily applicable to specific cases. This document has been sponsored by the Flight Mechanics Panel of AGARD. Author (revised)

FLIGHT IN AN ADVERSE ENVIRONMENT [LE VOL EN ENVIRONNEMENT HOSTILE]

Nov. 1994 161 p Lecture series held in Brunswick, Germany, 7-8 Nov. 1994, in Lisbon, Portugal, 10-11 Nov. 1994, and in Atlantic City, NJ, 15-16 Nov. 1994

(AGARD-LS-197; ISBN-92-836-1006-7) Copyright Avail: CASI HC A08/MF A02

The environment in which an airplane must operate is a major cause of aircraft accidents. This lecture series focuses on specific aspects of the environment, both natural and man-made, which are the major contributors to these accidents as follows: (1) wake turbulence and the generation of trailing vortex systems; (2) the results of an extensive flight test program concerning winter storms off the east coast of Canada including effect on aircraft operations; (3) electromagnetic effects including electrical discharge properties, in-flight test program, in-flight lightning models and lightning simulation techniques; (4) response of an aircraft to wind shear and methods of detection and quantifying this natural hazard; (5) heavy rain effects on aircraft systems performances in the light of full scale and model tests; (6) measurements of atmospheric turbulence, treatment of aircraft response to random turbulence and discrete gusts. For individual titles, see N95-14894 through N95-14900.

ESD AND LIGHTNING INTERACTIONS ON AIRCRAFT

JEAN LOUIS BOULAY *In* AGARD, Flight in an Adverse Environment 19 p (SEE N95-14893 03-03) Nov. 1994

(AGARD-LS-197) Copyright Avail: CASI HC A03/MF A02

Under certain adverse conditions, particularly inside or in the vicinity of clouds, aircraft may be affected by two different electric phenomena: electrostatic discharges and lightning discharges. When electrostatic charges accumulate on an aircraft structure, electric discharges occur. These discharges generate RF interference that severely impairs the operation of onboard radio navigation and communication equipment. Sometimes energetic discharges have direct effects on structural components like radomes, windshields and canopies. Lightning discharges may have a very powerful and dangerous effects on an aircraft in flight. The electromagnetic coupling of any repetitive current pulses through the airframe can upset or deteriorate airborne equipment; and under certain circumstances, lightning flashes may also cause serious direct damage to structural components. ICING: ACCRETION, DETECTION, PROTECTION

JOHN J. REINMANN *In* AGARD, Flight in an Adverse Environment 27 p (SEE N95-14893 03-03) Nov. 1994

(AGARD-LS-197) Copyright Avail: CASI HC A03/MF A02

The global aircraft industry and its regulatory agencies are currently involved in three major icing efforts: ground icing; advanced technologies for in-flight icing; and tailplane icing. These three major icing topics correspondingly support the three major segments of any aircraft flight profile: takeoff; cruise and hold; and approach and land. This lecture addressess these three topics in the same sequence as they appear in flight, starting with ground deicing, followed by advanced technologies for in-flight ice protection, and ending with tailplane icing. WIND SHEAR AND ITS EFFECTS ON AIRCRAFT

ALAN A. WOODFIELD *In* AGARD, Flight in an Adverse Environment 31 p (SEE N95-14893 03-03) Nov. 1994

(AGARD-LS-197) Copyright Avail: CASI HC A03/MF A02

Wind shear has been responsible for several major accidents and many incidents during landing and take off. In aviation terms, wind changes that cause flight path deviations (wind shear) are mainly those occurring over distances between about 150 and 3000m, i.e. approximately 3 to 40 sec. at approach speeds. General characteristics of many forms of wind shear are described together with measured data on the probability of meeting headwind shears of different magnitudes. This is followed by analysis of the basic response of aircraft to both horizontal wind changes and downdrafts, and discussion of aircraft sensitivity to wind shear. Several recorded examples of wind shear in both normal operational and accident scenarios are presented. The relevance of different ways of quantifying wind shear severity is examined, including a calculation of height loss that can be used when a wind shear is fully defined, and the 'F' factor, which is used with reactive wind shear measuring systems. Some insight into the probabilities of false or missed warnings with each system is derived using the measured probability data. A brief outline is given of the relevant characteristics of different wind shear prediction and detection systems. The lecture concludes with a study of the ways in which pilots can be trained and assisted to survive most wind shear encounters and, hopefully, avoid those which could be catastrophic. It is concluded that, given appropriate training and aircraft systems, it is possible to survive encounters with nearly all those wind shears that caused fatal accidents in previous years. New predictive detection systems offer the possibility to warn an aircraft before it attempts to penetrate those extremely rare wind shears that are beyond its performance capability. Author

HEAVY RAIN EFFECTS

R. EARL DUNHAM, JR. *In* AGARD, Flight in an Adverse Environment 17 p (SEE N95-14893 03-03) Nov. 1994

(AGARD-LS-197) Copyright Avail: CASI HC A03/MF A02

This paper summarizes the current state of knowledge of the effect of heavy rain on airplane performance. Although the effects of heavy rain on airplane systems and engines are generally known, only recently has the potential aerodynamic effect of heavy rain been recognized. In 1977 the United States Federal Aviation Administration (FAA) conducted a study of 25 aircraft accidents and incidents which occurred between 1964 and 1976 in which low-altitude wind shear could have been a contributing factor. Of the 25 cases (23 approach or landing and 2 take-off) in the study, ten cases had occurred in a rain environment, and in five cases these were classified as intense or heavy rain encounters. These results led to the reconsideration of high-intensity, short-duration rainfall as a potential weather-related aircraft safety hazard, particularly in the take-off and/or approach phases of flight. Impulsive forces applied to an aircraft fuselage generate radial vibration waves in the structure analogous to those in a classical thin shell. It has been found that these waves are detected by the cockpit area microphone, and that spectrogram analysis of the microphone recording can provide information on the nature, origin and strength of the source, whether an explosion or a sudden decompression. Rotorcraft operating in high-threat environments fly close to the earth's surface to utilize surrounding terrain, vegetation, or man-made objects to minimize the risk of being detected by an enemy. The piloting of the rotorcraft is at best a very demanding task and the pilots need help from on-board automation tools in order to devote more time to mission-related activities. The Automated Nap-of-the-Earth (NOE) Flight Program is a cooperative NASA/Army program aimed at the development of technologies for enhancing piloted low-altitude/NOE flight path management and control through computer and sensor aiding. The long-term objective is to work towards achieving automation for aiding the pilot in NOE flight with a flight demonstration of resulting computer/sensor aiding concepts at an established course. The technology for pilot-centered NOE automation is not currently available. Success in automating NOE functions will depend on major breakthroughs in real-time flight path planning algorithms, effective methods for the pilot to interface to the automatic modes, understanding of visual images, sensor data processing/fusion, and sensor development. Our approach to developing the technologies required to solve this problem consist of the following phases: (1) algorithm development, (2) laboratory evaluation, (3) piloted ground simulation, and (4) evaluation in flight. An overview of the research in this area at NASA Ames Research Center is given. Author

(AGARD-CP-504) Copyright Avail: CASI HC A02/MF A03

A knowledge based computer aid for flight planning tasks as part of a Cockpit Assistant for IFR (Instrument Flight Rules) operation is presented in detail after a brief overview of the modular structure of the Cockpit Assistant has been given. Based upon the requirements of air traffic management, the system is aimed at supporting the pilot in complex planning and decision situations. By assessing the situation, flight goal conflicts are detected and avoided by offering sensible flight plan modifications to the pilot. The main features of the situation assessment and planning module are discussed with regard to knowledge representation and applied solution model. Thus, conflict detection, selection of an alternate destination and rerouting algorithms are described in detail. The present state of implementation, as tested in a flight simulation facility at the University of the German Armed Forces in Munich, is presented as well as some results of the test phase with professional pilots. The possibilities of integrating the system into the avionics of modern aircraft are discussed and an outlook is given of expanding it towards 4-D and RNAV capability and/or optimal 3-D aircraft trajectory planning under constraints from terrain, traffic and weather. COMPARISON OF THE EVENT-STEP ALGORITHM TO OTHER PATH PLANNING METHODS TO AVOID DYNAMIC 3D OBSTACLES
MARK SILBERT *In* AGARD, Air Vehicle Mission Control and Management 9 p (SEE N92-27887 18-01) Mar. 1992 Revised
(AGARD-CP-504) Copyright Avail: CASI HC A02/MF A03

In a previous paper, the Event-Step Algorithm (ESA) was presented as an efficient path planning algorithm to avoid dynamic obstacles. Dynamic obstacles are defined as obstacles that move and/or distort over time. Here, the focus is more closely on the algorithm; it is compared with other path planning algorithms. Specifically, Grid Search, Voronoi Graph and Visibility Graph methods are considered. It is shown that the ESA offers advantages over these methods and is a generalization and improvement of the Visibility Graph method. A summary of the ESA is presented. Author

The evolution of present day Air Traffic Management (ATM) towards an integrated Air Traffic Management will lead to the introduction of computer based planning systems on the ground side, which communicate with advanced Flight Management Systems onboard the aircraft via automatic data link. An experimental Flight Management System (EFMS) is under development in the frame of the PHARE program for research into future ATM concepts. This EFMS will have the capability to predict a 4-dimensional trajectory according to a set of constraints given by an ATC planning computer on the ground. It will negotiate this trajectory with ATC via data link and will generate appropriate guidance commands for the autopilot/autothrottle system to steer the aircraft along this trajectory. The functionality of the EFMS is described as well as the planning strategy for the generation of a trajectory from the departure to the destination airport which meets the defined constraint attributes. TRAJECTORY OPTIMIZATION FOR HYPERSONIC AIRCRAFT GUIDANCE
R. L. SCHULTZ, M. J. HOFFMAN, A. M. CASE, and S. I. SHEIKH *In* AGARD, Air Vehicle Mission Control and Management 16 p (SEE N92-27887 18-01) Mar. 1992 Sponsored by AFWAL
(AGARD-CP-504) Copyright Avail: CASI HC A03/MF A03

A computationally efficient, real-time trajectory optimization and guidance approach for hypersonic aircraft is described. The optimization approach is based on Euler-Lagrange energy state approximations. A three-dimensional, spherical-earth, aircraft-motion model with constraints on temperature, dynamic pressure, acceleration, and angle of attack is employed. Climb-to-orbit, return-from-orbit, flight-to-designated-landing-site, unpowered-abort, and powered-abort flight conditions are considered. Different performance criterion are used for different problems. Solution methods of varying computational complexity and performance capability are developed. An exact solution to the optimization problem using iteration on adjoint variables is developed. This method is the most exact but is not suitable for on-board processing. However, it serves as the basis of performance comparison for the approximate methods. Approximate solution methods suitable for onboard guidance are developed for the climb-to-orbit problem and the flight-to-a-landing site problem. A computationally efficient method for generating footprints is described. Footprints are used to determine when to start final descent and to identify candidate landing sites under an air-breathing-engine or rocket-engine abort or other emergency conditions. A hypersonic-vehicle guidance, navigation, and control configuration of the complete optimal guidance scheme is described. Sensitivity analysis results are included for climb-to-orbit trajectories. The probability of achieving orbit using the optimal guidance scheme and a stored nominal approach are compared. Author

SEARCH ROUTE PLANNING
J. R. VANZANDT *In* AGARD, Air Vehicle Mission Control and Management 14 p (SEE N92-27887 18-01) Mar. 1992
(AGARD-CP-504) Copyright Avail: CASI HC A03/MF A03

Planning an airborne search for a relocatable target involves minimizing the risk to the crew while maximizing the estimated likelihood of finding targets. When the number of potential sites is small, the problem reduces to finding the best (usually the shortest) route connecting them. The aircraft need not overfly each site, but must only come within sensor range of it. Thus, the search route planning problem can be modeled as a covering salesman problem (CSP) -- a generalization of the traveling salesman problem in which the tour need not visit every city, but every city must be within a certain distance of some city on the tour. The spacefilling curve heuristic for the traveling salesman problem is demonstrated, then a new heuristic for the covering salesman problem is presented and applied to the search route planning problem. When the number of sites is large, the planner must also decide which subset of them can be visited. A genetic algorithm has been developed for selecting both a set of sites to visit and an appropriate routing pattern. The procedure also accounts for the finite turning radius of the aircraft. AN EFFICIENT METHOD FOR THREE-DIMENSIONAL ROUTE PLANNING WITH DIFFERENT STRATEGIES AND CONSTRAINTS
U. LEUTHAEUSSER and F. RAUPP *In* AGARD, Air Vehicle Mission Control and Management 5 p (SEE N92-27887 18-01) Mar. 1992
(AGARD-CP-504) Copyright Avail: CASI HC A01/MF A03

A method for planning paths through a digital map is presented. The task consists of planning 3-dimensional paths for autonomous air vehicles over a terrain represented by a digital map with different strategies and constraints. Possible strategies minimize time, danger, or fuel consumption. Constraints are lateral, and vertical maximum accelerations as well as time and fuel constraints. The path planning problem can be viewed as a shortest path problem (geodesic problem) in a space with a non-Euclidean metric depending on the applied strategy. One has to minimize a cost functional giving rise to the Hamilton-Jacobi equation which is solved by Dynamic Programming techniques. Because of the digitization bias, a second optimization step consisting of direct optimization methods is sometimes necessary. The result is a fast, non-heuristic and flexible technique for strategic route planning. Author

The requirements of piloting and of day as well as night navigation of a combat aircraft force the man-machine interface into permanent evolution. The last fifteen years brought the spread of 'head high' collimators on combat aircraft. However, in spite of holographic techniques which make it possible to increase the size of the optical field presented, research relating to the improvement of the weapons system has been replaced by the creation of a new interface called 'Helmet Sight' placed in front of the eye of the pilot. This interface enables the pilot to point the sensors of the weapons system in a given direction, and, conversely to show an objective to the navigation and armament system. The size of the optical fields proposed for helmet sights, equivalent to the field of a conventional high head sight, remains insufficient to authorize piloting or navigation in full safety. At most, some parameters can be presented to help the pilot in the realization of his mission. With improving techniques, the existence of this type of interface made it possible to present a more complex image in front of the eyes of the pilot. This is called 'Helmet Sight'. A discussion of the requirements of piloting and navigation in all conditions will highlight the essential criteria taken into account for the design of these new sights. Author

The combination of Global Navigation Satellite Systems and inertial sensors can achieve extremely high accuracies in position, speed, turn rate, attitude, and acceleration of a flight vehicle. This paper presents the application of AeroNav to flight testing. AeroNav is an Integrated Navigation system, which has been co-developed between Aerodata and the Institute of Flight Guidance of the Technische Universitat Braunschweig. Due to its tight coupling between satellite and inertial sensors it can be used as the basic system for flight performance measurements and handling quality testing. Furthermore it has the potential to meet the accuracy requirements as position reference for autoland certification and ILS/MLS flight calibration. Flight and ground test results are shown, which use an independent position reference for accuracy validation. Author

Flight test results and analysis techniques are presented for an automatic All Terrain Ground Collision Avoidance System (AT GCAS). The AT GCAS was flight demonstrated on the Advanced Fighter Technology Integration (AFTI)/F-16 and hosted on a production digital F-16 flight control system. Over 200 automatic recoveries were initiated at dive angles up to 50 degrees, all bank angles, and airspeeds ranging from 270 to 570 knots. New methods were developed to analyze data, allowing identification

of subsystem error contributions. The resulting system performance is presented with conclusions. Author

Advanced guidance, control and navigation systems are becoming more functional and integrated. This paper describes Canadian experience in the development and applications of Integrated and Multi-function Navigation Systems. The emphasis is on the development of two distinct mission-specific inertially based integrated navigation systems. In particular, in a high risk development project such as the Synthetic Aperture Radar Motion Compensation System, the special attention given to the detailed assessment of key error sources and a well-planned sequence of simulation, development and flight test evaluation are essential to the success of the project. For Multifunctional inertially-based systems, the hardware design emphasis should be on IMU architectures that minimize both the acquisition and life-cycle cost, while the software design emphasis should be on practical and efficient FDIR schemes. Some comments were also offered on the trends of GPS related future applications. Author

Several recent technological developments (including the advent of GPS and the virtual explosion of computational capability) offer unprecedented opportunities for radically different approaches to providing weapon system capabilities. In the past high-rate raw sensor data would have to be sampled, or significantly pre-processed in a separate (dedicated) computer, before such data could be used within the constraints of a real time weapon system application. During such sampling/pre-processing much of the information content could be lost. The current computational capability explosion now permits highly complex algorithmic solutions to be executed within real time. Such computational capabilities within an integrated avionics architecture offer opportunities for maximum rate fusion of all raw signals directly from the sensors, where they are generated, with little or no information loss. As an example, when unfiltered GPS information is directly/optimally combined at maximum rate with inertial data, not only is the navigation accuracy increased, but effective susceptibility to GPS signal dropout/jamming is significantly reduced. Additionally, the resultant highly precise GPS/INS position, velocity, attitude, and time information can serve as a common integrating agent for combining the information from a variety of other mission sensors and communication devices. A system engineering process is required to systematically explore and exploit the yet untapped opportunities presented by these technological advancements. The essential ingredients of this process are a system level perspective, sound modeling and simulation, and the application of analytic tools. Author

ULISS NG is an Inertia-GPS unit and an interesting example of INS/GPS synergy and performance/cost trade-off. It belongs to the ULISS family of INS already fitted to a number of different aircraft. Its miniaturized code twelve channel embedded receiver, with its RF and digital modules, totals 0.7, 1, 7 kg and 12 W. Its parallel tracking maximizes navigation continuity, smoothness, accuracy and minimizes reaction time and oscillator size. The tight Inertia-GPS coupling, i.e., tight inertial aiding and tight hybrid navigation Kalman filter, has been designed to favor operational capabilities, performance and solution stability. Four versions of the SAGEM embedded GPS receiver have been developed C/A-SPS, C/A-SA-PPS and P(Y)L1 and P(Y)L1/L2. The P code version is presented in the paper. Flight tests are being conducted in a Mirage 3 at the French Official Flight Test Center of Bretigny starting in May. Author

As GPS signal availability reaches operationally useful levels, and in particular following experience of its usefulness in the Gulf operations, widespread requirements are beginning to arise for the incorporation of GPS into existing combat aircraft. A considerable amount of study and development work has been carried out by GEC Ferranti to investigate different approaches to integrating GPS into existing navigation systems with the minimum impact on installation, interfacing and operating procedures. This paper describes some different approaches to integrating GPS together with their relative merits and deficiencies. Two practical systems are described in detail and some simulation and trials results are presented together with some aspects of the GPS integration which will form the basis of future development work. Combined Satellite and Inertial Navigation Systems can achieve extremely high positioning accuracies in the sub meter range even in the dynamic environment of aircraft. This paper presents the concept of the 'Integrated Navigation System' developed at the Institute of Flight Guidance using coupled satellite and inertial sensors. Flight test results are shown, which demonstrate that this system has the potential to achieve the accuracy requirements according to ICAO CAT 3 for high precision approaches even under bad weather conditions. Algorithms are described for integration of Differential Global Positioning System (DGPS) data with Inertial Navigation System (INS) data to provide an integrated DGPS/INS navigation system. The objective is to establish the benefits that can be achieved through various levels of integration of DGPS with INS for precision navigation. An eight state Kalman filter integration was implemented in real-time on a twin turbo-prop transport aircraft to evaluate system performance during terminal approach and landing operations. A fully integrated DGPS/INS system is also presented which models accelerometer and rate-gyro measurement errors plus position, velocity, and attitude errors. The fully integrated system was implemented off-line using range-domain (seventeen-state) and position domain (fifteen-state) Kalman filters. Both filter integration approaches were evaluated using data collected during the flight test. Flight-test data consisted of measurements from a 5 channel Precision Code GPS receiver, a strap-down Inertial Navigation Unit (INU), and GPS satellite differential range corrections from a ground reference station. The aircraft was laser tracked to determine its true position. Results indicate that there is no significant improvement in positioning accuracy with the higher levels of DGPS/INS integration. All three systems provided high-frequency (e.g., 20 Hz) estimates of position and velocity. The fully integrated system provided estimates of inertial sensor errors which may be used to improve INS navigation accuracy should GPS become unavailable, and improved estimates of acceleration, attitude, and body rates which can be used for guidance and control. Precision Code DGPS/INS positioning accuracy (root-mean-square) was 1.0 m cross-track and 3.0 m vertical. (This AGARDograph was sponsored by the Guidance and Control Panel.) Author

A visual sensor data processing method has been developed and validated which allows to achieve on board autonomous landing approaches in the visual flight regime with computing technology available today; sensors are a video-camera, inertial gyros and an air velocity meter. The key feature of the method is the reconstruction and servo-maintained adjustment by prediction error feedback of an internal spatio-temporal model about the process to be controlled (4D approach). This encompasses both the ego motion state of the aircraft carrying the sensors and the relevant geometric properties of the runway and its spatial environment. The efficiency of the approach is proved both in a hardware-in-the-loop simulation and in real test-flights with a twinturbo-prop aircraft Do 128 of Dornier. For accuracy evaluation of the data gathered, the results of differential GPS and radio metric altitude measurements have been recorded simultaneously. Author

Inertial and image-derived measurements for runway referenced flight path computations are investigated. They open the way for flight-tests without ground-based sensors and with a minimum of a priori knowledge or none at all about the runway position and direction in absolute coordinates. They are ideally suited for inspecting landing aids at congested civil airports, for instance. The investigations concentrate on the problems of the baroinertial and inertial altitude measurements, on the achievable accuracies of image-derived measurements and their integration with inertial measurements. It is shown that glide path and flight track accuracies in the order of 0.01 deg (1 sigma) should be achievable. Author

A Dual Inertial Integrated Navigation System (DIINS) is being developed for the Canadian Navy to improve the navigational accuracy and reliability on ships which have two inertial navigators plus other aiding navigation systems and sensors such as GPS, Loran-C, Omega, Doppler Speed Log(s) and so on. The sensor integration architecture being proposed to optimally combine all navigation sensors on such a vessel is an 'hierarchic alliance' of Kalman filters, which is designed to allow sensitive error compensation as well as complete fault detection isolation and reconfiguration (FDIR). This architecture is ideally suited to central processing, can take advantage of parallel processing, and provides significant advantages over both the conventional unifilter approach and the 'federated' (or cascaded) filter approach. This hierarchic alliance consists of a specific set of optimal filters running in parallel, with each filter processing measurements from a different subset of the navigation sensors. These filters can be partially ordered so that primary and secondary filters can be defined. The primary filter(s) provide the optimal navigation solution, while the secondary filters provide uncorrupted backup in the event of a sensor fault. The primary motivating factor for this architecture is to provide optimal integration under all conditions, and in particular after the occurrence of subtle sensor faults which could not be immediately detected and which could therefore corrupt the primary filter(s). This alliance of filters can provide an uncorrupted optimal solution, since it can be configured so that there will always be a secondary filter which, at the time of failure, was running independently of the faulty sensor. This removes the usual need to 'back out' of a failure which was not immediately detected and thus substantially simplifies reconfiguration in response to such a failure. Another motivating factor for this architecture is that the partial independence of the parallel filters also facilitates the detection and isolation of sensor faults. This can be accomplished by multiple levels of statistical hypothesis testing on a set of parallel Kalman filters. Fault detection techniques used include the usual sensor data reasonableness and filter residual tests as well as a chi-square hypothesis testing technique applied to the state vectors, and inter-filter voting applied to the residuals test results. While this approach is computationally intensive, modern software techniques, and soon to be available processing power, are expected to make the real time implementation of this hierarchic alliance of filters quite practical. The system envisioned in this paper is being designed and built at the Defence Research Establishment Ottawa for the Canadian Navy and is expected to see initial real-time sea trials in 1993. Author

The Air Force Avionics Laboratory has sponsored several efforts to increase the accuracy of aircraft navigation functions while decreasing crew workload through the application of intelligent systems. Two such efforts were the Adaptive Tactical Navigation (ATN) System and the Autonomous Fixtaking Management (AFM) system, which were both awarded to The Analytic Sciences Corporation (TASC). An intelligent system to aid the pilot with navigation functions was developed under the ATN program. This system incorporated real-time knowledge base software to manage the tactical navigation moding, fault tolerance, and pilot aiding to provide a robust navigation prototype for the next generation fighter aircraft. The ATN program highlighted the aircraft weapons officer's heavy workload associated with the location and identification of fixpoints to update and verify the accuracy of the navigation system. With this problem in mind, it was determined that an intelligent system was needed to automatically locate, image, and identify fixpoints and update the navigation solution. The AFM System was developed to prove the feasibility of automated navigation updates using tactical sensors and existing mission data processing systems. Several technologies developed under ATN were incorporated into the AFM system including a proven simulation of the navigation sensors, controllers, and mission planning and management software. Automation of human fix taking activity required integration of several emerging technologies including a real-time data fusion architecture, neural network and heuristic automatic recognition algorithms, and associative memories to retrieve fix points from on-board databases. Integration of these diverse technologies was simplified by the employment of an object-oriented software development approach and real-time control system. Derived from text

Visual presentation is a major source of information for air traffic control. Significant advances in computers, display technology, and the tools used by developers of intelligent air traffic management (ATM) systems pose challenges for the development of computer-human interfaces (CHI's) associated with the new automation. The CHI must be designed to be both usable and suitable. This paper reviews three capabilities available to developers of intelligent ATM systems: case-based reasoning system design, rule-based system design, and individually tailored CHI. It recommends that any intelligent ATM system be examined early in its development cycle in a laboratory environment, where it can be tested in concert with other elements of the ATM system. Author

Complete automation of an air traffic control system requires the identification of functions and their allocation to a distributed system, part of which is on the ground and part of which flies. The evolution of current systems appears to be taking place with ill-defined visions of what the final system will or should look like. In some cases this fuzzy view of the future is purposely carried because of the implications of proposing a view which antagonizes various groups or associations representing those already engaged in the process. Yet, each step along the way implies explicitly or implicitly some final target system. As each year goes by, we move toward a system which may be a long way from what is really desirable in the next century. It seems reasonable that some versions of the ideal future system should be understood within the community. At least one of these options should be what is technically feasible. From this, an acceptable system can be negotiated. The first step in this process is to determine the desired functionality without regard to any other factors. From this, technical feasibility can be determined and/or predicted; and finally, the allocation of the functions to humans or machines can be debated. The management of a dense cluttered air space requires a set of skills and capabilities on the part of an air traffic control team which, in some of their functions, cannot be represented algorithmically. Successful automated air traffic management systems will necessarily emulate the intuitive portions of the human management capability using various technologies drawn from the broad field of artificial intelligence. Indeed portions of the overall management system have been the subject of research and development efforts in many laboratories around the world. The integration of these fragments into an overall scheme is often left as an implicitly understood architecture. This paper begins by presenting CompEngServ (CES) Ltd.'s view of an automated airspace management system. The paper then presents an overview of the prototype of an advanced controller workstation developed by CES (under contract to Transport Canada) which prototypes various portions of this architecture for Airspace Management. This system represents the state of the art in Air Traffic Control (ATC) research. This prototype is also an example of multiple hardware and software technologies being harnessed to develop a solution to a problem initially thought to be too complex for automation. The paper then presents the future direction of research at CES and then closes with the issues which have been raised by our work that need addressing before an automated system will be practical. The CENA is in charge of studies related to Air Traffic Management and therefore to some of the communication, navigation, and surveillance means. The work is carried out to support French and European ATC (air traffic control) in an international cooperation. It encompasses studies and experimental development aiming at operational implementation within the CAUTRA 5 program. The different CENA projects are integrated in an experimental simulator frame named ADER. This test-bed

will support one of the demonstrations within PHARE, a joint European experimental program. The CENA organization is based upon a technical directorate in charge of the horizontal projects as previously described and 10 divisions located either at Athis-Mons (near Paris) or in Toulouse. One of these divisions, called COA (Control Organization and Automation), deals mainly with studies aiming at providing ATM (air traffic management) operators with helpful decision tools, using advanced methods and technologies. In this paper, it can be found a short description of COA division activities and a more precise analysis of one of the projects, called GOETHE, aiming to provide ATFM (Air Traffic Flow Management) regulators with a more user-friendly tool.

The major challenge facing the world's aircraft/airspace system (AAS) today is the need to provide increased capacity, whilst reducing delays, increasing the efficiency of flight operations, and improving safety. Technologies are emerging that should improve the performance of the system, but which could also introduce uncertainty, disputes, and inefficiency if not properly implemented. The aim of our research is to apply techniques from intelligent control theory and decision-making theory to define an Intelligent Aircraft/Airspace System (IAAS) for the year 2025. The IAAS would make effective use of the technical capabilities of all parts of the system to meet the demand for increased capacity with improved performance. Author

The Global Positioning System NAVSTAR is rapidly becoming the world standard for navigation and timing. Although primarily designed to be a military system, the civil user community is expanding at a breathtaking pace. After an introduction to the general GPS policies and the technical fundamentals this paper presents an idea on how to use GPS NAVSTAR to improve Air Traffic Control. Existing selective identification features will form the key to a GPS-based position, velocity, and acceleration message. Higher update rates and the vastly improved information on each aircraft will provide the input for a flight plan correlation function enabling an automatic air traffic monitoring and control far beyond current standards. Air traffic in Central Europe is dramatically increasing today. There are some indications that present upgrades of the air traffic control system might not be efficient and that planned upgrades will not be realized in time due to budgetary restrictions. One key element in air traffic control is a precise navigation of the aircraft during landing, the most critical part of the flight. It is presently performed by use of the instrument landing system ILS and in some areas already by the microwave landing system MLS. The latter provides a very high navigation performance and allows a high landing sequence under all weather conditions. However, it requires extensive ground equipment at the airports and hence, only a few airports in Central Europe are equipped with it today. This paper presents the results of a study on a new microwave landing system with a spaceborne radar transmitter and airborne radar receivers. Based on this bistatic radar system, navigation in landing phase could also be performed independently from weather conditions. However, it does not require any active equipment at the landing site. Even taxi way guidance could be performed with this system. It is called 'Ground Independent Landing System' (GILS). Author

The actual implemented Air Traffic Control (ATC) systems have radar coverage gaps on the Northern Atlantic and Trans-Siberian Routes as well as in the Pacific area. This situation results in insufficient air traffic surveillance information in the corresponding control sectors and larger separation between aircraft on these routes to ensure safe operation. Unfortunately, this procedure reduces the capacity and limits air traffic flow. These problems can be overcome by the worldwide use of the high accurate position data from Global Navigation Satellite Systems (GNSS) such as the U.S. Global Positioning System (GPS) and the Russian Global Navigation System (GLONASS) aboard the aircraft as proposed by the ICAO-FANS plan. In combination with the Automatic Dependent Surveillance (ADS) function as specified by ARINC 745, the onboard computed position and flight path data is transmitted to the Aeronautical Telecommunication Network (ATN) for further use by ATM and ATC. Based on these principles, Deutsche Aerospace AG, Airborne Systems Division has developed a demonstrator. This system integrates the precise (Differential) GNSS information with the data from an Inertial Measurement Unit (e.g. AHRS) aboard the demonstrator aircraft to fulfill the accuracy and consistency/integrity requirements during all phases of flight. This system integration has been done to ensure integrity of GNSS position information during satellite outages or satellite masking, e.g. during turns. For demonstrating ADS-functionality, the onboard computed position and flight path velocity is transmitted in combination with flight management information to the ground system using a data link. In addition to this en-route ADS function with medium accuracy requirements, a high accuracy mode using Differential GNSS data for conflict detection calculations between low separated aircraft has been implemented. The conflict detection and alert functions are based on a special designed Expert System capable of real time operation. A taxi monitoring function can also be performed by the system. All system functions have been tested and demonstrated during flight trials using a VHF data link for communication. Results of these flight tests will be presented. Author (revised)

Enhancement of air traffic capacity within the TMA cannot be achieved easily. Single solutions and improvements of technical equipment, procedures and standards, with automation support for human operators in isolated areas, e.g. for the management of the airport, airspace and Air Traffic Control very often will only yield marginal capacity increases. Whether it is: new concrete (runways, taxiways, aprons), reduced separation minima, or advanced ATM functions, all these measures will only result in significant capacity increases, if they are designed, developed and implemented in a comprehensive, combined effort, making use of set of complementary measures and functions in a well structured, optimized architecture and implementation strategy. This comprehensive approach is especially true for high density TMA's/airports, operating close to capacity limits, where any capacity enhancement measure will directly affect and/or require capacity related issues in other areas. Based upon the specific needs of the Frankfurt airport and TMA, DLR is working on a variety of tools and functions, which--combined and implemented in a well designed strategy plan--can yield significant capacity increases without the construction of new runways. Three candidate

systems--under development or even already in operation--which mutually depend on and complement one another will be presented as examples of an even larger capacity enhancement plan for the TMA. Derived from text

A system for the automated management and control of terminal area traffic, referred to as the Center-TRACON Automation System (CTAS), is being developed at NASA Ames Research Center. In a cooperative program, NASA and FAA have efforts underway to install and evaluate the system at the Denver area and Dallas/Ft. Worth area air traffic control facilities. This paper will review CTAS architecture, and automation functions as well as the integration of CTAS into the existing operational system. CTAS consists of three types of integrated tools that provide computer-generated advisories for both en-route and terminal area controllers to guide them in managing and controlling arrival traffic efficiently. One tool, the Traffic Management Advisor (TMA), generates runway assignments, landing sequences and landing times for all arriving aircraft, including those originating from nearby feeder airports. TMA also assists in runway configuration control and flow management. Another tool, the Descent Advisor (DA), generates clearances for the en-route controllers handling arrival flows to metering gates. The DA's clearances ensure fuel-efficient and conflict free descents to the metering gates at specified crossing times. In the terminal area, the Final Approach Spacing Tool (FAST) provides heading and speed advisories that help controllers produce an accurately spaced flow of aircraft on the final approach course. Data bases consisting of several hundred aircraft performance models, airline preferred operational procedures, and a three dimensional wind model support the operation of CTAS. The first component of CTAS, the Traffic Management Advisor, is being evaluated at the Denver TRACON and the Denver Air Route Traffic Control Center. The second component, the Final Approach Spacing Tool, will be evaluated in several stages at the Dallas/Fort Worth Airport beginning in October 1993. An initial stage of the Descent Advisor tool is being prepared for testing at the Denver Center in late 1994. Operational evaluations of all three integrated CTAS tools are expected to begin at the two field sites in 1995. Derived from text

In order to be able to investigate various aspects of the complex Air Traffic Control (ATC) system of the future, a real-time ATC simulation facility has been constructed at NLR. The ATC automation environment of this simulator is provided by CTAS, the Center/TRACON Automation System, developed by the NASA Ames Research Center. For the simulation of air traffic, radar observations, and data link, the NLR ATC Research Simulator (NARSIM) is used. The facility can be used at various levels of automation, ranging from conventional, 'manual' ATC to fully automatic control. For the latter, CTAS has been extended with various decision and control algorithms, dealing with tasks normally executed by the air traffic controller. In a set of real-time simulation experiments different concepts of fully automated ATC are investigated, characterized by various combinations of control functions and different levels of air-ground interaction. Furthermore, the effect of different levels of aircraft navigation performance is studied. The traffic samples are based on single-runway IFR operations for Schiphol Airport, with the traffic mix and distribution based on predictions for the year 2000. The Dutch airspace is simulated with one overall area control sector, controlling traffic from all directions to the three arrival gates, and one Schiphol approach sector, merging the aircraft from these gates into a properly spaced sequence on final approach. For the analysis of the simulations, methods are under development to present overall ATC system performance in terms of safety, flight efficiency, capacity, and control performance. The results of the simulations are used to determine critical areas in ATC system automation, as well as potential benefits thereof. They can also contribute to an optimal distribution of tasks between man and machine in the ATC system of the future. Author (revised)

This paper covers the potential of Decision Making Aids to be implemented before the year 2000 and, within the time frame considered, covers all of the aspects of automated assistance, based on flight path prediction and monitoring, which help air traffic controllers to establish and assess the predicted traffic situation more efficiently. Problem detection, problem minimization, and 'best next clearance' advisories will permit the reduction of the controller's mental workload without decreasing the level of safety or the controller's situational awareness. The central problem of this investigation is the creation of an Air Traffic Control System (ATC) involving both man and machine. The present document reports on two examples which typify the man-machine relationships in systems which are partly automated. In one case, the part played by the machine is detrimental to man's involvement; in the other case, man and machine work together for better results. The manner in which this second approach was used during the development of the CENA's ERATO project is described. Transl. by FLS

Considerations on the design of graphical user interfaces (GUI's) for air traffic controllers are presented in the context of a European Air Traffic Management System (EATMS). The fundamental issues discussed include the following: air traffic controller tasks; human information processing and mental models; and automation strategies with respect to the GUI design. The more specific issues of GUI design which are also discussed include the following: GUI programming environments and standards; development tools; design principles and human factors/human engineering standards; and usability testing. Conclusions are drawn regarding the current background of GUI design with respect to an EATMS and necessary future developments. Author (revised)

Since 1989, the Institute for Flight Guidance of the German Aerospace Research Establishment (DLR) has been developing prototypes of interactive tools in close cooperation with the German Air Navigation Services (DFS) in order to achieve gradual improvements in the efficiency and productivity of the air traffic

control system. The paper briefly describes the potential of a selection of analysis and planning tools that have been developed in this framework. After an introduction into the 'planning world' of tactical and strategical air traffic planning, the objectives and potentials of four tools will be demonstrated as applied to real traffic scenarios and actual problems of the current ATM system.

Due to increases in air traffic volume and the evolution of operational missions, Alcatel ISR has been awarded a contract to analyze the requirements of military air traffic controllers, especially in the area of the air situation interpretation and the implementation of a mock-up. DAISY is aimed at providing controllers with a decision aid for an air situation interpretation system. In this context, interpretation stands for all the rules and combined information which give an operational meaning to the air situation. Abnormal situations are highlighted, a diagnosis is given, and a proposal is made for decision. After a requirements analysis is conducted, both by experts and controllers during six months, a twelve-month technical feasibility study was led by Alcatel ISR, and a mock-up was developed dealing with typical interpretation scenario such as trajectory prediction. The Institute for Flight Guidance of DLR is involved in medium and long term research and development of concepts, procedures, functions, and components for a future integrated Air Traffic Management System. The medium term work concentrates on improvements concerning the capacity of Frankfurt airport. This paper describes a planned demonstration program which is designed to prove concepts and tools developed by the Institute in cooperation with the German ATC Authority (DFS) and the operator of Frankfurt airport (FAG) as well as with PHARE. The aim of these experiments is to demonstrate the feasibility and merits of integration of onboard avionics with advanced ATC systems on the ground. For this purpose an Air Traffic Management Demonstrator System will be employed, which comprises an air segment and a ground segment connected via an automatic data link and voice communication. The demonstration program will be performed in several phases comprising simulation runs in an air traffic simulator as well as flight tests with a real aircraft.

(AGARD-CP-538) Copyright Avail: CASI HC A03/MF A04

A time-based air traffic control (ATC) system where vehicles are sequenced on desired time of arrival (TOA) has been proposed as one way that might help increase airport capacity. This paper evaluates three time-based ATC system concepts: (1) ground based (computing trajectories on the ground), (2) aircraft based (computing trajectories on the aircraft), and (3) ground and air based (generating parametrized velocity and acceleration profiles on the aircraft and transmitting them to the ground where trajectories are recomputed). The parameters compared are amount of database, complexity of communications, computational requirements, autonomy of aircraft, and similarity to current procedures. The ground-and-air-based approach using parametrized profiles has the best potential for providing a high-landing-rate ATC system with minimal processing and communications requirements. In this approach, ATC assigns time slots at the metering fix based on desired time of arrival (TOA) and range-TOA windows generated on the aircraft. The aircraft sends a simple set of parametrized deceleration and velocity profiles to the ground. The ground processor uses these profiles to generate trajectories and identify conflicts. The ground processor resolves conflicts by examining nearby trajectories using both the sets of parametrized deceleration and velocity profiles and the range-TOA windows. The new horizontal plan and the new profile parameters are sent to the aircraft, where the aircraft flight management system (FMS) regenerates the trajectory and precisely flies it. The advantages of such a system are that it is a natural extension of the current system; it does not require massive ground databases of aircraft thrust, drag and FMS models; it uses a ground processor generating simple models to examine and resolve conflicts; it requires only one air-to-ground interaction; and the aircraft is autonomous. A simulation was used to evaluate the concept. The models used in the simulation are ATC trajectory generator, aircraft FMS, aircraft path controller, and vehicle motion. Multiple-aircraft scenarios, starting in cruise and descent, were examined. Factors examined were separation distances between aircraft on different approach trajectories, accuracy of TOA, and effects of wind-forecast errors on TOA errors. Author

OPPORTUNITIES FOR INTEGRATING THE AIRCRAFT FMS, AERONAUTICAL OPERATIONAL CONTROL CENTERS, AND FUTURE AIR TRAFFIC MANAGEMENT SYSTEMS IN OCEANIC AIRSPACE
CLYDE MILLER, BILL BLAKE, JOHN SORENSEN, and JOSEPH MILLER *In* AGARD, Machine Intelligence in Air Traffic Management 10 p (SEE N94-29558 08-04) Oct. 1993

Rapid technological changes are taking place in the aviation system user facilities - both on the aircraft flight deck and at the aeronautical operational control (AOC), or flight dispatch centers. On the flight deck, the flight management system (FMS) is bringing capability for precise three-dimensional guidance, flight path optimization, and speed control to meet required time-of-arrival (RTA) constraints at key route waypoints. This is enhanced by the precision global navigation satellite system (GNSS), use of digital datalink for communications, and automatic dependent surveillance (ADS). At AOC facilities, advancements in flight planning, flight following, weather information and datalink allow the dispatcher greater flight operations management capability over the airline fleet. This is especially significant for oceanic airspace operations. In parallel, the oceanic air traffic management (ATM) system is undergoing an evolution in automation that will enhance the overall aviation system productivity. Much of the information that each of the three system components - flight deck/FMS, AOC, and ATM - have would be very useful to the other two components for flight efficiency and overall productivity enhancements. Worldwide datalink technology will provide a universal and reliable data communication capability between these components to allow this information sharing. This paper discusses the opportunity to integrate the functions of the FMS, AOC, and ATM computers by exploiting the capabilities of worldwide ground and air data link. First, the outstanding needs of both the oceanic airspace user and traffic management provider are stated. Then, the emerging technological capabilities of ATM automation, FMS and AOC are summarized. This is followed by explicit operational applications where the integration of these capabilities can bring incremental benefits to flight efficiency and human productivity. Needs of both the airspace user and air traffic management service provider are addressed. Operations using today's organized oceanic track system as well as the future free route system are discussed. The opportunities for FMS-AOC-ATM integration are illustrated by three scenarios for oceanic operation. These include a mid-oceanic route replanning task to respond to weather change, a passing maneuver to allow more flexibility in flight speed and altitude when flying along a track system, and use of the FMS RTA capability to meet scheduled track entry gate times with precise accuracy.

NASA Ames Research Center and NASA Langley Research Center conducted a joint simulation study to evaluate a profile negotiation process (PNP) between a time-based air traffic control ATC system and an airplane equipped with a four dimensional flight management system (4D FMS). Prototype procedures were developed to support the functional implementation of this process. The PNP was designed to provide an arrival trajectory solution that satisfies the separation requirements of ATC while remaining as close as possible to the airplane's preferred trajectory. The Transport Systems Research Vehicle cockpit simulator was linked in real-time to the Center/TRACON Automation System (CTAS) for the experiment. Approximately 30 hours of simulation testing were conducted over a three week period. Active airline pilot crews and active Center controller teams participated as test subjects. Results from the experiment indicate the potential for successful incorporation of airplane preferred arrival trajectories in the CTAS automation environment. Controllers were able to consistently and effectively negotiate nominally conflict-free trajectories with pilots flying a 4D-FMS-equipped airplane. The negotiated trajectories were substantially closer to the airplane's preference than would have otherwise been possible without the PNP. Airplane fuel savings relative to baseline CTAS were achieved in the test scenarios. The datalink procedures and clearances developed for this experiment, while providing the necessary functionality, were found to be operationally unacceptable to the pilots. Additional pilot control and understanding of the proposed airplane-preferred trajectory and a simplified clearance procedure were cited as necessary for operational implementation of the concept. From the controllers' perspective, the main concerns were the ability of the 4D airplane to accurately track the negotiated trajectory and the workload required to support the PNP as implemented in this study. This paper provides a general introduction into the Programme of Harmonised Air Traffic Management Research in EUROCONTROL (PHARE). It describes the objectives of the research program and addresses the benefits of the integration of the automated systems onboard the aircraft with those of the ATC systems on the ground using a digital air-ground data link. The assumptions on the expected infrastructure and environment are explained and the possible automation and air-ground negotiation strategies discussed. Finally descriptions of the experimental facilities available or under development and of the planned experiments are provided. Author

The Programme for Harmonisation of ATM Research in Eurocontrol (PHARE) has undertaken to perform the required research work necessary for the introduction of advanced ATM. Within this PHARE framework, it is the task of the PHARE Advanced Tools (PAT's) group to develop the appropriate automation and communication tools to support the air traffic controller. Although the principles for computation, prediction and control of air traffic trajectories are well developed, the various future ATM scenarios reflect different views on the way automation and communication technology can best be applied. The consequence of this is that PHARE research has to be directed towards multiple ATM scenarios, and that the PAT's to be developed should be applicable to automation and communication under different ATM scenarios. The paper gives an overview of the approach taken by the PAT's group in facing this challenge. Author

The Common Modular Simulator (CMS) project is part of the Program for Harmonized ATM Research in Eurocontrol (PHARE). The main objective of this project is to provide a common integration environment which shall allow the creation of a homogeneous infrastructure in order to facilitate and harmonize the development as well as the evolution of ATM simulators in the different research establishments. To meet such an ambitious objective, CMS partners have adopted a system architecture based on a client-server model with active servers providing event subscription and event notification mechanisms. The main advantages of such client-server models are to offer a very modular system architecture and to provide, through the associated application programming interface (API), a very powerful mechanism of abstraction. This leads to a very flexible, evolutive, open, scalable and adaptable system. CMS will offer an architecture test bed for future advanced ATM systems. As a consequence, this project should be of great benefit to many other ATM projects. Author (revised)

The 'Studies, Tests, and Applied Research' (STAR) program of the EUROCONTROL Agency is addressing several implementation timescales for air traffic management (ATM) systems and procedures. ARC2000 (automatic radar control 2000) is presently the major long-term component of the STAR program, for implementation beyond 2015. ARC2000 is addressing the enroute ATC capacity issue, which is severe in Europe, by investigating the limit case where both major constraints, workload and sectorization, are eliminated. It is often easier to solve a complex problem by first looking at the limit case. ARC2000 could not be implemented as such, but should provide precious information with respect to feasible levels of automation in the long term. There are also significant by-products which will speed up shorter term research. Indeed, ARC2000 provides a 20-30 minute conflict-free planning which is a key feature of the European Air Traffic Management System (EATMS) concept.

Modern high precision navigation systems based on satellite and inertial navigation provide a positioning accuracy that has never been achieved before, for aircraft enroute as well as during approach and on the airfield. By using such combined accurate positioning systems it is possible to guide aircraft on the ground and to perform automatic taxiing, which further increases the safety of ground operations. Whenever high precision terrestrial navigation is needed, common aeronautical navigation displays are not able to provide the information, which easily can be combined with the pilot's view from the cockpit, to deliver the necessary guidance aid. A flexible map display is desired to be shown in the cockpit. The new taxi guidance system GINaS, presented in this paper, is based on an integrated navigation system (DGPS/INS) and a digital map using only the standard display and navigation hardware of modern commercial aircraft. The system was successfully tested in one of our testbeds, a van. This van can be driven automatically by the system as well as by the pilot using the information of the digital map and a drive-director. The accuracy reaches submeter level. Author (revised)

In the modern world there is an increasing need for surveillance, and a consequent need for automatic or semi-automatic methods for processing dynamic input data and presenting it in a form which is useful to the end user. This paper outlines advanced knowledge-based techniques for monitoring such data. The techniques have been applied to airport ground traffic applications and demonstrated in particular on data from actual turn-round scenarios for stand area servicing of an aircraft as observed by a single camera. Results are output in real-time as a status report by an integrated system which is designed to handle the vagaries of real data in respect to incompleteness and uncertainty. The new techniques developed can also be applied to other ground movements surveillance applications which have multiple sensor inputs of the same or different modalities. Author (revised)

This contribution describes a radar network for airport surface movement guidance and control. The network comprises several low power radar stations which are organized in modules of four stations each. All antennas are staring and illuminating the area continuously. Moving objects are localized by range profile measurements and a subsequent multilateration. Each module runs autonomously. The module computer at the master station calculates the multilaterations and controls the communication with three slave stations. The measured data from these stations are transferred via the radar transmitters to the master station, while the multilateration and imaging results are sent via data cables to the central computer. There, the information from all modules will be merged and tracks will be constructed; furthermore, a classification process on the basis of the images will be executed. Author (revised)

This paper describes the results of a research program to investigate the use of advanced radar, display systems, and controller alert automation aid to increase capacity at airports with closely spaced parallel runways. Analysis has indicated that the runway spacing could be reduced without adversely affecting capacity if a surveillance radar of higher update and accuracy and a high resolution color display system with controller alert automation aid are used. This paper first describes a research program to demonstrate the feasibility of using a precision runway monitor (PRM) system for conducting independent simultaneous approaches to parallel runways spaced at less than 3400 ft (1035 m) apart. A PRM system consists of an improved radar system that provides high azimuth and range accuracy and higher data rates than the current terminal airport surveillance radar (ASR), a processing system that monitors all approaches and generates controller alerts when an aircraft appears to be blundering, and a high resolution color display. Two airports were selected to serve as the demonstration and test facilities of the PRM system. This paper describes the key elements of the demonstration program including test criteria and scenarios, controller and pilot/aircraft response times, and risk analysis. Results of the demonstration program on the feasibility of the 3400 ft runway spacing standards using PRM are presented. Recommendations on radar update rate, accuracy, and display requirements for the PRM system are summarized. This paper also describes the follow-on research activities to investigate further reduction of parallel runway spacing standards to below 3400 ft using the PRM system and advanced navigation and landing systems. Applications and extension of research results to triple and quadruple closely spaced parallel runways are discussed. Author (revised)

Following a summary of the activities of the Guidance and Control Panel of AGARD in the field of Air Traffic Handling, this volume constitutes essentially an introduction for those new to the Air Traffic Control Research and Development community, offering, on the one hand, a broad view of the present situation and actual limitations, on the other hand, some precise idea of a long term system objective. It is composed of a preface, a general introduction and ten chapters, each constituting an introduction to the corresponding topics, successively entitled: the air transport system, air traffic complexity, traffic evolution, electronic aids to controllers, arrivals management systems, decision making aids, a look further into the future, towards global optimization, systems evaluation facilities, and the airport of the future. Mutual couplings among the mathematical models of physical phenomenon and parts of a system such as an aircraft complicate the design process because each contemplated design change may have far reaching consequences throughout the system. This paper outlines techniques for computing these influences as system design derivatives useful in both judgmental and formal optimization purposes. The techniques facilitate decomposition of the design process into smaller, more manageable tasks and they form a methodology that can easily fit into existing engineering optimizations and incorporate their design tools. A new optimization based design method is discussed. This method is based on integrating existing disciplinary analysis and sensitivity analysis techniques by means of generalized sensitivity equations. A generic design system implementing this method is described. The system is being used to design the configuration and internal structure of a supersonic transport wing for optimum performance. This problem combines the disciplines of linear aerodynamics, structures, and performance. Initial results which include the disciplines of aerodynamics and structures in a conventional minimum weight design under static aeroelastic constraints are presented. Author

Wing analysis and design studies have been performed for the Validation of Aeroelastic Tailoring (VAT) configuration. The VAT represents a series of static and dynamic wind tunnel tests, performed in the 1970's, to verify the beneficial use of aeroelastic tailoring for fighter aircraft wing design. The VAT provides a useful database for evaluation of various aeroelastic methodologies. Static analysis predictions for ELAPS, a Ritz structural analysis code, are compared to the VAT results, with excellent agreement. ASTROS, a new multidisciplinary finite element optimization code, is also used for static and dynamic analyses of the VAT. The results demonstrate several analysis capabilities of ASTROS. The composite wing skin of the VAT is also optimized by ASTROS for strength and displacement constraints simulating aeroelastic loads. ASTROS was able to design the composite skin to achieve a desired twist and camber deformation behavior. ASTROS is thus a viable tool for aeroelastic tailoring design. Author

OPTSYS is a modular structural optimization system with well-defined interfaces to finite element (FE) programs and codes for aeroelasticity. A mathematical programming approach is adopted where a sequence of convex approximations of the initial problem is solved, using the method of moving asymptotes (MMA). This approach makes it possible to take all design criteria into account simultaneously. Gradients are calculated semi-analytically. OPTSYS can treat design variables associated to the shape of the structure, the element cross section properties, or the material direction in the case of composite materials. Constraints can be defined on displacement, stress, eigenfrequency, local buckling, flutter, and aileron efficiency. Recent developments have concerned the constraints on dynamic response and acoustics. Other important gradients are: the integration of a preprocessor to define shape variables, the treatment of discrete variables, and the possibility to deal with substructured FE models. The current status of the system capabilities and methods will be discussed and illustrated with applications on aircraft and automotive structures. Author

Prior to the development of the ECLIPSE system, structural optimization was performed by a combination of software and manual methods. These methods proved their worth by the reduction in costs and improvements in quality resulting from their use. The program used for optimization of structures subject to stiffness criteria became the focus for development of the aeroelastic constraints. This was later extended to incorporate strength constraints, fabrication constraints, and was coupled directly to the NASTRAN analysis system. This process of development continued with the result of the present general resizing, optimization, and post-processing system. This paper describes the application of the system to the optimization of three structures: tail plane, fin/rudder, and foreplane. The emphasis is on the use of the system to optimize for a flutter speed constraint in all three cases. However, in the case of the foreplane, the adaption of the system to include a detail stressing constraint is

illustrated. A brief description of some of the developments proposed for the future is also given. Author

A method developed for multidisciplinary design of aircraft primary surfaces to include buffet fatigue life improvements is presented. The method is a multistep approach. First, measured buffet pressures are used as the source of excitation. These pressures excite the primary structural modes of the tail and result in high dynamic strains. Second, the Automated Structural Optimization System (ASTROS) multidisciplinary code is used to either raise or lower the primary modal frequencies. Third, a NASTRAN random analysis is used to determine the buffet dynamic strains. Fourth, a subsequent fatigue analysis is used to compute the change in fatigue life. The process was demonstrated on a generic vertical tail. Author

The present paper is focused on findings and results of an integrated design optimization study for an aircraft fin. The basic flight mechanics design requirement for a vertical fin is to provide a specified control power inside the whole flight envelope with a minimum weight structure. A method of implicit function theorem has been applied on our MBB fin sample problem. The definition of state variables and independent variables will be discussed in detail. Three basic aerodynamic parameters have been chosen for the sensitivity analysis: taper ratio, aspect ratio, and surface area. This aerodynamic sensitivity analysis has been performed by the finite difference method. The necessary finite element models of the structure have been generated in the same way as the aerodynamic model for the finite difference method. The applied method based on implicit function theorem has proven its capability to provide a transparent method with clear defined discipline interfaces which are essential to monitor a complex system. Lecture notes for the AGARD Fluid Dynamics Panel Special Course on 'Engineering Methods in Aerodynamic Analysis and Design of Aircraft' have been assembled in this report. Proven engineering methods used during conceptual and preliminary design and development of new aircraft concepts are presented. These methods focus on simple computational procedures for conceptual and preliminary design, low level analysis computer codes, and experimental techniques for aircraft performance predictions. The course was aimed at helping train young engineers to appreciate and work with simple engineering tools to enhance the art of cost effective preliminary design of new aircraft. For individual titles, see N92-23951 through N92-23957.

There are three major statements that characterize the findings of this special course. First, engineering work in aeronautical analysis and design is traditionally performed both through experiments and through numerical analysis. Second, an interdisciplinary approach is mandatory in conceptual and preliminary design work because although experiments will not be replaced by computational fluid dynamics (CFD), CFD may complement experiments by allowing quicker and more reliable selection of promising configurations. Third, engineering methods are indispensable because: high level CFD analysis is excluded in preliminary design; experimental work may be unavailable for configuration conception; and empirical low level flow code analysis and extrapolation from previous experience is the only logical consequence. Preliminary design of aircraft has evolved largely over the past ten years. The main origin of the evolution came from the rationalization and broadening of the preliminary emphasis on new project development. The project has to be evaluated more quickly and the capability of a project to meet its requirements must be satisfied. This paper deals specifically with low level computations for preliminary design, and covers such areas as: center of pressure evaluation; lift evaluation; drag evaluation; air-intake integration; afterbody integration; and interactions with non aerodynamic requirements. An overview is presented of several aspects of panel methods used in the aerodynamic analysis and design of aircraft or aircraft components. Panel methods can provide the flow about complex configurations and are routinely used in the analysis of the aerodynamics of realistic aircraft shapes. However, panel methods are based on a mathematical model in which much of the fluid physics is ignored. The report discusses the capabilities and limitations of panel methods, the basic concepts of the panel method, choices that can be made in the basic implementation of the concepts, as well as possible types of boundary conditions that can be utilized to creatively model subsonic and supersonic flow. The discussion also includes aspects of the accuracy of the approximation, consistent formulations, aspects of low and high order panel methods, etc. Also discussed are the computational aspects of panel methods and possible extensions to nonlinear compressible flows, coupling with viscous flow methods, and applications to other flow problems. A collection of aircraft drag analysis methods and drag reduction techniques has been prepared. Pressure, skin friction (viscous), wave (compressibility), lift induced (vortex), interference, throttle dependent, and trim drag source predictions are included. The need to establish a computational drag prediction experience base is emphasized and illustrated. Project type applications are described in which these drag prediction tools have been implemented for drag reduction processes. The paper concludes by summarizing the role played by computerized drag prediction methods in aircraft design programs. Author

TECHNICAL EVALUATION REPORT ON THE FLIGHT MECHANICS PANEL SYMPOSIUM ON FLYING QUALITIES
HAROLD ANDREWS (Aviation Systems and Research, Arlington, VA.) Apr. 1992 22 p
(AGARD-AR-311; ISBN-92-835-0665-0) Copyright Avail: CASI HC A03/MF A01

The validity of constraining the responses of today's control dominant aircraft to conform to the classic flying qualities criteria derived from stability dominant aircraft experience has been an issue for many years. The introduction of full time visual scene enhancement with sensor fusion, and computer generated/interpreted night scenes, and the use of integrated flight and propulsion control schemes and direct force controllers have expanded flight envelopes, reduced drag, increased maneuverability, provided the framework for practical gust alleviation and active flutter suppression, and provided flexibility for fault-tolerant, damage-adaptive flight controls. However, the updating of flying qualities criteria has in general not kept pace with these technological changes. The Flight Mechanics Panel of AGARD therefore decided to organize a Symposium to review flying qualities issues today, and to report progress towards their resolution. The topic areas included: Flying Qualities Experiences on Contemporary Aircraft; Application of Flying Qualities Specifications; Flying Qualities Research and Flying Qualities at High Incidence. This Technical Evaluation Report evaluates the presentations and discussions in each session, draws relevant conclusions and makes recommendations for future activities in this area. The papers presented at this Symposium are published as AGARD Conference Proceedings 508. Author

The ALENIA Mini-Remotely Piloted Vehicle (RPV) System has the capability to perform different missions; one of the most useful missions is to provide real-time target acquisition (detection, recognition, identification and location) from the battlefield. When the target has been identified, the Mini RPV System within the GCS processes data arriving from the air vehicle and with the aid of digital terrain maps gives the target location by determining geographical coordinates and altitude. Target location is calculated using the vector from the air vehicle to the target and the RPV present position. The RPV to target vector information relative to air vehicle body coordinate is derived from sensor LOS data acquired using a stabilized platform. This platform permits target tracking irrespective of air vehicle motion. With present on-board electronics and digital terrain maps, the target location accuracy is approximately 50 meters CEP. Worldwide interest in the use of shipborne aircraft as a major weapons system is very broad. Many NATO countries operate fixed wing aircraft from ships. Additionally, the use of ships as helicopter platforms is extensive in the NATO community and brings another important dimension to the aircraft/ship interface issue. Thus, it seemed that both fixed and rotary wing aviation deserved equal billing in the Aircraft/Ship Interface Symposium which is the subject of this Technical Evaluation Report. The Symposium contained twenty-five presentations grouped under the following topics: Keynote Addresses; Ship Environment; Guidance, Controls, and Displays; Flight Test and Simulation Techniques; Launch, Recovery, and Handling Systems Development; and Operational Views and Future Developments. INTEGRATED DESIGN ANALYSIS AND OPTIMISATION OF AIRCRAFT STRUCTURES [L'ANALYSE INTEGRALE DE LA CONCEPTION ET L'OPTIMISATION DES STRUCTURES DES AERONEFS]

May 1992 88 p Lectures held in Pasadena, CA, 8-9 Jun. 1992, in Lisbon, Portugal, 22-23 Jun. 1992, and in London, England, 25-26 Jun. 1992

(AGARD-LS-186; ISBN-92-835-0675-8; AD-A255373) Copyright Avail: CASI HC A05/MF A01

There is a lack of precise information on the effectiveness of specific methods in generating optimum designs for realistic aircraft structures. In this situation it is difficult for designers to make decisions on which systems to employ for a given design problem and which developments to pursue. Thus, it is necessary for designers to be aware of the relative merits of the different methods currently used for the design optimization of advanced aircraft. This lecture series covers the methods available for the computer based design analysis and design optimization of aircraft structures. The lecture series deals with the principles and practices adopted to integrate the various factors which are considered in the design of advanced aircraft. These factors include: structural shape, aerodynamics, active control technology, and aircraft performance. For individual titles, see N92-28470 through N92-28474.

FUNDAMENTALS OF STRUCTURAL OPTIMISATION

A. J. MORRIS *In* AGARD, Integrated Design Analysis and Optimisation of Aircraft Structures 13 p (SEE N92-28469 19-05) May 1992

(AGARD-LS-186) Copyright Avail: CASI HC A03/MF A01

Structural optimization is concerned with the computerized automatic design of structures which are optimum with respect to some major design parameter. In the aircraft industry this parameter has usually been structural weight, though cost, performance, or other factors are now being considered. The general problem which is characterized here remains unchanged so that the basic nature of the optimization problem is the same for all applications. Also the structural optimization problem is always characterized by the finite element method (FEM). The use and application of these methods to computer aided design (CAD) requires some understanding of the underlying mathematical principles. It is shown that this process of developing solution methods use the optimization criteria as the basis for creating the up-date formulae which are the solution algorithm drivers. H.A.

The structural optimisation system MBB-Lagrange allows the optimization of homogeneous isotropic, orthotropic or anisotropic structures as well as fiber reinforced materials. With the simultaneous consideration of different requirements in the design of aircraft structures it is possible to reduce the number of iteration steps between design, analysis and manufacturing. Based on finite element methods for structures and panel methods for aerodynamics, the analysis with sensitivity includes modules for static, buckling, dynamic, static aeroelastic and flutter calculations. The optimization algorithms consists of mathematical programming methods and an optimization and analysis/sensitivity is the optimization model which leads to a very modular architecture. Typical application examples show the power and generality of the approach. Author

Mutual couplings among the mathematical models of physical phenomena and parts of a system such as an aircraft complicate the design process because each contemplated design change may have a far reaching consequence throughout the system. This paper outlines techniques for computing these influences as system design derivatives useful to both judgmental and formal optimization purposes. The techniques facilitate decomposition of the design process into smaller, more manageable tasks and they form a methodology that can easily fit into existing engineering optimizations and incorporate their design tools. MATHEMATICAL OPTIMIZATION: A POWERFUL TOOL FOR AIRCRAFT DESIGN

OTTO SENSBURG *In* AGARD, Integrated Design Analysis and Optimisation of Aircraft Structures 19 p (SEE N92-28469 19-05) May 1992

(AGARD-LS-186) Copyright Avail: CASI HC A03/MF A01

Formal mathematical optimization methods have been developed during the past 10 to 15 years for the structural design of aircraft. Together with reliable analysis programs like finite element methods they provide powerful tools for the structural design. They are efficient in at least two ways: (1) producing designs that meet all specified requirements at minimum weight in one step; and (2) relieving the engineer from a time consuming search for modifications that give better results, they allow more creative design modifications. MBB has developed a powerful optimization code called MBB-Lagrange which uses mathematical programming and gradients to fulfill different constraints simultaneously. Some examples depicting the successful application of the MBB-LAGRANGE code are presented. Also results of other optimization codes are shown. The paper closes with an outlook on how the optimization problem could be enlarged to include the shape and size of airplanes. Author

VALIDATION OF SIMULATION SYSTEMS FOR AIRCRAFT ACCEPTANCE TESTING

A. A. WOODFIELD *In* AGARD, Piloted Simulation Effectiveness 4 p (SEE N92-28522 19-01) Feb. 1992

(AGARD-CP-513) Copyright Avail: CASI HC A01/MF A03

There is currently a limited role for simulation in flight clearance of sub-systems in civil aircraft. However, the extensive use of simulation for manned space vehicle clearance shows the potential for simulation to join other rigs in flight clearance. There is a

serious risk that simulation could prove inadequate if there is no systematic validation program. Simulation is a complex integration of models of vehicles and the environment, physical sensation devices and the pilot. Any of these can be modified to compensate for inadequacies in parts of the simulation. This can be acceptable for training simulators but is not acceptable for clearance activities because the influence of such modifications cannot be predicted in situations that are not going to be tested in flight. These issues are discussed. Author

In accordance with the steady increase in bypass ratio and hence fan nacelle diameter of engines for modern transport aircraft, also the investigation of engine-airframe interference effects is of increasing importance. This covers not only the interferences between the wing and nacelle plus pylon bodies, but also the effects due to the presence of the engine jet flow field. In the low speed range of an aircraft, i.e., take-off, second segment climb, landing and roll out with thrust reversing, the jet interference investigations require wind tunnels with special high quality equipment, highly instrumented models with engine simulators and test setups outside the tunnel for special investigations. Concerning the different possibilities for engine simulation, the use of turbine-powered-simulators (TPS) has proven as the best and most flexible instrument. The paper presented here describes the technical progress made in the last years in testing techniques, based on close cooperation between Deutsche Airbus, Aerospatiale, DNW and ONERA. Further, a survey about the possible applications for low speed jet interference testing is given, mainly based on the Airbus A340 development program. Finally, some of these recent test results concerning performances and understanding of the aerodynamic and thermodynamic phenomena, especially concerning second segment climb jet interference, thrust reverser efficiency and plume reingestion effects are shown and discussed. It can be summarized, that a high level of technical test standard has been achieved and this together with a better understanding of the flow phenomena gives a viable basis for the integration of the coming generations of aircraft and engines.

The Fokker 100 is a twin engined T-tailed aircraft developed as a short to medium haul passenger and cargo transport. The engines are located on the aft fuselage. The development of thrust reversers on this type of aircraft was accomplished through different types of wind tunnel model tests and full scale tests. Model tests on an isolated exhaust configuration, scale 1:5, were conducted at Fluidyne in order to establish nozzle suppression and thrust reverser efficiency and side plume effects. Effects on directional and longitudinal stability characteristics were investigated by model tests on a complete mode, scale 1:12, in the LST of NLR. Reingestion tests were performed on the same complete model in the RR low speed facility at Hucknall. Attached photographs show the model in the NLR and RR facilities. This paper discusses the integration process, showing test results from wind tunnel model tests as well as full scale boiler plate and flight tests. A successful means to control side plume effects on the directional stability and a configuration change to suppress induced reverse plume empennage buffet is also discussed. Author

Performance improvement of the combat aircraft/engine unit rests on the optimization of intake/engine compatibility. This optimization requires specific flight tests in which the loss of the pumping margin of the compressors due to distortion is determined. The general methodology for the intake/engine compatibility analysis is described from the first wind tunnel tests to the flight tests. In order to determine the loss of the pumping margin due to the distortion of the air intake, an extensive instrumentation set was installed on the Mirage 2000 (Dassault Aviation) aircraft equipped with the M53-P2 (SNECMA) engine. The test procedures as well as the processing of the nonstationary signals are described. The correlations binding the nonstationary coefficients of distortion to the loss of pumping margin of the low pressure compressor are presented. It is shown that a correlation to only one parameter makes it possible to reach an accuracy of plus or minus 2 percent. On the other hand, the use of a correlation of two parameters (circumferential and radial) makes it possible to reduce the precision to plus or minus 1 percent. The use of an engine test stand in an altitude chamber with channels simulating nonstationary distortion makes it possible to reproduce in a satisfactory way the phenomena observed in flight and, in particular, to measure values of sensitivity to the distortion similar to the values obtained in flight. This method makes it possible to improve the optimization of the engine while reducing the number of flight tests. Transl. by FLS

A selection of topics has been made from the state of the art review in the Fluid Dynamics Panel Working Group 13 Report on Intakes for High Speed Vehicles. The first topic is a brief account of results from a program of research on internal and external flow in pitot intakes conducted in the UK over the period 1978-88. The main topic is that of intake airframe integration and is illustrated by examples from systematic work done in the USA and Europe on agile strike fighters and multi-intake missiles. Author

Building on a survey conducted in 1984 of the state-of-the-art of experimental and computational tools used to evaluate aerodynamic nozzle/airframe integration, this paper critically re-assesses these techniques in 1991. For experimental techniques, there have not been significant developments in the intervening seven years, and these mature techniques still serve the design engineer well. On the computational side, Euler techniques are now being applied as design tools in nozzle problems where there are not strong viscous interactions. Computation of the viscous regions, especially the nozzle boattail, with Navier-Stokes algorithms is still lacking. Author

The STOL and Maneuver Technology Demonstrator program has achieved its original goals established to demonstrate the benefits of thrust vectoring and reversing on a fighter aircraft. It has been shown that thrust vectoring will enhance up-and-away aircraft maneuverability at low speeds and can be used to improve tracking and capture tasks plus contribute significantly to improve takeoff performance and rough or damaged runway operations. Thrust reversing has been shown to permit quicker changes in energy states that could provide an advantage in tactical arena and can greatly reduce landing distances. It was also demonstrated that an integrated flight and propulsion control system that incorporates the appropriate control laws can significantly simplify pilot workload during all vectoring and reversing operations, including the approach, landing, and stopping tasks. Results of this program are being used to transition these proven technologies into future fighter systems. Author

This paper is a FDP contribution to the 79th symposium on 'Airbreathing Propulsion for Missiles and Projectiles' being held from 11-15 May 1992 in St. Medard-en-Jalles, Bordeaux, France. It presents an overview of the main findings of the last FDP meeting during 7-15 Oct. 1991 in Fort Worth, TX, USA on the subject of the title of this review paper. The meeting was structured in six sessions, one of them having been organized and chaired in form of an invited session by PEP contributions. Each session will be reviewed separately in this paper and conclusions (in some cases recommendations for future AGARD activities) are made based on the major outcome of the sessions including contributions and comments from the auditorium after the presentations or from the closing Round-Table-Discussion at the end of the meeting. It has been clearly demonstrated that the subject of the symposium is a highly interdisciplinary effort, which overlaps the terms of reference of both AGARD Panels, FDP and PEP to a large extent. This is specifically true for major components of the propulsion system like the air intake and the nozzle. Both experimental and computational techniques for analysis and design used during the engine/airframe integration for all kinds of flight vehicles have been reported. Author

It is considered by the Flight Mechanics Panel of AGARD as vitally important that the NATO flight test community meet regularly so that new techniques for flight test, instrumentation and data analysis and lessons learned from past and on-going programs be disseminated to ensure that safe efficient cost-effective and timely testing is accomplished. There are many new systems being tested or planned for testing in the near future. These include programmable signal processor radars, integrated flight, fire and propulsion control systems, thrust vectoring, low observable technologies, multifunction pilot displays and multisensor integration. Acquisition and processing of large quantities of avionics multiplex data are challenges that must be met. There is a need for greater use of simulators and other hardware-in-the-loop ground test facilities. For individual titles, see N93-19902 through N93-19930.

The development of new aircraft requires very heavy investments. Among these investments are the flight tests. Even if the flight tests correspond, on the average of 8 percent of the development cost, an economical approach should be taken. This is what Aerospatiale tried to do for nearly 3 decades on the main base of Toulouse Glagnac. The present development situation is described. Author

A brief historical review of accidents was made to examine lessons learned in flight testing with major emphasis on human factors limitations. The results of this survey show undeniably that new aircraft and new pilots are not immune to old problems. Of three related human factors limitations, pilot skill frequently showed up as the primary factor responsible for accidents due to inadequate training (or proficiency) to handle an unexpected situation. A primary contributing factor was unsatisfactory aircraft handling qualities which increased pilot work load and therefore were less forgiving to 'pilot error,' particularly when flown in a stressful situation at the extremes of the flight envelope. Historically, pilot induced oscillation (PIO) has persisted as a major control problem particularly in first-flight operation. Deliberate errors involving a conscious decision to 'take a chance' by flying an aircraft with known deficiencies occurred more frequently in early times. Finally, inadvertent errors involving forgetfulness, indecision, and confusion are occurring more frequently with the current trend toward automated computerized controlled cockpits. Author

The Lockheed Aeronautical Systems Company, teamed with the General Dynamics Fort Worth Division and Boeing Military Airplanes Company, designed, built and flight tested two YF-22A Advanced Tactical Fighter (ATF) prototypes which were powered by new prototype high thrust-to-weight ratio engines. The YF-22A design optimized the blend of low observability, maneuverability and supersonic performance. These design goals were achieved with the incorporation of many new and innovative technologies including thrust vectoring, integrated flight and propulsion control, internal weapons carriage, and composite materials. An advanced cockpit with colored liquid crystal displays, finger-on-glass controls and advanced avionics architecture was also incorporated in the prototypes. The YF-22A Demonstration/Validation (Dem/Val) flight test program was completed on the 28th of December 1990. Seventy-four flights for a total of 91.6 flight hours were accumulated on both prototypes. The first flight of YF-22A No. 1 was made on 29 September 1990, the second prototype flew on 30 October 1990. The primary objective of the Dem/Val flight test program was to demonstrate the airplane's capabilities. This approach, which prioritized the use of the aircraft as demonstrators over their use as development tools, was considered to be the most efficient method of generating the test data required for the Engineering and Manufacturing Development (EMD) proposal. The purpose of this paper is to briefly describe some of the YF-22A's unique design features and the Dem/Val flight test program. Author

The MB-339 is a proven jet trainer developed by Aermacchi in the late '70s, operational within the Air Forces of 8 Countries. In order to keep pace with the increasing needs in the training syllabus mainly related to the systems management, Aermacchi launched the development of the 'C' version, equipped with an integrated, digital NAV-ATTACK system. The development program was mainly company-funded, so that a 'modular' approach to the test was adopted in order to allow the validation of the design and the achievement of operational clearance, in accordance with the needs of freezing HW/SW configuration as soon as possible on one side and to maximize the results of the agreed flight test programme on the other. A further significant activity carried out in the same time has been the ASC (Airborne Strain Counter) development, a system designed in order to satisfy the need of the Italian National Aerobatic Team for an adequate monitoring of the structural fatigue accumulated on their aircraft. Finally, Aermacchi (with Oto Melara under a contract with the Italian Ministry of Defense) is completing the program for the integration on the MB-339 of an antiship missile aimed to demonstrate the operational capability and flexibility of the aircraft. Aermacchi's particular approach to flight tests, consisting in having the flight test engineering function distributed within all technical department branches and therefore eliminating the separation between design and test engineering, provided positive results in the whole development process. Purpose of the paper is to present the characteristics of the test program carried out, to highlight the factors that allowed the full achievement of the objectives and to provide an outlook of the characteristics of the aircraft systems. NASP - The National Aero-Space Plane - is a look into the future. It is a vision of the ultimate airplane, one capable of flying at speeds greater than 17,000 miles per hour, 25 times the speed of sound. It is the attainment of a vehicle that can routinely fly from earth to space and back, from conventional airfields, in affordable ways. It is the achievement of major technological breakthroughs that will have an enormous impact on the future growth of this nation. Most of all, it is a projection of America at its best, at its boldest, at its most creative. NASP is more than a national aircraft development program, more than the synergy of revolutionary technologies, more than a capability that may change the way we move through the world and the aerospace around it. NASP is a revolutionary technical, managerial, and programmatic concept; it is a possibility of what can be in America. The NASP program can be described in a number of ways: technological, programmatic, utilitarian, and conceptual. In each case, NASP has departed from the traditional evolutionary path. In order to achieve the vision of NASP, innovative and revolutionary approaches are required. The technical challenges require the synergism of several major technology breakthroughs. The programmatic challenges require a fundamental change in the development, management, and implementation of this strategic, high-tech program. The utility challenge requires a transformation of our thinking about aeronautical and aerospace systems. The conceptual challenge requires a paradigm shift in national planning, collaboration, and commitment. Each of these challenges, and the NASP response to them, is explored in the following pages. This paper describes the activities carried out at the ALENIA Flight Test Center in order to investigate the high angle of attack characteristics of the AM-X. Before starting with the flight tests, vertical wind tunnel and rotary balance facilities have been used to collect all the information on aircraft behavior at stall, behind stall and in developed spin, in order to efficiently and safely approach the flight test activity. Flight tests have been tailored for the primary role of this A/C: the ground attack. Flight trails were firstly devoted to the combat configuration to assess the A/C capability to perform safe defensive maneuvers at high angle of attack. Then, a number of external stores key-configurations were tested to verify the A/C capability to safely perform vigorous maneuvers as required for such a light attack aircraft. Finally the twin seater behavior, clean and with stores, has been investigated. Analysis of the tests results provided the confidence for further investigating on developed spin characteristics and for the A/C qualification to intentional departure in a defined envelope for training purposes. In November 1991 after about one year of successful conventional flight testing, the X-31A research aircraft no. 2 was taken to more than 30 degrees angle of attack for the first time. Since then a maximum angle of attack of about 53 degrees in 1-g flight has been achieved. This is the first time a dedicated post stall aircraft design has entered flight test beyond stall angles of attack. This paper summarizes descriptions of the control law characteristics of the X-31A and describes the flight test approach followed to safely expand and explore the high angle of attack and post stall flight regime. Furthermore, preliminary handling qualities test results obtained from the initial post stall envelope expansion are presented. Author

The automated analysis of flight test data depends on an indicator of when an atmospheric event, or flight maneuver, starts and ends. We use as indicator the disturbance intensity, which is defined as the relative lift change, and can be related either to aerodynamic or flight dynamical parameters. A number of flight test data records, obtained using the Portuguese CASA 212 Aviocar flight test aircraft, are analyzed to show how the start and end of a maneuver are signaled by the disturbance intensity. The latter is a possible objective measure, for a proposed scale of passenger/crew comfort, somewhat analogous to the Cooper-Harper handling qualities scale. Author

Flight testing of the X-31A post-stall experimental aircraft started in October 1990. Within the international 'Combined X-31A Flight Test Team', DLR contributes its system identification experience and capabilities for the determination of aerodynamic parameters from flight test data. The paper presents a brief description of the hard- and software for flight test data evaluation applied by DLR to support the X-31A project on-site. It describes the different steps of the data reduction and the models used for system identification. Selected results which were achieved mainly on the basis of data from flight test conducted for handling qualities investigations are shown and compared to wind tunnel predictions. The paper discusses the aspects of on-site system identification for flight test support, including the difficulties arising from working on a low-cost program. It is based on the experience made during the initial envelope expansion of the X-31A. Author

In three years of GPS (Global Positioning System) testing by the National Aerospace Laboratory NLR in the Netherlands, the complexity of the systems evaluated has increased considerably, from a stand-alone GPS receiver to an integrated navigation system in which GPS is one of the sensors. This paper describes in short a number of flight test programs carried out by NLR, namely (1) trials to investigate the suitability of differential GPS for precision approaches; (2) trials to determine the advantages of aiding a GPS receiver by INS (Inertial Navigation System) and of the use of null-steering antennas; and (3) trials to evaluate an in-house developed navigation filter in which three navigation sensors, GPS, INS and TRN (Terrain Referenced Navigation) were integrated. It is concluded that an integrated navigation system can offer a greater robustness and a higher accuracy of the navigation solution, taking into account the weaknesses the individual sensors have. Differential GPS can eliminate a number of systematic errors, improving the attainable accuracy. Author

An improved method of structural dynamic test design was developed at Kaman Aerospace Corporation over the past several years. The method, Generalized Force Determination or GFD, grew from experience using basic force determination during the early 1980's. Basic force determination was found to work extremely well for many types of fatigue test setups with limited matching criteria. In other tests, it was found that certain combinations of actuators and matching criteria would render the test rig impossible to calibrate. Basic force determination could not be used for those cases. Since then, the source of the difficulty has been identified, and fundamental theoretic foundations have been built by William G. Flannelly (of Kaman Aerospace Corp.) to generalize the process of force determination for essentially any type of fatigue test arrangement. In addition, GFD has grown into a complete, automated, turn-key software package which guides the test engineer to the best possible solution within the constraints of the available test hardware and provides concrete insight into ways of adapting the hardware arrangement to improve the solution even further. The theoretical foundations are presented in broad outline in this paper. The fatigue tests done on full scale SH-2 helicopters which verified the practical applicability of GFD are described also. The steps in the complete GFD system were honed by the practical knowledge gained during the conduct of these tests. Author

Detailed mathematical models of aircraft aerodynamics find their use in aircraft design evaluation, flight simulation, control system tuning, and aircraft certification. Unknown parameters in these models can be extracted from flight test data by means of a variety of system identification techniques. This paper shows how on-line aerodynamic model identification has become feasible by applying algorithms based on a decomposition of the state and parameter estimation problem and the application of a high speed multi-processor computer system. Results from a recent flight test program are presented. Author

A joint program between CAE Electronics Ltd., Montreal, and the Flight Research Laboratory, NRC, was conducted to develop high fidelity simulator models of the Dash 8 Series 100 and 300 aircraft. This paper focuses primarily on the Series 100 program. The flight test portion of the program entailed a relatively limited set of instrumentation due to aircraft ownership and regulatory constraints. The primary measurements were the basic inertial quantities and flight path reconstruction techniques were used to generate the time histories of other required flight path parameters (such as angle of attack and sideslip). The major portion of flight test data was analyzed using Maximum Likelihood Estimation with reliance on trim condition data for initial model estimates. The final simulator model was validated using specifically designated maneuvers conducted solely for validation purposes. Author

Since its founding in 1952, the Advisory Group for Aerospace Research and Development has published, through the Flight Mechanics Panel, a number of standard texts in the field of flight testing. The original Flight Test Manual was published in the years of 1954 to 1956. The Manual was divided into four volumes: (1) performance; (2) stability and control; (3) instrumentation catalog; and (4) instrumentation systems. This AGARDograph therefore describes the points that need to be considered when planning AAR trials to clear a new tanker or a new receiver aircraft for Service use. The paper assumes some familiarity with current AAR practices and equipment. It covers the two AAR systems in widespread use, namely the probe and drogue, and boom refuelling systems. Many of the points that need to be considered are common to both. Derived from text

The R5 wind tunnel allows the simulation of hypersonic flows at low Reynolds numbers, corresponding to intake conditions encountered at altitudes of about 60 km. The F4 wind tunnel is projected to study the effects of actual gas and especially effects associated with chemical kinetics during atmospheric reentry. Attention is given to the performance, installation details, and description of the introduction of wind tunnel testing. Author

Performance of aircraft structures has progressed in a sequence of steps during the past. Since composite materials have gained broad application because of significant technological improvement, it is timely to look for the next step in improvement of aircraft performance. It is very likely that this step is related to smart structures technology. Smart structures technology is able to meet various aircraft design objectives such as improved military aircraft effectiveness through improved aircraft capabilities and reduced life cycle cost or reduced direct operating cost of civil aircraft through improvement in performance, fuel consumption, and aircraft maintainability. Active/adaptive structures, structure health monitoring, and structure integrated avionics are the three areas which are felt to be the areas where smart structures technology is most beneficial. Ways for cooperation between various engineering and natural sciences, being a major driving force for the success of smart structures, are described as well as some laboratory scale experiments which were recently performed. It is felt that an increased effort in engineers in various fields towards realization of smart structures can be a new rewarding challenge for the aircraft industry in developing next generation aircraft. SMART MATERIALS FOR HELICOPTER ROTOR ACTIVE CONTROL
H. STREHLOW and H. RAPP *In* AGARD, Smart Structures for Aircraft and Spacecraft 16 p (SEE N94-11317 01-24) Apr. 1993

A major improvement of helicopter performance and comfort can be achieved by the implementation of rotor active control technology (RACT). The introduction of individual blade control (IBC) is a subject of current research activities. But the breakthrough of this technology is still missing due to the lack of appropriate rotating blade actuation systems. Smart materials may open a new possibility for the realization of rotor active control. A survey of current hydraulic individual blade actuation systems shows that these are very complicated and heavy. Blade actuation by smart materials offers the change for an electrical system integrated into the blade itself. A study of different blade actuation systems shows that in principle there is the possibility of achieving this goal. But, today the available materials are not ready for real 'smart' applications. The preferred materials - piezoceramics - show a too low tension strength and very low active strains. Therefore, at this time the only feasible blade actuation system for individual blade control seems to be a hinged flap at the outer third of a rotor blade. This flap can be controlled by a smart (piezoelectric) actuator. Estimations show that such a system will work on the desired yaw. Author (revised)

The findings of an investigation conducted under the auspices of The Technical Cooperation Program (TTCP) to assess the impact of active controls technology on the structural integrity of aeronautical vehicles and to evaluate the present state-of-the-art for predicting loads caused by a flight-control system modification and the resulting change in the fatigue life of the flight vehicle are summarized. Important points concerning structural technology considerations implicit in applying active controls technology in new aircraft are summarized. These points are well founded and based upon information received from within the aerospace industry and government laboratories, acquired by sponsoring workshops which brought together experts from contributing and interacting technical disciplines, and obtained by conducting a case study to independently assess the state of the technology. The paper concludes that communication between technical disciplines is absolutely essential in the design of future high performance aircraft. Author (revised)

Active control of an aircraft landing gear can give improved passenger ride quality during take-off and landing. The active control system studied uses feedback from airframe mounted sensors to modify rigid body and structural response. The system is based primarily on modifying the damping characteristics in the nose gear oleo. This is achieved by reducing the damping orifice area, with active control of the area about this new datum value. In addition, the benefits of a fully active nose gear using a separate supply of high pressure hydraulic fluid are evaluated. Significant benefits are demonstrated with the active damping control system compared with the basic landing gear. Responses to general runway roughness and discrete runway bumps are considered. The active damping control system is shown to be effective in reducing peak and rms passenger normal accelerations at all fuselage stations, particularly nose and tail. Good improvement can be obtained from active damping control of the nose gear, with no modification to the main gear. The first fuselage bending mode response can be reduced by active damping control. The benefits from the fully active system are marginal, considering the additional system complication. These effects are illustrated for a typical transport aircraft configuration. Author

Flexible wing technology was explored in a number of design studies. Wind tunnel experiments generally affirm the results of these studies that a flexible, variable twist wing holds the potential for dramatic air vehicle performance improvements. However, the attendant control reversal, increase in control parameter nonlinearities, and the need for an active control system to suppress flutter has discouraged the application of this technology in production designs. Advancement of a robust control capability for damping structural modes; embedded sensors to provide required inputs to the control system for active flutter control and, possibly, battle damage tolerance; high-speed on-board computation; and other technologies promise the capability to exploit the benefits promised by more flexible structures. Current proposals to reduce air vehicle structural weight are briefly reviewed and implications on the control system are assessed. Even though control system concerns exist, they are resolvable and it may be timely to undertake the development and demonstration of an actively controlled flexible wing. Author (revised)

NON-LINEAR FLIGHT DYNAMICS
P. GUICHETEAU *In* AGARD, Non Linear Dynamics and Chaos 13 p (SEE N94-18236 04-77) Jun. 1993 Sponsored in part by Services Techniques des Programmes Aeronatiques
(AGARD-LS-191) Copyright Avail: CASI HC A03/MF A02

In Flight Dynamics, aircraft motion is described by a set of non-linear differential equations, depending on parameters, associating the state vector (angle of attack, sideslip angle, speed, angular rates, etc.) with the control vector (motivators, etc.) through flight dynamics equations, aerodynamic model, and flight control system. Some works which aim at improving the knowledge and the prediction of aircraft behavior, in particular flight phases for which classical linearized analysis of non-linear differential equations is insufficient or not valid, are presented.

In the design of slotted flaps it is attempted to avoid a reacceleration between the trailing edge of an upstream element of the system and the peak velocity of the downstream element, to reach the maximum lift. It is proved that it is possible by means of a numerical procedure based on a vortex distribution. The resulting shapes are then discussed with reference to the application to a real design. Author

Tests have been carried out, on a combat aircraft model with high-lift devices, in the DRA Farnborough 5-meter pressurized low-speed wind tunnel. The deflection angle and position of a leading-edge slat were varied and optimum settings established. The separate effects of Reynolds number and Mach number on overall lift coefficient and on the optimum slat setting were investigated. The results show that optimum performance is achieved at a very high slat deflection angle and the performance is strongly influenced by compressibility effects. Author

An experimental investigation into scale effect at low speed and high lift has been carried out in the DRA 5-m, pressurized wind tunnel on a subsonic strike-fighter model equipped with slotted high-lift devices. The attachment-line boundary layer on the leading-edge slat was found to be turbulent on the outboard part of the wing near maximum lift for a range of unit Reynolds number. An adverse Reynolds number effect on maximum lift was measured

which correlated quite well with the onset of attachment-line transition. The conditions for onset of transition were not consistent with the assumption of gross contamination by the fuselage boundary layer, the attachment-line boundary layer remaining laminar on the inboard slat to more than double the expected free-stream Reynolds number. It is suggested that this result is due to spanwise variation in attachment-line position, which results in suppression of the disturbances emanating from the root region of the high-lift wing. It is concluded that attachment-line transition is a potentially significant factor in wind tunnel testing of high-lift wings equipped with leading-edge slats. Author

HIGH-LIFT RESEARCH: APPLICATION TO THE DESIGN OF THE ATR72 FLAP
P. CAPBERN *In* AGARD, High-Lift System Aerodynamics 10 p (SEE N94-18415 04-01) Sep. 1993
(AGARD-CP-515) Copyright Avail: CASI HC A02/MF A04

Due to slightly reduced Clmax objectives in landing configuration for the ATR72, compared to the ATR42, the high-lift system of the ATR72 is made up of a single dropped hinge flap, whereas the ATR42 was equipped with a double slotted vane type flap. Elimination of the vane has had a beneficial effect in greatly simplifying the high-lift system for the ATR72. This simplification has been achieved while ensuring that Clmax levels are maintained or improved at same flap deflection (up to the value required for landing), and take-off L/D ratio is improved, which has a direct repercussion on operational performance, such as minimum runway lengths and maximum take-off weight. This aerodynamic performance has been achieved thanks to the systematic introduction, since 1985, of numerical methods in the design phase, in addition to the empirical and experimental methods used almost exclusively until then. The ATR72 flap is indeed the first to be essentially designed with numerical methods at Aerospatiale. Beside this, more severe new regulations for turboprop A/C, leading to a restriction in the use of large flap deflections for the ATR42, the effect of the elimination of the vane on Clmax has been numerically investigated for this A/C. This study having shown promising results, some wind-tunnel and flight test verifications were conducted which confirmed the reliability of the numerical tools. The development of new design and analysis methods has been pursued; it has involved, on one hand, an extension of their field of use and the quality of the modeling, and, on the other, a reduction in the design cycle time. The objective was twofold: better optimization of high-lift systems, and, above all, an appreciable reduction in the associated design costs. Author

(AGARD-CP-515) Copyright Avail: CASI HC A02/MF A04

The flow around a 2-dimensional wing and flap is reviewed using inviscid and viscous computational fluid dynamic techniques. In particular, the effect of flap gap is explored. The results indicate that for optimum aerodynamic performance at low flap angles, flap gaps in the region of 2 to 3 percent are required. A novel 4-bar Fowler flap mechanism is described which is shown to give these required gaps for flap angles greater than 3 degrees. Such a mechanism can be readily optimized for minimum flap overlap at specified take-off flap settings. A comparison of a track and roller arrangement with the 4-bar mechanism indicates significant advantages for the latter. Author

The Boeing YC-14 was designed to perform a 400nm mission carrying a 26000 lb payload and land in 2000 feet on a semi-prepared landing strip. The high-lift system was one that had never been flown before; a upper surface blowing (USB) concept utilizing the 'Coanda' effect. The take-off and landing performance estimates developed from wind tunnel data were completely substantiated in the flight test program. The critical issue of continuing either a landing or takeoff after the loss of one of the two CF6 engines was also proven in the flight test program. The design details behind the performance of the YC-14 are discussed and some of the performance features of the airplane are explained. Author (revised)

This paper describes an on-going program of R&D into the development of high lift systems for future propeller driven regional transport aircraft. The work includes tests of two-dimensional airfoils and flaps, while half models are used for wing integration development. Comparisons are made between earlier commuter airfoil designs and advanced supercritical airfoils capable of NLF (natural laminar flow), using single and double-slotted flap systems in both cases. The advanced airfoils were also tested with a leading edge slat. Some effects of Reynolds number on lift characteristics are reviewed which show airfoils without leading edge slats were more sensitive at the scale of the half model used and that higher Reynolds numbers may be required. The advanced airfoils stalled at lower incidences than the commuter airfoils which are much thicker and better tailored to high lift performance. Advanced airfoils will likely require an additional flap segment to achieve similar lift to commuter airfoils. Leading edge slats gave large increases in maximum lift coefficients (up to 30 percent), which would allow substantial increases in wing loading if needed for the future. The half model development has entailed work on improving the sealing of the fuselage to the tunnel wall to minimize leakage. The paper provides some details of such work on high lift models and also on models used for cruise drag investigations. Author

CHOICE AND OPTIMIZATION OF A HIGH-LIFT SYSTEM FOR AN ADVANCED AMPHIBIOUS AIRCRAFT
M. A. AVERARDO, M. DELEO, and V. RUSSO *In* AGARD, High-Lift System Aerodynamics 13 p (SEE N94-18415 04-01) Sep. 1993
(AGARD-CP-515) Copyright Avail: CASI HC A03/MF A04

The design history of a flap system for an advanced amphibious aircraft is presented in this paper. All the most significant phases of the 2D theoretical studies and the experimental 2D and 3D investigations which have allowed to achieve the final geometry of the high-lift device will be described and, hence, the design criteria, the methods of analysis, the choices will be pointed out. Starting from the preliminary design of several flap systems, the development of this project needed a great deal of numerical studies and wind-tunnel tests in order to select, step by step, the most efficient geometries and to optimize the flap configurations. So, different technical aspects involved with these activities will be discussed: the choice of the flap types to be investigated, related to the special aerodynamic requirements of an amphibious aircraft and to the needs of other design areas (structure, weight, production); the geometrical elements effecting the aerodynamic performance of a high-lift device; general problems connected with theoretical and experimental studies of multi-body systems.

Integrated airframe design embraces the concept of bringing together all of the aspects of airframe design, including various disciplines such as structures, materials, aerodynamics, controls, and manufacturing, from conceptual design all the way through manufacturing. It also includes the sub-disciplines which are involved in each discipline and the interactions these have with one another. Moreover, an IAD process also affects the organizational structure of the personnel. In order to provide a broad-based approach to evaluating and identifying future research and development directions required to provide IAD technology, the First Integrated Airframe Design Technology Workshop, sponsored by AGARD, was held in Antalya, Turkey on 19-20 Apr. 1993. This document summarizes the output of that Workshop. For individual titles, see N94-24314 through N94-24327.

Recent advances in computer technology that are likely to impact structural analysis and design of flight vehicles are reviewed. A brief summary is given of the advances in microelectronics, networking technologies, and in the user-interface hardware and software. The major features of new and projected computing systems, including high performance computers, parallel processing machines, and small systems, are described. Advances in programming environments, numerical algorithms, and computational strategies for new computing systems are reviewed. The impact of the advances in computer technology on structural analysis and the design of flight vehicles is described. A scenario for future computing paradigms is presented, and the near-term needs in the computational structures area are outlined.

The successful and timely transition of new product technologies to weapon systems depends heavily on the technical maturity, flexibility, and cost effectiveness of the critical manufacturing processes and systems required to turn these technologies into tangible products. The whole concept of Integrated Product Process Development (a.k.a. Concurrent Engineering) encourages and facilitates the parallel design and development of these manufacturing processes and systems with the design and development of the product. As a result of new computer aided technologies and increased emphasis on manufacturing design, new tools and methodologies are emerging that will facilitate the early consideration of manufacturing in design. This paper will address the development of two such tools: Producibility Methodology; and Tools and Virtual Manufacturing. These tools will enhance the effectiveness of manufacturing engineers who are integrated product process development team members and enable design engineers to better understand the potential downstream implications of early design decisions.

The Integrated Structural Mechanics System (ISSY) is a modular structured tool used to perform a variety of different structural calculations on aircraft structures. ISSY integrates all model generation, analysis and evaluation programs used in structural mechanics under one user interface, and operates a common data base for all these programs. ISSY can be used to generate and analyze calculation models of structural assemblies (fuselage, wings, stabilizers, etc). This is performed by an interactive preprocessor implemented in ISSY. These calculations provide data for both the finite element analysis and for strength analysis, thereby avoiding redundancy of data. Model generation is supported by the use of parameterized standard models (and/or standard sub-models). In addition, model generation is made easier by comprehensive ISSY libraries which provide material data on aluminum, composites, in addition to geometric data on profile sections and rivet allowables. The geometry input data can be directly copied from the component loft data files. The model input data and calculation results are stored in relational data tables which can be analyzed by the postprocessor implemented in ISSY. In addition other modules convert conventionally generated calculation models into ISSY format and generate load case data. To aid partners work on international joint projects, ISSY is compatible with both standard NASTRAN and ISSY processed input and output data. A documentation of model and result data can be obtained in every phase of the justification report. Author

The process of designing aircraft structure requires many functional disciplines and associated interdisciplinary coupling. To achieve optimal performance, the various disciplines must work closely together and effectively exchange large amounts of pertinent data. In the past, this was accomplished either with independent analysis tools that were not tightly coupled or with a single analysis tool that lacked the required fidelity to truly support the needs of more than one discipline. In addition, the analyses were performed in series rather than concurrently. A major impediment to process improvement was the lack of a common geometry database that could be utilized by all disciplines required to support structural design. The rapid growth of computational capability and the gradual acceptance by engineers and management to the use of automated processes and common databases has allowed McDonnell Douglas Aerospace (MDA) to implement a concurrent engineering approach to structural design. Our present aircraft design process combines a common geometry approach and existing analysis tools with the power of engineering workstations to manipulate an integrated design database to arrive at an optimum design solution. Our modular approach divides the design process into smaller, more manageable tasks that can be performed concurrently. It achieves 'buy-in' from each engineering and manufacturing discipline by incorporating existing specialized design tools that have been developed by those groups and introduced into the process without taking away ownership. We use common geometry principles, neutral file structures, widely accepted third party and company proprietary applications coupled with consistent naming conventions and file management to achieve our integrated design methodology solution. The present system optimizes the vehicle structure for minimum weight against a given set of design requirements. It is currently used to evaluate advanced vehicles such as NASP and is also being applied to more conventional aircraft. In the future, capabilities will be added to this analysis system that allow it to be applied to detail design problems as well as increasing the fidelity of advanced design solutions. The major increase in capability will result from adding direct access to the computer aided design geometry and also in the incorporation of standard analysis checks into the system. We will design the architecture of the system such that new engineering and manufacturing applications can be easily added. This paper will discuss the evolution of the MDA integrated design methodology from the 80's to the present as well as our vision of the future. Author

Structural optimization software bears a great promise in multidisciplinary design as an effective way to find an optimal balance between the requirements from different disciplines. Due to the evolution of the airworthiness requirements and the increased complexity of aircraft systems it has become increasingly more difficult in the last few decades to establish the design loads. Thus, a clear need exists for quick and reliable load estimation procedures. The paper discusses some measures that can be taken to improve the load definition process. Finally, some examples of successful application of structural optimization software at Fokker Aircraft are given. The primary advantage of structural optimization software is that it aids a skilled designer in gaining a feel for the design space. It should aid the designer in his creative task instead of distracting his attention to using the software. This requires the software to be user friendly and to have built-in features for global and local sensitivity studies.

The high complexity of an active controlled civil transport aircraft design with its multiple interactions between the different disciplines was presented. It was highlighted that in future design of this kind, different design procedures have to be established with the target to reduce the dominance of one discipline by a multidisciplinary optimization process to ensure an overall aircraft optimum. This has the consequence that the data availability in a certain quality (stiffnesses, aero data, systems data) must be better synchronized with the needs of the user of these data (handling quality, system, loads, flutter, structures) and that cost functions are introduced in the beginning of the design work to ensure a balanced design. It is the firm belief of the authors that already this would be an important step forward. Active Control systems are rather easily capable of being integrated by having in mind to

use signals from additional sensors distributed over the A/C than are available from the ADIRU. There are some doubts that all these relations and interactions in real aircraft design can be replaced one day by a totally automated process but certainly more parts have to be put into a process chain to improve quality and safe design time. Current aircraft industry design practices produce high quality, safe, and affordable aircraft. However, future advanced and integrated methods offer the opportunity to significantly reduce the cost and development time of aircraft designs. This paper presents an overview of the current design process and an example for subsonic transport wing box design. It also describes a future process which is presently being implemented at the Douglas Aircraft Company, i.e. the Aeroelastic Design Optimization Program (ADOP), and its application to a similar subsonic transport wing. Specifically, stress and flutter are optimized and compression surface buckling and tension surface damage tolerance are integrated. Finally, the future direction of ADOP will be outlined which includes integration of aeroelastic loads, durability and damage tolerance, and concurrent structure and active controls optimization. In aeronautics, the age of high creativity, like the one in the fifties with the introduction of jet engines or the one in the thirties which started the age of monoplanes with metallic shell structures, is passed. Today, we are in a situation in which the final increment in basic performance (maximum speed, maneuver capability) is usually excessively expensive. It is now necessary to look to marginal areas to gain improvements in performance, to use new materials such as carbon fibers to tailor the structure to specific needs, and to simplify, with the help of electronics and servomechanisms, complicated mechanical systems to obtain aircraft architectures otherwise impossible to fly. But this is not enough; it is absolutely necessary to also improve the cost effectiveness by increasing the reliability, availability, and supportability of the weapon system, thereby reducing the usage cost and the production cost of the aircraft. This is not any more achievable using the single man capabilities on a single discipline, but it requires a new type of working organization which uses sophisticated means of calculation, integrated in order to optimize the overall design, and which compresses the time of the process by exploiting the synergism of the interdisciplinary couplings, overlapping as much as possible the design and manufacturing phases. Alenia Defense Aircraft Division, being involved in several programs, both by itself and in international cooperation, has followed this evolution and is actively pursuing the adequacy of its operative structure to the new requirements by adopting advanced technology processes. First, it is reminded that organization of airframe design is directly linked to the performances of available tools. As a matter of fact, they condition the number and nature of project iterations. The organization which should nowadays be recommended in view of the means of CAD, computation and mathematical optimization at our disposal is presented and analyzed. This leads to a first design, followed by experimental verifications with a key role for flight tests. The final design is checked with the help of calculations models calibrated on tests. Then the new tools which are the factors of future evolution of design methodology are examined: to dispose of 'Design History' corresponding to the whole data of the process; parametric CAD and shape optimization; multidisciplinary optimization; 'Feature' Design; improvement of computation methods. As a conclusion we insist on the fact that aircraft manufacturers, CAD suppliers, and scientific searchers will be well advised to create a dialogue as to future design methodology. Author (revised)

The phenomenon of Hot Gas Recirculation for vertical landing jet aircraft and the effect of exhaust gas ingestion on aircraft performance is described. Additionally, our experience with experimental modelling of HGR for aircraft configurations and the scaling of the important parameters is presented. The conflict between scaling the buoyancy of the flowfield and correct modelling of the pressure field is explored, and a number of fundamental experiments addressing this problem are related. It is shown that in the region close to the jets and when the aircraft is very close to the ground that there are quite large differences between the two scaling criteria; the near-field region requires full scale pressures for accurate representation. Away from this region, the Nozzle Pressure Ratio does not greatly affect the flowfield. Testing of a generic aircraft model with a number of different configurations shows that once near-field flowpaths have been eliminated the ingestion levels are underpredicted if the flow-field buoyancy is below full scale. Absolute levels of ingestion are not greatly different between the two scaling criteria, particularly with the large scatter in results which is endemic to the phenomenon. However, it is concluded that for practical configurations, i.e., those with low levels of ingestion, scaling of flowfield buoyancy is more correct than scaling of the pressure field. This method of scaling is appropriate for use in achieving a low ingestion configuration.

The flow field about a delta wing equipped with thrust reverse jets in slow speed flight near the ground has been computed. Results include the prediction of the flow about the delta wing at four fixed heights above the ground, and simulated landing, in which the delta wing descends towards the ground. Comparison of computed and experimental lift coefficients indicates that the simulations can capture at least the qualitative trends in lift-loss encountered by thrust-vectoring aircraft operating in ground effect. The STOL and Maneuver Technology Demonstrator (S/MTD) program was structured to investigate, develop and validate through analysis, experiment and flight test, four specific technologies

related to providing current and future high performance fighters with both STOL capability and enhanced combat mission performance. The four technologies are: (1) Two-dimensional thrust vectoring and reversing exhaust nozzle, (2) Integrated Flight/Propulsion Control (IFPC) System, (3) Advanced Pilot Vehicle Interface, and (4) Rough/soft field landing gear. In addition to the required technologies, all-moving canard surfaces were also incorporated into the baseline F-15B. As stated previously, the intent of the demonstration program was to validate specific technologies, it was neither a prototype nor an explicit research program. Starting with an existing aircraft, many wind tunnel tests were performed to define the incremental effects of the specific technology items. Thrust reversing was achieved by blocking the nozzle exit area and exhausting the flow through vane packs on top and bottom of the engine. In the Short Landing (SLAND) mode the engines were at full military RPM and all exhaust flow was diverted through final approach with the reverse vanes pointed aft to provide forward thrust. At touchdown, the vanes quickly swing forward to orient the exhaust flow to provide reverse thrust for the rollout. A significant amount of wind tunnel testing was devoted to measuring jet effects at all conditions but definition of jet effects in ground effect received particular emphasis. Reference 1 documented the development of the S/MTD configuration with details on the wind tunnel data and control laws. Data was presented on the jet effects in ground effect that were predicted. Special control logic was defined to mitigate strong nose-up pitching moments as thrust reversing was initiated after touchdown. A special ground-handling mode was also incorporated for the rollout phase. The flight testing produced some surprising results. The object of the present paper is to document that experience. Data will be summarized briefly for completeness. Pertinent flight test experience will be presented, with results of an innovative analysis technique developed by the contractor. Lastly, future requirements will be discussed. Author

The transitional flight characteristics of a geometrically simplified Short Take-Off Vertical Landing (STOVL) aircraft configuration were measured in the NASA Ames 7- by 10-Foot Wind Tunnel. The experiment was designed to provide detailed data for evaluating the capability of computational fluid dynamics methods to predict the important powered lift flow parameters. The model consists of a 60 deg cropped delta wing planform; a blended fuselage; and tandem, circular, high pressure air jets that exit perpendicular to the flat lower surface. Freestream Mach number is limited to a maximum 0.2. Model angle of attack ranges from -10 deg to +20 deg. The nozzle pressure ratios of both jets are varied between 1 and 3, and the jet exit temperatures are maintained at near ambient conditions. Detailed surface pressure measurements show that suction pressure peaks located on the upper surface of the wing during conventional wingborne flight for angles of attack greater than 5 deg move to the wing lower surface at angles of attack less than 0 deg. A reduction in these suction pressure peaks is observed when the lift jets are operating. With sonic jet exit conditions, a freestream Mach number of 0.14, and 0 deg angle of attack, the jet-induced suckdown is equivalent to a 3.7 deg reduction in angle of attack. Schlieren, laser light sheet flow visualization and total pressure measurements in the jet plumes provide a description of the three-dimensional jet efflux flowfield. Author

From previous AGARD activities, it was recognized that flying qualities and traditional aircraft performance parameters did not characterize the capability or effectiveness of combat aircraft, although they do offer a guide. Other expert groups had reached a similar conclusion. The subject that arose from these realizations was 'agility'. Recognizing that this was an incomplete or immature concept and that a wide variety of sometimes disparate views existed, the Flight Mechanics Panel formed a further Working Group, WG 19, consisting of specialists from AGARD member countries, to study the subject under the title of 'Operational Agility'. Working sessions were held at places of special interest to the group, between 1991 and 1993. The specific aims of the Working Group were to provide definitions, which are universally acceptable, of the terminologies involved in agility; to collate the results of lessons learned from experiments on agility; to define metrics or figures of merit for use in design and evaluation; to explore and document the theoretical foundations; to explore the operational pay-off of balanced capabilities between the airframe, systems and weapons; to highlight any specialized aspects applicable to rotorcraft; to indicate possible means of evaluation in flight; and to recommend areas for further research and development activities, including possible collaborative projects. The Group has completed its study of operational agility with this report. In undertaking the study, a greater understanding has been reached of those subjects which influence operational agility and how these subjects, via the use of operational agility concepts, may be related to the combat effectiveness of the weapon systems. In reaching this understanding, the Group has proposed definitions of the agility terminology which should prove universally acceptable; it has arrived at the methodology for assessment of the various component systems which contribute to the operational agility or combat effectiveness of a Weapon System; and has listed a number of major conclusions and recommendations. The importance of successful integration of a turboshaft engine into the recipient helicopter becomes ever more apparent as the market demands a product which is able to carry more payload, over greater distances, in a reduced time, with greater reliability, and at lower cost. New technology developments in individual vehicle systems alone will not be sufficient to ensure future competitiveness. Engine/airframe integration has a significant, previously neglected, role to play. Important direct performance improvements may potentially be exceeded by synergistic, spin-off benefits to other components. In some areas, such as stealth, adequate consideration of integration matters is becoming mandatory. The paper reviews some helicopter component technology directions and observes the implications of harnessing these technologies into integrated systems. Particular attention is paid to integrated intake and exhaust system designs as well as a more general look at overall vehicle integration. A final section discusses integration technology requirements and how they may be employed to produce a fully integrated airframe and engine design philosophy. Author

The methodology currently used in Sweden for fatigue management and verification of airframes is described. Applications from the new fighter aircraft JAS39 Gripen are included in order to illustrate the various concepts being considered. Additional experience from recent work on the older fighter 37Viggen is also included to highlight certain differences in the detail analyses, stemming from rather different nominal stress levels in the two aircraft. The present paper discusses the handling of load sequences and load spectra development, stress analyses and fracture mechanics analyses, fatigue crack growth modelling, component and full scale testing, service load monitoring regarding both the dedicated test aircraft, which is used to verify basic load

assumptions, and also the individual load tracking program developed for the new fighter. Author

Maintaining the structural integrity of aircraft depends on the initial definition of an inspection program to detect structural damage that may occur in service. Prediction of possible fatigue damage due to the applied loads and conditions of use encountered in service is based on an analysis of the probability of incipient cracks and on an evaluation of the development of undetectable faults assumed to exist between two inspections. The validity of evaluation models is generally demonstrated based on comparisons with results obtained on elementary test pieces subjected to predicted local load conditions in service and used to identify the influence of events such as rare overloads or frequent repetitive small loads. This paper presents the principles for processing in flight signals collected in order to predict structural damage by making in flight integrated calculations, considering influences such as: load signals precision (frequency of points taken); elimination of low amplitude variations; and cycle counting methods for the damage calculation. (AGARD-R-797) Copyright Avail: CASI HC A02/MF A03

During high angle-of-attack (aoa), less than 25 deg, the X-29 experienced severe vertical tail buffet. Fin tip accelerometer data exceeded 110 g's at approximately 16 Hz. The U.S. Air Force Flight Dynamics Directorate was asked to provide technical support to ensure that the entire X-29 flight test program could be safely conducted. The Flight Dynamics Directorate transitioned an in-house developed crack growth life prediction program to the X-29 program office and NASA/Dryden as well as extensive technical support. Three dimensional crack growth analyses were conducted between flight days to track possible damage growth based on actual strain data collected at critical areas of the vertical tail. The entire high aoa flight test program was completed as planned using MODGRO to predict damage accumulation. The data was used to manage flight maneuvers to maximize useful flight data and minimize structural risk. A follow-on flight test program was conducted with the X-29 to assess Vortex Flow Control. Repair to the tail was required to complete this mission. Analysis and verification testing of the repair was performed by the Flight Dynamics Directorate. At the end of that flight test program, less than 10 percent of the repair life was used.

The BAe Hawk family is designed primarily to UK regulations, including the safe life S-N fatigue philosophy. S-N data pertinent to key structural features was assembled at the design stage, and fatigue coupon/element tests were conducted in confirmation. The Hawk TMk.1 full scale fatigue test (FSFT) has continued to lead the RAF fleet, and the test loading has been validated by a major operational loads measurement (OLM) exercise. Incidents arising on the FSFT or in-service are handled by several approaches including S-N and fracture mechanics calculations, testing, statistical analysis, and modifications and/or routine inspections are introduced when necessary. The development of the fatigue life clearances of the BAe Hawk family is discussed with particular emphasis on the confirmatory testing and in-service loads measurement necessary to ensure and maintain fleet aircraft fatigue life clearance. REDUCTION OF FATIGUE LOAD EXPERIENCE AS PART OF THE FATIGUE MANAGEMENT PROGRAM FOR F-16 AIRCRAFT OF THE RNLAF
D. J. SPIEKHOUT *In* AGARD, An Assessment of Fatigue Damage and Crack Growth Prediction Techniques 11 p (SEE N94-34581 10-39) Mar. 1994
(AGARD-R-797) Copyright Avail: CASI HC A03/MF A03

Load monitoring of the F-16 fleet of the RNLAF is carried out by NLR using an electronic device capable of analyzing the signal of a strain gage bridge on one of the main carry through bulkheads. This is done on a sample of the fleet. By making use of the information stored in a large centralized data base system, 'individual airplane tracking' is done. Six times per year, the fatigue damage experience of the fleet is reported to the air staff, expressed in the so called 'crack severity index.' From the measurements it is known that the RNLAF is operating its F-16 fleet in a very damaging way. For this reason, it was decided to investigate the possibilities of how to decrease the severity of flying. In this program much attention has been given to the 'stress per G' relation during a flight. In particular the influence of flying with favorite take off store configurations has been studied.

The new generation of combat aircraft incorporate significant advances in maneuver capability, especially in such areas as post-stall control and sustained supersonic maneuver. These technologies expand the operational capabilities, and are essential for survival in a sophisticated threat scenario, and also to obtain favorable exchange ratios against an opponent using the current generation of fighters. The aim of this symposium was to review the various technologies, which combine to give this increased operational capability, and the techniques which are available or being developed, to overcome the design problems associated with the attainment of these goals. The symposium was divided into six sessions covering propulsion and integrated flight control, aerodynamics and control at high angles of attack, post-stall flight and control, flying qualities applied criteria, agility and simulation. For individual titles, see N94-34606 through N94-34631.

The simulation of highly agile aircraft during the development phase presents a significant challenge to aerodynamic and propulsion ground test and evaluation methodologies. The primary simulation challenges are caused by the inherent unsteady, separated nature of the flow phenomena associated with maneuvering aircraft that cause dynamic effects on the airframe and engine. In general, ground test techniques are quasi-steady and transient effects are represented by linearized superposition of steady-state data and unsteady small disturbances. Current trends in the design of tactical fighter aircraft require close coupling between the airframe, avionics, and propulsion systems. In addition, the extreme attitudes and high angular rate motions of this new breed of vehicle causes a strong nonlinear coupling between components. In the current paper, several aerodynamic and propulsion ground test and evaluation methodologies applicable to maneuvering aircraft are summarized, challenges associated with current techniques are identified, and an emerging integrated test and evaluation concept that can significantly impact the quality, time, and cost of developing a new flight vehicle is introduced. In the mid 1980s design work began on the U.S. Air Force's next generation air superiority fighter. The F-22 team, consisting of Lockheed, Boeing, and General Dynamics, embraced a design philosophy in which low observable technology, maneuverability, and supersonic performance were given equal consideration. Even with low observable features and long range weapon employment capabilities, the team believed that the probabilities of brief, short range air combat engagements, based on historical precedents and postulated future scenarios, demanded a highly agile design. Thrust vectoring emerged as a key feature for obtaining the desired agility without adversely impacting the aircraft's low observable signature. Thrust vectoring technology was incorporated and flown in the YF-22 Advanced Tactical Fighter prototype to investigate and validate the concept for the production F-22. The airframe, flight control system, and propulsion system were fully integrated. Thrust vectoring commands were generated by the aircraft's flight control computers and sent to each engine controller. Each engine controller independently performed the computations and issued the commands necessary to position the nozzle actuators to the correct vector angle while maintaining commanded thrust levels and engine stall margin. Flight tests showed that thrust vectoring provided major improvements in low speed maneuverability, enhanced handling qualities during tracking, and increased supersonic sustained turn performance as compared to current front line fighters. The S/MTD program has generated flight test data to validate four specific technologies: 2-D thrust vectoring & reversing nozzle; integrated flight/propulsion control; advanced pilot/vehicle interface including autonomous landing guidance; and rough field/high sink rate landing gear. These technologies have been integrated into an F-15B to provide mission benefits across the complete flight envelope from on-board guidance to a bad weather short landing, through significantly enhanced maneuvering benefits to supersonic performance. These technologies are either transitioning on to other aircraft, or can be considered viable design options for future aircraft. Derived from text

ONERA-IMFL develops techniques for high AOA maneuvering aircraft behavior studies. Specific wind-tunnels test coning and oscillatory coning motions, and constant pitch rate tests provide information about steady and unsteady, low speed aerodynamics.

Specific software facilitates data analysis and aerodynamic modelling. Application of nonlinear dynamic systems analysis techniques allows stabilities calculations and performance evaluation. For some maneuvers, behavior predictions can be validated with model flight tests in vertical wind-tunnel or in laboratory. These techniques have been used for forebody yaw control studies. Sensitivity of strakes efficiency to aircraft dynamic motions was measured in wind-tunnel facilities. Model flight tests confirm expected behaviors. Author (revised)

The main peculiarities of aerodynamic design of highly maneuverable aircraft are examined. The possibilities of improving the aerodynamic characteristics of aircraft at high angles of attack by use of high-lift devices and powered-lift systems (boundary layer control, blowing over wing, engine thrust vectoring) are shown. The conditions of controllable maneuver at high post-stalled angles of attack (alpha is less than or equal to 90 degrees) are established. Results of experimental investigations on the influence of wing planform and locations of aircraft components (wing, empennage) on the longitudinal stability and controllability at high angles of attack are presented. A comparative analysis of aerodynamic and maneuver performance of aircraft of various configurations (conventional, three-surface, canard) is performed.

The X-31 is a research aircraft built to explore the tactical benefits of the enhanced fighter maneuverability that is possible through the use of thrust vectoring. This paper gives background information on the program and on the aircraft. The high angle of attack envelope expansion phase is covered. This section details aircraft modifications that were required. The tactical utility phase of testing, including simulation and flight testing, is discussed. Helmet mounted display and supersonic thrust vectoring tests planned for the near future are briefly discussed.

The European Fighter Aircraft (EFA) was designed as a highly augmented, basically unstable aircraft. Its Stability and Control System (FCS) is of a much higher complexity than that used in earlier aircraft, e.g., the Tornado. To ensure that safe operation and optimum performance are not degraded due to possible handling quality deficiencies, new methods had to be used for both the development and the assessment of the aircraft. This paper describes the specifications and the methods used in customer assessment prior to first flight. An overview of these methods is provided. Author (revised)

This paper presents an analysis of current departure resistance and high angle of attack (HAOA) flying quality parameters with respect to applicability and utility in the design and assessment of today's enhanced maneuverability aircraft. Modern fighter/attack aircraft possess extremely nonlinear aerodynamic databases and highly complex flight control systems. In addition, these aircraft require both departure resistance and mission effective HAOA maneuvering capability. The limitations of using traditional departure susceptibility parameters such as C(sub n(beta (sub DYN))) and LCDP to address departure resistance and agility design and analysis issues are analyzed and presented herein. Discussion includes the design philosophy and tradeoffs of improving static versus dynamic departure resistance. In addition, the utility of open or closed-loop departure parameters derived from linear and/or decoupled equations of motion representing highly nonlinear aircraft is addressed. Finally, a general methodology outlining the application and validity of current departure susceptibility parameters to the modern aircraft HAOA flight regime is provided with recommendations. An initial set of aircraft maneuvers has been defined to augment the evaluation methods currently used by the flying qualities and flight test communities. These maneuvers are meant to employ the full range of available aircraft dynamics and to be applied over the full aircraft flight envelope. They include several closed-loop tasks and are the start of a set of demonstration maneuvers (of the type now used in the rotorcraft flying quality specification) for aircraft requirements. A primary goal was to establish a tie between design parameters, aircraft attributes, and the operational usage environment while maintaining control of the evaluation process. The approach was to concentrate on aircraft dynamics which occur in daily operations and to create pilot tasks which use those conditions to relate to important aircraft characteristics. Existing evaluation methods concentrate on comparing quantitative data to charts in MIL-Standards which predict flying qualities. The maneuvers discussed here directly measure the ability of the pilot to perform the tasks of interest and at the same time maintain a tie to the design community.

Three piloted simulation studies were performed by the U.S. Army Aeroflightdynamics Directorate to examine the influence of maneuverability and agility on helicopter handling qualities and to provide an expanded basis for the dynamic response requirements in Aeronautical Design Standard 33C, Handling Qualities Requirements for Military Rotorcraft. The experiments focused on aggressive tasks such as air-to-air combat and target acquisition and tracking. The first experiment focused on yaw agility requirements in the form of attitude quickness and bandwidth. The second experiment focused on pitch and roll agility and maneuverability requirements in the form of bandwidth, angular rate, and attitude quickness. The third experiment focused on maneuverability requirements in the form of normal and longitudinal load factor envelope for both conventional and compound

helicopters. Findings from the three studies are presented in the form of Cooper-Harper handling qualities ratings, pilot commentary, and task performance. Author

The environment in which a fighter pilot is required to operate is subject to continual change. This change arises from advances in technology and the altering world political situation. The only prediction that can be made with any confidence is that this change process is bound to continue with an unpredictable rate. In dealing with change, it is easy to prescribe a process but extremely difficult to implement the process with success. Success requires anticipation, reaction, reevaluation and modification of tactics and processes. The need for change must be recognized and accommodated. Such an approach, whether applied to fighter airplanes or any field of human endeavor, translates to agility. In undertaking this work, the group encountered many definitions of agility, some of which represented widely differing viewpoints. Often, in the past, protagonists of the varying ideas have fallen into heated arguments as to who is right. Fortunately, within the group, we have been able to stand back and examine the arguments with a dispassionate approach which has enabled us to understand the various arguments and see the common ground, rather than the differences. From our deliberations and discussions, the answer has emerged that no one was wrong, that all were right, at least in part. However, few had taken the time to stand back and take an all embracing view. Had they done so, then the message that all were trying to put forward might have had a wider and more sympathetic audience. All of the agility concepts that have been put forward have some merit. What was required was a way to relate the ideas and be able to apply them in a manner that is both reasonable and logical from both the viewpoints of the designer/supplier of aircraft and the customer/user of the vehicles that result. In defining a weapon system, it is essential to examine the component parts and their interaction, whether this be airframe, propulsion system, sensors, cockpit and avionics, or the weapons themselves and establish balance and synergistic integration between all of the components appropriate to the intended role and missions of the aircraft. It is the need to achieve balance and integration that is the prime driver for understanding operational agility as a set of concepts, supported by metrics which fit into a generalized framework, capable of evaluating a complex combat aircraft design with a view to maximizing the effectiveness of that design within affordable cost limits. The activities of the group have produced such a framework, derived from the various flight mechanics based concepts, but which would appear to be generalizable to cover the other systems, either as individual systems, or as a total weapon system. There is further work required to confirm that this framework will stand, but our initial investigations are very promising. This points the way forward for future aircraft. Achievement of this design balance requires all of the weapon system attributes to be studied, evaluated, and weighed against each other, together with the cost implications, to determine the optimum solutions. This may imply significant compromises if the roles and perceived threats are too diverse. A consequence is that future design specifications and requirements will need to be prepared in a different way from that traditionally used.

Relating to the activities performed by WG 19 a common area of interest was individuated by Aermacchi, Alenia, and the Flight Test Center of the Italian Air Force to investigate the application of the agility concept to conventional aircraft. Agility metrics and maneuvers have been developed to evaluate the operational effectiveness of a modern fighter in the new combat scenarios that evolved following the introduction of advanced technologies. Agility metrics and maneuvers, however, may be effectively adopted to evaluate also operational effectiveness of a conventional aircraft since those metrics have been developed to reproduce synthetically the new operational scenarios. The AM-X ground attack aircraft was hence chosen as a testbed to verify the applicability of the agility concept to conventional aircraft and to assess the possible benefits for operational training. The research activity is being carried out by simulator and flight tests to compare simulator cueing effectiveness against the real A/C and to investigate simulator effectiveness for agility training. Single axis agility maneuvers performed by simulator will be validated through upcoming flight tests. Results from this activity will be used to plan and perform further simulation test with complex multiaxis closed loop agility tasks. This activity proved that agility metrics and maneuvers are applicable also to conventional A/C as well, and are effective in evaluating it within a highly dynamic combat environment. Operational agility may be improved with adequate pilot training and simulator may be used as an effective tool for it. Anyway, particular attention must be paid to the definition of the training program to overcome shortcomings of the simulator cueing system. Author (revised)

Flying qualities standards are formally set to ensure safe flight and therefore to reflect minimum, rather than optimum, requirements. Agility is a flying quality but relates to operations at high, if not maximum, performance. While the quality metrics and test procedures for flying, as covered for example in MIL-STD-1797 or ADS33, may provide an adequate structure to encompass agility, they do not currently address flight at high performance. A current concern in both the fixed and rotary wing communities is the absence of substantiated agility criteria and the possible conflicts between flying qualities and high performance, i.e., more may not always be better. This paper addresses these concerns and suggests an agility factor that quantifies performance margins in flying qualities terms. The attitude quickness, from the latest rotary-wing handling requirements, provides an ideal agility measure and links handling with agility. A new parameter, based on maneuver acceleration, is introduced as a potential candidate for defining upper limits to flying qualities. These concepts are introduced within a framework aimed at unifying flying qualities and performance requirements. Finally, a probabilistic analysis of pilot handling qualities ratings is presented that suggests a powerful relationship between inherent airframe flying qualities and operational agility. (AGARD-CP-548) Copyright Avail: CASI HC A03/MF A03

This paper summarizes how an agility metric organizational structure was developed by the Flight Mechanics Panel Working Group 19. The structure was developed from existing concepts and was generalized for application to both fixed and rotary wing aircraft. The approach was based on time domain analysis concepts focusing on the 'time to complete' a specific operational task as the primary metric. From this metric a hierarchy of smaller time scale metrics were developed to emphasize the desired transient response dependent on the mission. The metric structure was developed for organizing the concepts of airframe agility as these were the most mature. The metric scheme is comprised of transient, experimental, and operational metrics. The transient metrics were defined as those time dependent parameters that characterize instantaneous airframe state changes. Experimental metrics were defined by discrete small task elements with compound properties that were optimized for evaluation purposes but were not necessarily recognizable as a mission related maneuver. Operational metrics were defined as complete mission task elements including the total vehicle response in multiple degrees

of freedom. The structure was also found to be applicable to other aspects of agility through the evolving concept of operational agility. This entailed the limited study of possible systems, pilot/vehicle interface, and weapon system time based agility metrics. Finally, the working group identified areas which required further study. RECENT ADVANCES IN LONG RANGE AND LONG ENDURANCE OPERATION OF AIRCRAFT [LES PROGRES RECENTS DANS LE DOMAINE DES OPERATIONS AERIENNES A LONGUE DISTANCE ET DE LONGUE DUREE]
Nov. 1993 317 p In ENGLISH and FRENCH Symposium held in The Hague, Netherlands, 24-27 May 1993

Over the past few years, the use of aircraft in long range and/or long endurance operations has proved to be a successful use of military resources. Technologies which improve the range and endurance of aircraft have seen considerable advances over the past ten years. Aircraft design for these features has matured considerably while the procedure of air-to-air refuelling has made global deployment and 24+ hour operations a reality. This Symposium attempted to summarize the latest technological advances in the various fields which in a combined manner define the range and endurance of airborne vehicles, i.e.: airframe design technologies, including aerodynamic structures; propulsion technology; the human factors problems associated with these types of missions; and air-to-air refuelling technologies and procedures. For individual titles, see N94-36322 through N94-36347.

This paper presents the results of structural optimization studies made on a High Altitude Long Endurance (HALE) aircraft at Wright Research and Development Center (now Wright Laboratory) during the late eighties. The purpose of this study is to investigate the feasibility of developing an ultralightweight airframe that can operate at high altitudes for extended periods of time in order to provide continuous reconnaissance, surveillance, communications and targeting functions. A variety of structural concepts and material studies were made prior to settling on a twin boom very high aspect ratio wing airframe. The wing and fuselage structures are made of truss substructures covered with skins, both made of high strength, high modulus, lightweight composite materials. Extensive structural optimization studies were conducted in order to obtain a lightweight structure. The large size of the aircraft drove the design to a stiffness critical structure. Author

This paper presents the conceptual work performed in Alenia during the recent years for defining some possible configurations for military and civil HALE (High Altitude Long Endurance) aircraft capable of carrying very different kinds of payloads and with mission durations ranging from one to two days. Also in relation to the aircrew fatigue implied by such a long flight time, they all have been conceived as UMA (UnManned Aircraft), achieving in that way a significant reduction of mass and complexity, withstanding the maturity of automatic control system. The aeromechanical aspect of the configurations (i.e aerodynamics, propulsion, structures, systems, weights and performances) will be discussed in detail considering that HALE-UMA type of aircraft have to face some technical challenges in many fields generated by the rather demanding requirements in terms of payload and endurance. Long haul traffic is a key sector that is constantly increasing. Since Concorde entry into service in 1976, it has tripled and will again double by the end of the century. There is no doubt that this long haul traffic development will create an increasing interest in high speed. The entry into service of a HSCT will enable flight time to be divided at least by 2 on these long routes, and could capture 20 percent to 40 percent of the long range market. To face up this future air transport landscape Aerospatiale, who jointly with British Aerospace has accumulated an unique experience in high speed transport with the Concorde program, is studying a potential successor: the Alliance project cruising at Mach 2. Due to the significant progress in technology already achieved or foreseen in the near future, the entry into service of a second generation supersonic transport can be envisaged as early as 2005. The success of this project is strongly linked to the capability of the aircraft and the engine manufacturers to provide the appropriate technology level to make the airplane environmentally acceptable and economically attractive. A significant effort in R & D is necessary to make available the challenging technologies: new materials, aerodynamics, propulsion.... Considering the level of investment required and the complexity of the problems to be solved, a close collaboration involving industrial partners is necessary on a world wide basis. This collaboration has already started. Following a long experience of bilateral cooperation, Aerospatiale and British Aerospace joined again in 1990 to study together a second generation supersonic aircraft around their respective concepts (AST and Alliance). Both partners are also cooperating with DASA, Boeing, McDonnell Douglas, the Japanese Industries, Alenia and Tupolev within an International Study Group. Author

THE CASE FOR SURFACE EFFECT RESEARCH, PLATFORM APPLICATIONS AND TECHNOLOGY DEVELOPMENT OPPORTUNITIES
J. M. L. REEVES *In* AGARD, Recent Advances in Long Range and Long Endurance Operation of Aircraft 10 p (SEE N94-36321 11-05) Nov. 1993
(AGARD-CP-547) Copyright Avail: CASI HC A02/MF A03

This paper commences by defining the conventional understanding of Surface Effect phenomenon and compares theories which show small reductions in drag occur above one span height above the surface. A discussion on reports of pilots who have flown their aircraft in surface effect ensues. From this, a broader understanding of surface effect is developed supported by low speed wind tunnel tests and Russian published technical documentation. The author divides surface effect platforms or, perhaps, better described as Enhanced Performance Low Flying Platforms (EPLFP's) into three distinct categories. Potential applications of surface effect platforms are discussed based on the changing world, the evolving airline industry and airport constraints. Missions and specific mission examples are given. Reasons for the pursuit of rather large platforms are presented as are some of the major technical hurdles which will have to be overcome for them to succeed. Technology opportunities are discussed. A summary concludes the paper. Author

Both commercial and military aspects of Cargo Transport Aviation were discussed at the International Symposium organized by the French Aerospace Academy, held in March 1993 in Strasbourg. This paper summarizes some of the contributions and discussions dealing with the future role of the Air Cargo Transportation in relation to a global international policy of military and humanitarian intervention, including their technical and operational aspects. In a first part, the status of the World's Air Cargo activity is reviewed in terms of the main operational cargo airplanes, their capacity and their range, used both for commercial and military purposes; it includes the family of large cargos developed by Antonov in Ukraine and preliminary designs of huge cargo projects by the Russian laboratory TsAGI for 250 to 500 tons payload, and by NASA with spanloader or conventional schemes for intermodal containers transport. In a second part, the present U.S. Military Airlift forces are analyzed, with some comments on their recent global airlift deployment during the Gulf War. It is concluded that, as regards long term global policy, such existing task forces are totally inadequate to either stop immediately some local conflicts around the world, or to save population, in case of major natural or man-made disasters. That is why a much larger airlift system should be developed on an intergovernmental basis, the main objective would be its 'strategic efficiency' instead of a 'profit earning capacity', as used in commercial aviation. For that purpose, a 'supercargo' can be defined, developed and produced in the framework of an international consensus between the major aeronautical powers. Its size, configuration, operational characteristics and performance must be discussed, and a compromise agreed to cope with the main military and humanitarian missions; but such 'supercargo' airplane would be certainly much larger than the present ones, with two to four times their payload, and a transcontinental range capability; for their development, advantage would be taken of the best technologies that would become available in the next decade, and of the availability of design capability in the world's aircraft industry resulting from the present crisis. A flying wing configuration is suggested as a basis for a preliminary project. Finally, there is certainly a commercial spin-off of such massive supercargo production, if used to compete successfully with the surface transportation systems of large intermodal containers already used on major international markets. The present high performance aircraft designs are increasingly using high strength composite structures, mainly made of unidirectional carbon fiber tapes. But the composite technology is still afflicted with several weak points, e.g. the lack of adequate mechanized tape application techniques for complex compound structures, unsatisfying designs and design methods and missing continuous CAD/CAM-linkage. In this paper we will describe an 'Integrated Tape Laying System' (ITLS) which uses a new tape steering technology for automated manufacturing of complex parts. This system integrates the steering technology's potentials and restrictions completely in the design process to avoid time consuming iteration loops and to optimize the structure. To be able to understand the detailed process a short overview about two different geometry models demonstrated on a typical example will be given. From this the optimal detailed process will be derived, with an important influence from the specific manufacturing technology. Finally some remarks on economic potentials are outlined with their impact on typical composite aircraft parts related to different automated manufacturing techniques. Author (revised)

The EH101 is a new medium helicopter being produced by EH Industries, a company jointly owned by Agusta of Italy and Westland of the UK. The aim of this presentation is to explore the roles in which the EH101 will be called upon to cover long ranges and examine its suitability for these roles. The roles which will be examined fall into the following categories: search and rescue, self-ferry, and special operations. The successful completion of such missions will demand particular capabilities of the crew and the machine. The following aspects of aircraft design will be looked at with respect to the EH101: in-flight refuelling, all-weather capability, maintenance requirements, and crew environment. Because of the wide ranging nature of the subject and the limited time available this is intended to examine only the key points required for these roles and capabilities. Author (revised)

Until the last few years, the idea of a convertible aircraft did not progress into testing because the available technology did not satisfy the cost/efficiency parameters, and because the need for such an aircraft was not felt. Today, conditions are different. Strategic necessities and technical progress have created an atmosphere in the United States and in Europe where this old dream of engineers may be resurrected. Within the research program on AIRBUS, the Aerodynamics Conception Department of Aerospacial Avions is responsible for the research on the aerodynamics of the reactor's pylon, air inlet (or technical evaluation on the system provided by the constructor) and for the optimization of aerodynamics in the ensemble of the engine installation. This includes studies on minimizing undesirable effects (loss of carrying capacity, increase in drag) due to the interaction between wings, pylon, and engine pod. This article lists the various tools used by the above department in order to fulfill its task: the C.A.O. system, principally conceived for aerodynamics concerns, the surface and volume representation systems as well as the main systems of 3D calculations on complex geometric arrangements. Three recent applications of these methods are presented within the framework of the development of the AIRBUS A330/A340 aircraft, and associated systems: air flow in the zone of pylon/wing intersection; effects due to the size of the engine in comparison to given wing characteristics and modelization of the jet's effect; and orientation of relationship between engine thrust and aircraft. The Aerospace Engineering Test Establishment (AETE), as the Canadian Forces (CF) flight test authority, has recently completed flight tests and analysis of a major store certification program to establish an operational flight envelope for the carriage and jettison of a newly designed 480 gallon external fuel tank (EFT) for the CF-18 aircraft. The certification process involved a progressive series of analysis, wind tunnel tests, qualification tests, ground tests, and flight test activities. Most of the preflight activities were performed by the designer, McDonnell Aircraft Company (McAir), while all flight testing was the responsibility of AETE with engineering support from McAir. The progression of events from the qualification testing to the final flight testing recommendations are summarized herein. The primary focus of this paper is on the flying activities such as flutter, loads, stability and control, separation/jettison, and performance. Special instrumentation, flight test techniques, and test concept philosophy are also discussed. This paper highlights various technical problems encountered, such as the near flutter onset condition observed with tanks 50 percent full, the premature failure of the inboard wing spar pylon receptacle discovered after the last maneuvering loads flight, and the localized pitchup phenomena observed during stability and control (S&C) testing. A glance at the increased range and payload capabilities is also included. Overall, the 480 gallon EFT was determined to be a viable option for the CF-18 aircraft. Author

The Rafale is the latest combat aircraft built by Dassault Aviation. It is equipped with an in-flight refueling system using a fixed pole. This article relates the important steps taken during its conception and the various technologies that were used: structure, aerodynamics, systems, etc. The second part of the article describes the testing that was conducted in-flight as well as on the ground, making it possible to corroborate the performance of the systems and the flight characteristics of this aircraft.

Starting seven years ago, the USAF Aeronautical Systems Center began analyzing future tanker system requirements and developing plans for satisfying these requirements. Frontier Technology, Inc. (FTI) supported the USAF in four of the efforts. Frontier has completed one KC-135 multipoint analysis and is currently doing a second one. The completed effort determined: the pros and cons of hose-drogue refueling and the best fuel pumping rate for the KC-135 using two wing air refueling pods. The current job involves a more in-depth, overall assessment of operational needs, concepts of operation, and alternative wing pods. It emphasizes compatibility with Allied and U.S. Navy aircraft receivers. Frontier Technology is presenting two related papers at this AGARD symposium. This paper covers the rationale and requirements for multipoint refueling. It covers trends and future employment of aerial refueling tankers, as well as the increasing importance of interoperability. Derived from text

Over the past decade, there has been increased emphasis on interservice and international operability with respect to aerial refueling (AR). One area concerning interoperability that needs to be considered in light of the increased trend towards large multipoint tankers is receiver flying qualities during AR. This paper stresses the importance of conducting receiver proximity trials to optimize refueling position behind the tanker and providing the pilot with the best receiver flying qualities for AR that can be attained. Receiver flying qualities behind the tanker can be seriously degraded if proper steps to optimize receiver refueling positions are not taken prior to final design. Poor receiver flying qualities in the refueling positions can reduce engagement success rate, increase the amount of training required, increase mishaps, increase refueling cycle time and seriously degrade mission effectiveness of the tanker. There are, of course, many other considerations regarding tanker/receiver compatibility such as airspeed/altitude compatibility, fuel system compatibility, communications, night lighting, etc. But this paper primarily addresses receiver flying qualities and the importance of refueling position behind the tanker as it pertains to flying qualities. Specific programs discussed are Navy trials with the Air Force KC-10 and KC-135 tankers and Navy programs to bring a wing pod tanker capability to the P-3 airplane. Additionally, efforts underway to enhance tanker mission effectiveness of the KC-130 with a variable geometry drogue are discussed and their ramifications explored.

This paper presents a process that leads from comprehensive tanker system requirements analysis to the development of a technology 'road map.' This road map is a matrix listing key technology requirements for future air refueling tanker aircraft capabilities and the current status of research and development activities in these key areas. Generalized examples from material prepared under a U.S. Air Force Contracted Research and Development (CRAD) study are utilized. Multimission capabilities (i.e., tanker, and cargo and passenger transport) are often preferred for these new aircraft. This allows the flexibility of use for many purposes besides that of just air refueling: military cargo and passenger deployments, humanitarian relief, medical air evacuation, executive transport, etc. For this reason these tankers are often referred to as 'tanker/transports' to emphasize these capabilities. In this paper, the term 'tanker' is used to describe what in all likelihood will be a tanker/transport. Author (revised)

The basis of this paper is analyses performed by Frontier Technology, Inc. for the USAF. Frontier has performed evaluations of multiple tanker candidates to supplement and to eventually replace the KC-135 tanker fleet. The analyses included tanker refueling support for six mission areas: theater employment of combat fighter aircraft, intercontinental fighter deployments, extended offshore range of naval carrier operations, intercontinental airlift, North American air defense, and long range nuclear warfare. The characteristic airborne refueling needs of the six missions are somewhat different. The first mission listed, theater employment of combat fighter aircraft, is characteristically different from the

other areas in that it stresses the need to refuel more aircraft over shorter periods of time than the other five mission demands except for some situations in air defense support. In theater employment operations the demands of the larger tanker aircraft are stressed the most when waves of aircraft attack during short periods of time in the attempt to overwhelm enemy defenses. This tanker demand is in contrast to that of the nuclear warfare mission which requires large amounts of fuel for a single receiver (bomber) aircraft on a lengthy mission where the precise refueling time is not critical. Replacement of the RNLAF F-27 transport fleet, first mooted in 1984, became a serious option a few years later because of a growing need for AAR capacity. Years of discussion and market research resulted in a requirement for (among others) two DC-10 aircraft to be modified into tanker/transport aircraft. The budget was not sufficient to develop new KMD-11 tanker aircraft, nor did it allow buying existing tanker aircraft. On the basis of earlier programs from other countries, involving different aircraft, RNLAF decided that it should be possible to modify two DC-10 aircraft into so-called KDC-10 aircraft. With assistance from McDonnell Douglas Aircraft (MDA), four aircraft were selected on the basis of a number of criteria. These aircraft were studied thoroughly. On the basis of condition and price two Martinair DC10-30 CF aircraft were purchased on 30 June 1992. These will be modified into KDC-10 tanker/transport aircraft. The RNLAF contracted MDA to study feasibility, timetable, and cost of modifying two (Martinair) DC-10-30 CF aircraft into tanker/transport aircraft. The study concluded that the program was feasible within the proposed time frame, given that USAF would cooperate. Also the total cost estimate could be kept within budget. It was not possible to keep the KC-10 Aerial Refuelling Operator (ARO) station, so a new Remote Aerial Refuelling Operator (RARO) station will have to be developed. The design, however, is not completely new as it has been implemented on other aircraft. The RNLAF expects the first KDC-10 aircraft to be in service by January 1995, the second to follow approximately three months later. Based on this, the modification of the first aircraft is scheduled to start on 1 July 1994 and the second in December 1994. Development of the modification program has already begun. USAF has been requested to assist RNLAF in program management, contracting, and purchasing of certain parts. Author

This paper describes the development flight test program for the CC-130H(T) Tactical Aerial Refuelling Tanker. The Canadian operational requirement is first described, followed by a detailed discussion of the test item, receiver aircraft, and the ground/flight test method and preliminary results. The development is significant since it represents the first certification of the Flight Refuelling Limited Mk 32B refuelling pods on a Hercules aircraft. Further flight testing to be conducted in the near future are also mentioned. Author

Drones are of great importance for reconnaissance and surveillance in military applications. In regard to maritime drones Dornier demonstrated the automatic landing of a drone on a moving ship motion simulator in December 1991. The landing accuracy is determined by the tracking process. The tracking is performed by a laser tracker, which measures the drone position relative to the ship. Not only the drone but also the ship is equipped with an INS (Inertial Navigation System). The landing computations are performed in earth-fixed coordinates, whereby the earth-fixed positions are delivered by the INS. The determination of the drone position results from a combination of measurement values from the airborne INS and data from the ship laser tracker. The combination of the different information in the drone is performed in a Kalman-filter. The concept was verified in an experimental program. During the experimental program 13 flights were performed. The tracking accuracy was approximately 0.2 m.

This AGARDograph is a sequel to the previous AGARDographs published in the AGARD Flight Test Techniques Series, Volume 2 on 'Identification of Dynamic Systems' and Volume 3 on 'Identification of Dynamic Systems - Applications to Aircraft - Part 1: The Output Error Approach' both written by R.E. Maine and K.W. Iliff. The intention of the present document is to cover some of those areas which were either absent or only briefly mentioned in those volumes. These areas are Flight Path Reconstruction, Nonlinear Model Identification, Optimal Input Design and Flight Test Instrumentation. The present approach to identification is rather different from that presented in the earlier AGARDographs in the sense that the identification problem is decomposed into a state estimation and a parameter identification part. This approach is referred to as the Two-Step Method (TSM), although one will find other names like Estimation Before Modelling (EBM) in the literature. It will be shown in the present AGARDograph that this approach has significant practical advantages over methods which no attempt is made to decompose the joint parameter-state estimation problem. The two-step method is generally applicable to flight vehicles such as fixed wing aircraft and rotorcraft which are equipped with state of the art inertial reference systems. The theoretical developments in the present AGARDograph will be illustrated with examples of a flight test program with the De Havilland DHC-2 Beaver aircraft, the experimental aircraft of the Delft University of Technology which has been used for almost two decades to test new ideas in the science of aircraft parameter identification. The course addresses the ingredients of new algorithms for accurate and cost effective numerical solutions of design problems. A special emphasis is given to the following topics: fundamental mathematical properties of methodologies for solving optimization problems using control theory and variational formulations; numerical aspects of fast algorithms coupling constrained optimizers and flow analysis solvers and their implementation; geometric representations and choice of design variables; and real life 3-D applications encountered in Aerospace Engineering in order to demonstrate the usefulness of these design methodologies to practical design problems. For individual titles, see N95-16563 through N95-16573.

These lectures describe the implementation of optimization techniques based on control theory for airfoil and wing design. In previous studies it was shown that control theory could be used to devise an effective optimization procedure for two-dimensional profiles in which the shape is determined by a conformal transformation from a unit circle, and the control is the mapping function. Recently the method has been implemented in an alternative formulation which does not depend on conformal mapping, so that it can more easily be extended to treat general configurations. The method has also been extended to treat the Euler equations, and results are presented for both two and three dimensional cases, including the optimization of a swept wing.

The present paper discusses the problem of inverse shape design, where the geometry of a wing should be determined such that it will have a prescribed surface pressure distribution at the design condition considered. A survey is given of so-called decoupled-solution methods or this problem. With this type of methods the flow field around a current estimate of the wing and a subsequent new estimate of the wing are determined by two separate computational steps in an iterative process. A global description is given of the main features of the underlying theories and some examples of application are given. A detailed description is given of the NLR method for inverse shape design based on the residual-correction approach.

An efficient numerical approach for the design of optimal aerodynamic shapes is presented in this paper. The objective of any optimization problem is to find the optimum of a cost function subject to a certain state equation (Governing equation of the flow field) and certain side constraints. As in classical optimal control methods, the present approach introduces a costate variable (Language multiplier) to evaluate the gradient of the cost function. High efficiency in reaching the optimum solution is achieved by using a multigrid technique and updating the shape in a hierarchical manner such that smooth (low-frequency) changes are done separately from high-frequency changes. Thus, the design variables are changed on a grid where their changes produce nonsmooth (high-frequency) perturbations that can be damped efficiently by the multigrid. The cost of solving the optimization problem is approximately two to three times the cost of the equivalent analysis problem.

This paper is an introduction to applied optimization of engineering problems, with an emphasis on aircraft design. First, the optimization problem is described-namely, the objective function and the problems often involved in its optimization, the variables or parameters over which the objective function is optimized, and the constraints upon the objective function. Formulation of the optimization problem to ensure rapid and accurate convergence is discussed and illustrated with specific examples. Three classes of optimization methods: evolution, downhill simplex and gradient optimization, are discussed. The robustness and speed of these optimization methods are evaluated and compared. Finally, a number of practical implementation issues related to optimization are highlighted.

This work describes the methodology used to compare supersonic design concepts and its use in industry. The design concepts are analyzed with a modular synthesis model and compared on the basis of operating economy with specified performance and environmental impact. The analysis routines of the synthesis model are mainly configuration independent and represent fixed levels of structural, aerodynamic and propulsion technology. The specialist departments are responsible for the content of the routines, and later verify the design with more refined methods. At present more than two hundred variables describe the aircraft geometry, engine characteristics and mission.

More than twenty of those variables representing the aircraft and its flight-profile are optimized simultaneously as a function of Mach number, payload and range. Because the various designs are analyzed with the same routines and optimization procedures they can be easily compared. This aircraft pre-optimization results in a significant reduction of the number of follow-on detail-design cycles, especially for non-conventional designs. Author

This paper will discuss examples of aerodynamic shape optimization at Deutsche Airbus in Bremen. First, we will introduce a general approach to aerodynamic shape design based on minimization of aircraft life energy costs. Realistic constraints are introduced on lift, pitching moments and thickness. This method is applied to the quasi-3D design of multipoint transonic wings which are analyzed by a full potential code with a coupled boundary layer calculation. Finally, this method is applied to the wing-body design of a Supersonic Civil Transport that is analyzed with a linear potential code with real flow corrections and a decoupled boundary layer calculations. Despite progress toward automated shape design in Industry has been penalized until now by excessive computing costs, useful innovative design methodologies have been recently proposed for computing different academic and industrial designs of nozzles, airfoils and wing-body combinations operating in inviscid flows modelled by the potential and Euler equations. Since the designer has a precise idea of the pressure distribution that will produce the desired performance, not only optimization problems but also inverse problems have to be considered in current design. The goal of this lecture is to describe the major ingredients of new algorithms developed by european partners of the AERO 89-0026 project, which allow accurate and cost effective numerical solutions of optimization problems and also to illustrate the capabilities of design software on test cases proposed in a Workshop for validation purpose. Industrial applications illustrating these methodologies are also presented. Finally a new emergent search method for non linear optimization problems provided by simple Genetic Algorithms (GA's) is briefly described and illustrated by a few examples related to inverse problems and applied to reduction of viscous drag. This paper deals with the problem of calculating loads on engines and their supporting structures when inertial characteristic, high engine speeds, large displacements, imposed by extreme atmospheric disturbances, give an important impact of gyroscopic effect. A direct method integrating the gyroscopic action in Lagrange's equations as a function of the polar moment of inertia, engine revolution speed and precession speed is presented and compared to the more common practice of superimposing gyroscopic effects on the basis of the angular speed calculated at the engine center of gravity. The results establish a good correlation between the two method on pitch and yaw moments on engine. On the other hand, transfer function modifications due to gyroscopic effects generate an increase of other loads for the direct method calculations, for both the turboprop and the turbojet aircraft. Effects of the aerodynamic force of the propeller due to the engine response are also examined. Author

A STUDY OF THE EFFECT OF STORE UNSTEADY AERODYNAMICS ON GUST AND TURBULENCE LOADS

M. OLIVER, J. CASALENGUA, C. MADERUELO, Y. CAMACHO, and H. CLIMENT *In* AGARD, Aircraft Loads due to Turbulence and their Impact on Design and Certification 12 p (SEE N95-18597 05-08) Dec. 1994

(AGARD-R-798) Copyright Avail: CASI HC A03/MF A01

Gust and turbulence loads are the most severe conditions for some parts of the aircraft, especially in the outboard wing region. The addition of external stores usually alleviates the gust/turbulence loads on the wing but becomes critical for other components as pylons and wing/pylon attachments. Safety implications and all-weather envelope of current fighters force an accurate study of the gust/turbulence response of the aircraft for each store configuration. Inertia is the most important contribution of the store to the gust/turbulence loads. Nevertheless, store unsteady aerodynamics should be included if significantly changes the results of the gust/turbulence response. This paper is devoted to the analytical study of the effect of store unsteady aerodynamics on gust/turbulence response. A large number of configurations have been included in the study. Several regulations to define the gust/turbulence excitation have been used. Author

COMPARISON OF STOCHASTIC AND DETERMINISTIC NONLINEAR GUST ANALYSIS METHODS TO MEET CONTINUOUS TURBULENCE CRITERIA

PATRICK J. GOGGIN *In* AGARD, Aircraft Loads due to Turbulence and their Impact on Design and Certification 12 p (SEE N95-18597 05-08) Dec. 1994

(AGARD-R-798) Copyright Avail: CASI HC A03/MF A01

Current continuous turbulence Power Spectral Density (PSD) gust analysis methods are valid only for linear aircraft. In the past, many methods for the analysis of nonlinear aircraft to meet the current PSD gust criteria have been proposed. In this paper, three stochastic simulation based and one deterministic function based methods are compared and evaluated for the compliance of nonlinear aircraft to the current continuous turbulence gust criteria. The aircraft configurations analyzed in this paper include a symmetric aircraft model coupled to a nonlinear gust load alleviation (GLA) system and an anti-symmetric aircraft model coupled to a nonlinear yaw damper system. Results from these four nonlinear methods are compared to linear closed and open-loop results as well as currently used linear approximation methods. Computing performance issues are addressed to provide the reader with a complete picture of the trade-off between the analysis' accuracy and computing cost. Author

DESIGN LIMIT LOADS BASED UPON STATISTICAL DISCRETE GUST METHODOLOGY
D. L. HULL *In* AGARD, Aircraft Loads due to Turbulence and their Impact on Design and Certification 8 p (SEE N95-18597 05-08) Dec. 1994
(AGARD-R-798) Copyright Avail: CASI HC A02/MF A01

Statistical Discrete Gust (SDG) methodology for extreme turbulence provides the basis of a design criterion that accounts for: (1) the statistical nature of design level turbulence; (2) the effects of lightly damped aircraft responses; (3) critical responses that may have significant frequency separation; and (4) the effects of nonlinear control systems. The criterion would eliminate the need for multiple design criteria and could increase the structural efficiency of new aircraft. The increased efficiency would be the result of having equally probable design limit loads for all gust critical components of the aircraft. Author

In the operation of airplanes, atmospheric turbulence creates a broad spectrum of problems. The nature of these problems is presented in this paper. Those that are common to both the commercial carriers and to the military fleet are discussed first. Attention is then focused on the problems that are of special concern in military operations. An aim is to bring out the need for continued effort in the gust research area. Author

Acoustic fatigue failure in aerospace structures has been a concern for many years. New prediction techniques are needed for the new materials and structural concepts of interest and higher sound pressure levels encountered. The objective of this program of work is to improve the fundamental understanding of the nonlinear behavior of beams and plates excited from low to high levels of excitation. Experiments have been conducted utilizing a clamped-clamped (C-C) beam statically tested and shaker driven at increasing levels of excitation. Similarly, C-C-C-C plates were excited by a vibration shaker and in a progressive wave tube. The total strains and the components, bending and axial, and the displacements were measured with increasing levels of excitation. Bistable behavior was observed with sinusoidal excitation for both the beams and plates. The measured axial or membrane strains were very low compared to the bending strains for high levels of excitation. The beams randomly excited exhibited a slight frequency shift and peak broadening, which can be attributed to an increased stiffening or hard spring nonlinearity. The plates randomly excited exhibited a greater frequency shift and peak broadening than the beams. The dynamic tests resulted in a nonlinear relationship between the response strains and displacements and the excitation levels. A multimodal model is discussed to estimate the mean square stress response due to high levels of excitation. Author

MODELLING STRUCTURALLY DAMAGING TWIN-JET SCREECH
MARY KAE LOCKWOOD, STEVEN H. WALKER, and ALAN B. CAIN (McDonnell-Douglas Corp., Saint Louis, MO.) *In* AGARD, Impact of Acoustic Loads on Aircraft Structures 8 p (SEE N95-19142 05-71) Sep. 1994
(AGARD-CP-549) Copyright Avail: CASI HC A02/MF A03

Closely spaced twin jet aircraft have been known to be susceptible to aft-end structural damage due to the high sound pressure levels resulting from twin jet screech. An initial engineering workstation tool to predict the occurence of screech, ultimately allowing the design of configurations which will not result in screech, is presented here. The model has been developed in a modular fashion to facilitate upgrades. The implementation takes advantage of a graphical interface, yielding predictions of screech amplitude versus frequency within a few seconds once the initial flowfield is defined. The four physically based modules in the code, for the instability waves, shock-vortex interaction, acoustic feedback and receptivity, are based on analytical, computational and experimental research. Preliminary results for 2-D jets illustrate the effects freestream Mach number and shear layer growth rate have on the screech amplitude and frequency. Author

Described here are the Integrated Control and Avionics for Air Superiority (ICAAS) piloted simulation evaluations, along with the system development leading up to the simulations and the data analysis plan for evaluating simulation results. The ICAAS advanced development program is sponsored by the United States Air Force Wright Laboratory at Wright Patterson Air Force Base, Ohio. A research and development contract was awarded to the McDonnell Aircraft Company, St. Louis, Missouri, in September 1987. The program objective is to develop, integrate and demonstrate critical technologies which will enable United States Air Force tactical fighter 'blue' aircraft to kill and survive when outnumbered as much as four to one by enemy 'red' aircraft during air combat engagements. Primary emphasis is placed on beyond visual range (BVR) combat with provisions for effective transition to close-in combat. An overview is given of the ICAAS system and its functions. The hardware elements needed to implement the ICAAS system are described and require high throughput parallel processing Reduced Instruction Set Computer (RISC) computers and an advanced 'glass' cockpit. The development of the ICAAS system is discussed as it moved from rapid prototyping to unit testing of attack management and flight Management software and finally into hardware software integration testing prior to manned simulation. The Data Analysis plan for reducing piloted simulation results to assess system performance is described. The evaluation of the ICAAS system performance encompasses not only integrated system performance but also performance of individual ICAAS subsystems as they are reflected by measures of situation awareness, flight management utilization, weapon utilization and sensor effectiveness. This includes use of multiple measures of performance as well as univariate and multivariate analyses to assess ICAAS system performance. Author

APPLICATIONS OF ASICS TO AVIONICS
Feb. 1992 49 p
(AGARD-AG-329; ISBN-92-835-0657-X) Copyright Avail: CASI HC A03/MF A01

An overview of how Application Specific Integrated Circuits (ASICs) can be a key factor in avionics systems is presented. The technical capabilities and possibilities of ASICs in avionics applications are discussed along with the essential characteristics and various types of ASICs that are available. The computer aided design (CAD) tools necessary for the rapid development of ASICs are discussed. Two specific examples of applications are cited: (1) the imbedded computers necessary for airborne radar digital signal processing; and (2) the ASIC role in image processing for aircraft cockpits. For individual titles, see N92-28377 through N92-28380.

The characterization of targets is of primary interest because it is needed for establishing the tactical situation, optimizing target acquisition, and optimizing armaments utilization. Due to the necessity of obtaining information on threats which have low signatures and are equipped with counter-measure systems, the operational specification of airborne systems have come to rely on the technologies providing multispectral analysis of targets. Specific topics discussed include aircraft fire control, air to air missiles, air to ground missiles, aerial warfare, multispectral detectors, integrated systems architectures and algorithms, and data fusion. For individual titles, see N92-32438 through N92-32450.

Discussed here are the requirements for increased sensor performance. It is suggested that one solution may be to provide a dual sensor capability. The difficulties of conducting tests under realistic conditions are set out, and the alternative of providing calculated performance based on recorded weather and target data is suggested. Based on modeling for two locations in the Gulf region, it is shown that TV can offer major advantages in hot humid conditions. Equipment providing a dual sensor capability is described and the results of carrying out trials flying in the United Kingdom are presented. Author

The German Air Force has decided to build a forward looking infrared (FLIR) system in order to derive and to consolidate the different technical requirements for their different technical tasks. This FLIR design was designed and built on the basis of available and proven technologies. The equipment is pod-mounted in order to avoid modification of existing Tornado aircraft. Two different modes of operation are comprised in one hardware. These are the navigation mode, used as a pilot aid for flying at night and in adverse weather, and the fire control mode, used for passive targeting and navigation-update. The mechanical and optical designs are presented as well as the electronics architecture. The performance of the sensor system is described. Author

The German antitank helicopter PAH 2 is presently under full scale development, together with the French antitank helicopter HAP, in a cooperative effort between France and Germany. The PAH 2 represents the current state of the art in target acquisition and fire control systems for helicopters in Europe. The targeting system consists mainly of a mast mounted platform housing several

sensors operating in different spectral ranges. It is used for the detection, recognition, and identification of targets at increased ranges as well as to aim and guide 2nd and 3rd generation antitank missiles. Further sensors and systems are available to support the crew target acquisition or detection of threats in the battlefield and to support coordination of several helicopters in a flight. Author

Described here is a system that includes integrated fire control algorithms, software, and related control and display concepts for air to air combat in the multiple target environment of the 1990's. This system, now completing advanced development, fuses data from multiple sensors and presents integrated fire control information to the pilot in a simplified manner for improved situation awareness and decreased workload. The resulting algorithms, software, and display concepts are described. The system was demonstrated and evaluated in a flight simulator with Air Force pilots. The fire control software, which was developed in the Ada language, was implemented in a distributed data processing complex using MIL-STD-1750A processors. The sensors and data links, as well as the aircraft and its environment, were simulated by mathematical models. Author

Due to well-known advantages such as low weight, reduced volume, low consumption, visibility (under high brightness) reliability, to mention the most important, the flat panels have already started to replace the CRT in the world of military aircraft. Among flat panels, the liquid crystal active matrix display is the most advanced. Full colors and grey shades displays are mass produced for commercial applications and new military cockpits, both for airplanes and helicopters based on that technology (Rafale is used as an example to illustrate the advantages of LCD compared to CRT). Furthermore, liquid crystal panel is a technical key which will help future cockpit concepts to wake-up to life. The head level display and the large interactive display are among them. Projection techniques and liquid crystal cells are merged to take benefits of liquid crystal, removing the drawbacks (that notion is illustrated by a brief description of a head level display demonstrator). DESIGN CONSIDERATIONS FOR A NIGHT, AIR-TO-SURFACE ATTACK CAPABILITY ON A DUAL ROLE FIGHTER
ROBERT A. HALE, JOHN J. CHINO, L. LARKIN NIEMYER, JOHN R. JADIK, and BARRY E. LIGHTNER *In* AGARD, Combat Automation for Airborne Weapon Systems: Man/Machine Interface Trends and Technologies 8 p (SEE N93-28850 11-54) Apr. 1993 Prepared in cooperation with Westinghouse Electric Corp., Orlando, FL
(AGARD-CP-520) Copyright Avail: CASI HC A02/MF A03

The Falcon Knight design objective was to achieve a compact lightweight and affordable night air-to-surface attack capability for a small single seat dual role fighter. The design constraints were cost, performance, physical size, weight, aerodynamic impact, and ease of retrofit. An analysis of the mission and the pilot's tasks and workload during the mission revealed the need for two electro-optical lines-of-sight (LOS's). The first LOS, pilot age, is required to provide an uninterrupted night vision, or pilot age, capability for a high level of situational awareness at all normal pilot viewing angles. The second LOS, targeting, is to provide a simultaneous independent targeting capability for cueing, search, detection, recognition, fire control tracking, and/or weapon hand-off leading to the delivery of weapons on the target. The Falcon Knight forward looking infrared (FLIR) sensor is a unique optically multiplexed dual line of sight (LOS) Head Steered FLIR (HSF) which provides both pilot age and targeting LOS's simultaneously within the design constraints cited above. The Falcon Knight FLIR is also integrated with the aircraft's Fire Control Radar (FCR) to create an integrated FLIR/Fire Control Radar Multisensor. Westinghouse built a company funded Falcon Knight FLIR/Fire Control Multisensor Radar prototype. The prototype was evaluated in flight on the Westinghouse BAC 1-11 Avionics Test Bed aircraft. The United States Air Force is currently evaluating the Falcon Knight FLIR/Fire Control Radar Multisensor on the Advanced Fighter Technology Integration (AFTI) F-16 test aircraft at Edwards Air Force Base (AFB) California. After showing how the complexity of digital systems is doubling about every five years, and evoking the difficulties caused by this evolution, a methodological approach is described called the 'Systems Development Workshop' aiming to gain mastery of this evolution. Among design, production and validation stages, the importance of the design process is emphasized. The most acute problems of system development are generally described, and examples are given of the power and benefits that can be expected from computer design tools. System architecture design and functional specification are expanded somewhat, to show what benefits can be expected from an integrated approach. Through the SAO example, all development stages are evoked. A rough outline of the necessary capacities for a common work environment is drawn. Finally, it is noted that the increasing necessity of

international cooperation in civil aviation consolidates the proposed approach. Author

A COMMON ADA RUN-TIME SYSTEM FOR AVIONICS SOFTWARE
CLIVE L. BENJAMIN, MARC J. PITARYS, ELIEZER N. SOLOMON, and STEVE SEDREL *In* AGARD, Aerospace Software Engineering for Advanced Systems Architectures 11 p (SEE N94-29315 08-61) Nov. 1993
(AGARD-CP-545) Copyright Avail: CASI HC A03/MF A03

The United States Air Force (USAF) requires the use of the Ada programming language in the development of new weapon system software. Each Ada compilation system uses a Run-Time System (RTS) for executive services such as tasking, memory management, and system initialization. Implementing and using custom RTS services in each software development activity inhibits avionics software reuse and portability. In addition, the USAF must support many Ada compilers over the operational life of the weapon system. Finally, extensive testing and knowledge is required for each RTS. In 1990 the USAF began defining a Common Ada Run-Time System (CARTS) for real-time avionics applications. A contract was awarded to Westinghouse Electric Corporation (WEC) with subcontracts issued to compiler vendors DDC-I, Inc. and Tartan, Inc. A specification for the CARTS was completed in 1991 and coding of selected CARTS features was undertaken. The specification defined common interfaces between the application software and the RTS, and between the Ada compiler and the RTS. Incremental coding of the CARTS prototype is being done by DDC-I for the MIPS R3000 processor, and by Tartan for the Intel 80960 MC processor. Several prototypes have been developed and tested. This paper covers the significant CARTS features and services offered to avionics software engineers. The paper provides the results of performance testing of the CARTS features. Finally, this paper provides information on the appropriate use of the CARTS by avionics software engineers.

ADA RUN TIME SYSTEM CERTIFICATION FOR AVIONICS APPLICATIONS
JACQUES BRYGIER and MARC RICHARD-FOY *In* AGARD, Aerospace Software Engineering for Advanced Systems Architectures 9 p (SEE N94-29315 08-61) Nov. 1993
(AGARD-CP-545) Copyright Avail: CASI HC A02/MF A03

The certification procedures apply to a fully developed system including both hardware and software components. The issue is that the equipment supplier must integrate various components coming from separate sources. In particular, the Ada Run Time System is embedded in the equipment like any other application component. This leads to two major requirements: the Ada Run Time System must be a glass box, and unused run-time services must be eliminated from the embedded components. The first requirement comes from the civil aviation procedures DO 178A, and the second is a consequence of the need to proof the system. This can lead to the elimination of some unpredictable or unsafe Ada language features. The criticality of the system consists of three levels: critical, essential, and non-essential. The report ARINC 613 (from the Airlines Electronic Engineering Committee) surveys the Ada language and provides a list of features not to be used in avionics embedded software, at least for the first two levels.

Modern aircraft, military or civil, incorporate the most up-to-date technology from all fields of research and development. There is an increasing tendency to develop digital control systems to replace analog control systems in all areas: engine control, power generation, fuel control, and environmental control. Digital systems are felt to be irreplaceable in avionics, and they are quickly approaching this level in flight control systems. Indeed, digital systems are responsible for the increased sophistication of modern aircraft and for the success of avionics as it now exists. The net result is that, while in the first generation of jet planes there were no onboard computers, modern aircraft may have more than twenty--with single or multiple 32 bit microprocessors, multiple megabytes of RAM, and sophisticated real time operating systems. VALIDATION AND TEST OF COMPLEX WEAPON SYSTEMS
MARK M. STEPHENSON *In* AGARD, Aerospace Software Engineering for Advanced Systems Architectures 12 p (SEE N94-29315 08-61) Nov. 1993
(AGARD-CP-545) Copyright Avail: CASI HC A03/MF A03

As avionics software complexity increases, traditional techniques for avionics software validation and testing become time consuming, expensive, and ultimately unworkable. New test issues arise with the development and maintenance of complex 'super federated' systems like that of the B-2 and highly integrated systems like that of the F-22. Upgrades to existing weapon systems that produce a blend of federated and integrated architectures further complicate the problem. This paper discusses the limitations of current approaches, equipment, and software. It defines a next generation of avionics software validation and test procedures, along with the hardware and software components that are required to make the process work. The central goals of the process and components are to reduce development and maintenance costs, to minimize womanpower requirements, to decrease the time required to perform the testing, and to insure the quality of the final product. The process is composed of unit test, component test, configuration item test, subsystem test, integration test, avionics-system test, and weapon-system test. Some of the topics covered are as follows: automated testing of avionics software, real-time monitoring of avionics equipment, nonreal-time and real-time avionics emulation, and real-time simulation. This paper is based upon several years of experience in the following areas: (1) research and development of new technologies to improve the supportability of weapon-system software; and (2) design and implementation of facilities for the development, enhancement, and test of avionics software. ADVANCED PACKAGING CONCEPTS FOR DIGITAL AVIONICS [LES TECHNIQUES AVANCEES DE MISE SOUS BOITIER]
Oct. 1994 287 p In ENGLISH and FRENCH Symposium held in San Diego, CA, 6-9 Jun. 1994
(AGARD-CP-562; ISBN-92-836-0004-5) Copyright Avail: CASI HC A13/MF A03

A critical impediment to significantly improving the performance of digital airborne electronics or avionics is the limitation posed by current electronics packaging concepts. This symposium brought together experts from seemingly diverse, but interlocking disciplines ranging from logisticians to digital designers to mechanical engineers to establish the current baseline in digital packaging, failure modes of the electronics and support problems. Trends in

both supportability and processing were described for early 21st century application. Along with the projections of asymptotic increase in signal, image and data processing, dramatic increases in thermal densities, chip interconnects, correctors and backplane traffic were described. For individual titles, see N95-20632 through N95-20659.

THE IMPACT OF ADVANCED PACKAGING TECHNOLOGY ON MODULAR AVIONICS ARCHITECTURES

REED MORGAN and JOHN OSTGAARD *In* AGARD, Advanced Packaging Concepts for Digital Avionics 12 p (SEE N95-20631 06-06) Oct. 1994

(AGARD-CP-562) Copyright Avail: CASI HC A03/MF A03

This paper explores how advances in digital packaging will impact network requirements at the system level. Two main issues connected with modular digital packaging for avionics were investigated: (1) Can conventional electrical designs continue to handle the information network speed and wirability requirements needed at the backplane to efficiently utilize advanced modular data and signal processors? (2) Considering projected network requirements for future sensors, displays, etc., (which are made possible because of digital packaging advances), what type of system architecture will be needed? The paper concludes that: (1) Beyond the module (PCB) interface, a new type of backplane implementation will eventually be needed to support the flexibility and growth needs of modular processing. Several new approaches other than a passive electrical backplane could be employed; however, a switched, photonic-based approach is proposed for information distribution between digital processing modules as well as for interconnection between peripherals. Digital packaging advances will result in I/O speeds of about 2 Gigabits/sec, and (2) advanced integrated RF and EO sensors and display technologies will require network data rates in the range of 2 Gigabits/sec in order to communicate in real time with the high speed signal and graphics processor modules in the common integrated processor racks. Many of these 'peripheral' functions will require virtual point-point links because continuous, streaming data in involved. This resulting system architecture recommended is a switched optical network which interconnects sources and sinks of information to the modular processing assets, as well as providing a network for intermodule intercommunication within the rack. Issues of protocol control of this network remain. Further, several advances in photonic packaging and connectors will be required to make this new architectural approach a reality. Although photonics offers the best long-range solution, significant technology difficulties must be overcome. Author

The objective of the 'Advanced SEM-E Packaging' is 'to identify existing SEM-E and modular avionics characteristics; delineate where they are not defined; and document consensual requirements and guidance for military and commercial applications to provide a framework for open systems architecture implementation'. SHARP has teamed with the Air Force Modular Avionics Systems Architecture (MASA) Program to bridge Industry and government agencies in defining and documenting Standard Electronic Module (SEM) format E advanced packaging requirements. The baseline for the working group has been identified, but SHARP and MASA are soliciting participation and input from industry, other agencies, and NATO. Author

Modular avionics is one of the major concepts to be applied to future avionics systems with the objective of cost (LCC - Life Cycle Cost) containment and improvement of operational performance. The objectives associated with such a concept are numerous: improvement of reliability, standardization, interchangeability, interoperability, etc. To obtain these objectives it is necessary to define characteristics standards for modules (LRM - Line Replaceable Module). The definition of these standards for LRM has a direct impact on the modules and their integration. The choice of the best concept takes place through a careful study of the repercussions of each solution on all levels (racks, bays and platforms), in all the technical fields (thermal, electric, mechanical, electromagnetic protection, connectors). This article presents the results of a parametric platform/system-avionics study and more particularly the possible choices for orientation of the platform on aircraft or helicopters. The method used defines the platform constraints to be parameterized and their interactions. The effects are initially integrated in a model representative of standard missions. Thus the results, field by field, show the importance of the effects of constraints on the platform system. Finally, a process of complete dimensioning of the platform, including the functional reliability aspects leads to the synthesis. This allows both a quantitative and qualitative check of the robustness of the compromises carried out. In conclusion, the control of the platform/avionics-system compromise, by an approach of simultaneous engineering, makes it possible to justify a solution of conditioning of the modular avionics in the optics of a future system. The main requirements for modular avionics have a strong influence on the Packaging solutions for the Line Replaceable Modules (LRM's) and the rack. Packaging is here including: mechanical concepts, cooling, power supplies, interconnections and electromagnetic compatibility. To define the packaging solutions for the next generation of avionics, a parametric study, FASTPACK, has been performed at the platform and avionics levels. The present paper deals with the avionics part and shows how the FASTPACK parametric study has been conducted in order to define a synthesis in each domain, used to derive Packaging concepts. The main results include the choice of a LRM format, called FAST, a distributed power supply network within the rack, conduction and liquid flow through cooling, shielding on the rack against external electromagnetic threats and shielding on the LRM for rack internal interferences and, finally, the first definition of the LRM connector. The Navy's Advanced Avionics Subsystem Technology (AAST) Fault Tolerant program is clarifying the Navy's fault tolerant avionics specifications methods and acceptance tests. The goal of the program will be to clarify the Specification and Statement of Work language needed in future procurements and to demonstrate fault tolerant validation tools on the avionics design. A set of tool features will then be developed that spans the needs of fault tolerant computer system design from early concept studies to full scale production and operational support, both hardware and software. The paper will give an overview of the AAST Fault Tolerant Demonstration and focus on two tools that are being used in the demonstration: FERRARI - a software fault injector that will be used to validate the fault tolerance of the Common Integrated Processor (CIP), the F-22 Mission Processor, and GRIND - a concept evaluation tool that will be used to evaluate the overall CIP architecture. There are already several Multi Chip Module (MCM) technologies suitable for avionics applications, and new variations and updates are continually being added. The optimum technology choice for each avionics application will depend on many factors, including the electrical and thermal requirements, the operating environment, size, weight, quantity, cost, etc. This paper will compare the attributes of the various MCM technologies, both at present and future trends, including 3D assembly/packaging and the use of active substrates for MCM-D's. The means of mounting MCM's and interconnecting them into the system using electrical or optical interconnection will also be compared. Some of the methods used to remove very high levels of power dissipation will also be discussed, in relation to the different technologies. The requirements of electronic modules in different parts of avionics systems may be sufficiently different that alternative solutions are optimal for the various parts. The paper will briefly review the range of requirements across military (and comparable civil) avionics systems and, by considering the technology options, indicate how the optimum choice can be decided, both for the MCM's themselves and for the means of interconnection between MCM's and from MCM's to other parts of the system. The U.S. Navy Next Generation Computer Resources (NGCR) High Speed Data Transfer Network (HSDTN) program has chosen the IEEE Scalable Coherent Interface (SCI) as one of its baseline standards. This paper proposes to use SCI as a unified avionics network and describes SCI and extensions to it -- particularly an extension known as SCI/ Real Time (SCI/RT). Because SCI can be used in a serial configuration, such a network provides an alternative to the need for ever denser and ever more reliable backplane connectors by reducing the number and size of interconnects and, hence, the need for large numbers of pins. In addition, SCI reduces packaging problems by using a small amount of board real estate and by using distance insensitive links which can extend board to board or box to box, thus facilitating a distributed backplane approach for retrofit aircraft applications. SCI is currently being applied to both parallel and to serial implementations, to both message passing and shared memory computing paradigms, and to both electrical and optical physical layers. SCI/RT is a set of proposed enhancements, developed initially by the Canadian Navy and now being evaluated by the NGGR HSDTN and IEEE working groups, to make SCI more fault tolerant and to provide the determinism and priorities necessary to support Rate Monotonic Scheduling. Addition of these features will allow SCI to perform in a unified and seamless manner, the functions of command and control interconnect, data flow network and sensor/video network. Electrical and optical, and serial and parallel links can be intermixed for the most cost effective solution. As an added benefit, SCI has potential for use interconnecting multiple processing chips on the same board. Author

Future avionics systems will be based on a modular architecture in which each elementary function will correspond to a line replacable module (LRM). Parametric studies, such as FASTPACK, showed that the optimal solution for the supply systems was an architecture distributed on only one level of energy transformation, i.e., a modular supply on each LRM able to deliver 50 W with 100 W directly starting from the main supply system (270 V(dc) or three-phase network 200 V/400 rectified Hz). In order to obtain a coherent level of integration of the digital circuits, it was necessary to develop such modular supplies with a power density of about 1500 W/dm(sup 3) per unit of volume. In addition, so that these supplies can be established directly on a LRM simple face, their thickness had to be limited to 6.8 mm (case included/understood). To achieve this goal, a total integration that guaranteed the performances of the electric supplies, high frequency hybrid converters (of the order of MHz) were developed. After a presentation of the advantages of an architecture of distributed supply and a review of the main technical aims, this article describes the techniques and technologies implemented to achieve these goals. A thorough description of the developed modular supplies is given for delivered powers ranging between 50 W and 100 W and for various output voltages. Finally, the future developments planned to reach a power density of 4000 W/dm(sup 3) per unit of volume are reviewed. Transl. by CASI

Today's aircraft contain a multitude of different radio functions for communications, navigation and identification. The individual radio functions, like VHF/UHF, JTIDS/ MIDS, GPS or NIS, are each handled by an individual piece of equipment consisting of several LRU. In the absence of built-in redundancy, the failure of a single LRU can result in a failure of a radio function. In the future, individual radio functions need to be integrated in a modular system concept, the modular CNI system (communication - navigation - identification). Author

The preliminary results are presented which were obtained in order to validate the CANARI code in a turbomachinery case. This code solves the Reynolds averaged compressible three dimensional Navier-Stokes equations. It is applied to the flow computation through a high pressure turbine annular cascade. This computation is characterized by the use of a highly stretched O mesh around the blades and of H meshes for the upstream and downstream regions, in order to allow an accurate description of the leading edge and trailing edge phenomena. The configuration studied is an experimental set-up which has been recently realized at ONERA for the validation of computational codes. Author

Capacity and speeds in industrial computer hardware allows the complete numerical evaluation of the three dimensional flow field through turbomachinery blading. Detailed consideration of specific flow phenomena like horseshoe vortex or tip clearance effects is of increasing importance in the engine design process. The large amount of data produced by a 3-D calculation requires separate development of algorithms for visualization of the computational results. Numerical techniques for the integration of both streamlines and vortex lines through 3-D vector fields are needed to identify fluid flow features based on values at discrete grid points. Such an integrated technique is covered and also includes a search algorithm for places of local rotations. Some evaluations of Euler calculations in a turbomachinery application are shown. Author

A complete CFD system, composed of an interactive mesh generator, an efficient flow solver and an advanced, portable, flow visualization system is presented for turbomachinery applications. The mesh generator (IGG) and the visualization system (CFView) have the same user interface and call on Object Oriented Programming on top of X Windows. The flow solver is developed within a multigrid method, where the time integration schemes are considered as 'smoothers'. Both explicit or implicit time integration methods can be chosen. The explicit integration is based on the Runge-Kutta method and the implicit solver uses relaxation methods with Gauss-Seidel point or line strategies. The space discretization allows for central as well as upwind schemes and algebraic or two equation turbulence models are available. The application to an annular turbine blade row is shown. Author

A transonic turbine nozzle guide vane was tested in an annular cascade with two different endwall geometries. The measurements were taken at engine representative flow conditions and include surface static pressures and a downstream area traverse of total pressure. The flow through these geometries was modeled at the test conditions using a three dimensional viscous flow program. The effects of different mesh densities and two turbulence models were studied. Predictions of secondary flow and loss were obtained and are compared with the experimental measurements. The different turbulence models were found to have little effect in the predicted overall loss though there were differences in the distribution and the shape of the vane wakes. The one equation turbulence model produced wakes which had similar levels of total pressure deficit to the experiment and had a more similar shape than those with the Baldwin-Lomax algebraic model. The following problems are discussed. The best approach in order to obtain the average characteristics of the flow field by directly using a three dimensional computation on a complete turbomachinery stage. The real flow is absolutely 3-D and unsteady. This implies that numerical simulation of the flow must be unsteady. Therefore, it is necessary to make more or less rigorous unsteady computation or averaged steady computation can be directly performed. Two different ways to carry out computation on a highly loaded turbine stage are given and analyzed. The steady approach in which the average flow is redistributed at each iteration between both rows, in order to obtain the average steady solution. And the unsteady approach by taking into account several channels on both rows. The computation is purely unsteady with a time periodicity; i.e., if a result is obtained at time t, the same results must be found at time t + T, T being the time period. In these cases, a time average must be made over a period in order to obtain the 3-D flow field average. Author

MODELLING THE VAPORISER AND PRIMARY ZONE FLOWS FOR A MODERN GAS TURBINE COMBUSTION CHAMBER

N. R. BOND, J. M. LEVALLOIS, and K. R. MENZIES *In* AGARD, CFD Techniques for Propulsion Applications 18 p (SEE N92-27450 18-34) Feb. 1992

(AGARD-CP-510) Copyright Avail: CASI HC A03/MF A06

A three dimensional curvilinear finite volume computational fluid dynamics (CFD) code has been applied to aid understanding of the mechanisms leading to observed baseline temperature patterns on a modern vaporizer combustion chamber. This code calculates recirculating, turbulent, combusting flows with a k-epsilon turbulence model and a conserved scalar/local chemical equilibrium combustion model. Predictions were obtained for both the vaporizer internal flows and for the complete flametube; the latter used the predicted vaporizer exit flow patterns as boundary conditions. The vaporizer flow models displayed a sensitivity to the fuel injector location which was subsequently confirmed by water analogy experiments. In conjunction with the flametube calculations, the effect of injector geometry and location on the primary zone flow patterns and temperatures were assessed, explaining the experimental results. The computational studies suggested a modified fuel injector geometry to reduce sensitivity and improve fuel distribution, which was validated by subsequent experiments in the full combustor. Author

Aero-thermodynamic performance prediction methods for gas turbine engines with respect to steady and transient operation are discussed. This includes advanced cycle calculation methods, also taking into account variable cycle engine types. A very important objective is the consideration of installation effects, i.e., Reynolds number and inlet distortions, as well as advanced control concepts for increasing engine surge margins. In addition to these topics, individual papers include practical considerations in designing the engine cycle, dynamic simulation, inlet distortion effects in aircraft propulsion system integration, 'smart' engines, and performance and health monitoring models. For individual titles, see N92-28459 through N92-28467.

(AGARD-LS-183) Copyright Avail: CASI HC A03/MF A02

The basic methods of component matching, which is central to the prediction of gas turbine performance, are outlined. Steady-state prediction of off-design performance must be done at the beginning of an engine development program. This ensures that the engine can satisfy all the mission requirements. The matching techniques can be extended to predict transient performance, which is essential for controls development and to ensure good engine handling. The large amount of computation required demands the use of computer modelling and the role of modelling in the development program and the basic requirements for performance modelling are described. To define the cycle parameters and calculate the performance of a real engine, numerous practical constraints need to be taken into account. These fall into two main categories: the limitations of available component technologies; and the operational considerations that are dependent on aircraft application. The main technology limiters are discussed. How they are incorporated into the cycle definition process is indicated. Operational factors include the extent of the intended flight envelope and the range of the critical flight conditions for which performance must be assured, and the balance to be struck between minimizing fuel consumption, maximizing installed power, and constraining costs of ownership. Taking these technology and operational influences into account, the basic cycle characteristics and approach to cycle choice are examined for three main classes of aircraft: subsonic transports, military combat aircraft, and helicopters. The detailed design and development of turbofans involves the prediction and identification, by means of test analysis, of the performance of the engine and its components. The thermodynamic simulation and analysis codes integrate existing knowledge and interpretations of the detailed operating procedure of the components of the engine being developed. The relevance of the predicted performance depends on the quality of the representation of the various physical phenomena affecting the characteristics of the components and, consequently, on the incorporation of experimental correlation in the modelling. In this context, the representation of compressor and turbine characteristics is particularly important. We will analyze the ability of corrected parameters to represent MACH similitude at the component inlet under various conditions. Author

A tutorial survey of inlet flow distortion effects on engine performance and stability is presented. Inlet distortions in aero engines arise through a variety of causes. They can be essentially steady, due to non-axisymmetric intake duct geometry, or time varying, for example from flow separation off the lip of the inlet during maneuvers or shock-induced separation during supersonic flight. Whatever the cause, the result is generally a decrease in performance and, more importantly, a lessening of the stable flow range of the compressor. The distortions are generally three-dimensional. It is an extremely useful simplification to break them, at least conceptually, into radial and circumferential non-uniformities and approach each separately. Purely radial distortions can be treated by the methods that were developed for designing compressors in nominally axisymmetric inlet flow, and this type of distortion will be only briefly discussed. Circumferential non-uniformities, however, introduce additional fluid dynamic features into the analysis of compressor behavior and often have the larger impact on performance and stability. Thus we concentrate mainly on the effects of steady circumferential inlet flow distortion. Author

CALCULATION OF INSTALLATION EFFECTS WITHIN PERFORMANCE COMPUTER PROGRAMS
J. KURZKE *In* AGARD, Steady and Transient Performance Prediction of Gas Turbine Engines 19 p (SEE N92-28458 19-07) May 1992
(AGARD-LS-183) Copyright Avail: CASI HC A03/MF A02

Gas turbine engine components, such as compressors, burners, and turbines are usually tested on rigs prior to installation into an engine. In the engine, the component behavior is different for a variety of reasons. The installation effects are caused by small geometrical differences due to nonrepresentative rig operating temperatures and pressures, by different gas properties and Reynolds numbers and by radial as well as circumferential temperature and pressure profiles at the inlet to the component. For highly accurate performance predictions these rig-to-engine effects are taken into account. Traditionally the term 'installation' is also used for describing all the differences in engine operation and behavior between testbed and aircraft. Intake and afterbody drag, power offtake and bleed, as well as intake pressure losses and inlet flow distortion have significant impact on airflow, thrust, specific fuel consumption, and compressor stability. Using modern performance synthesis programs all these effects can be simulated. Author

This lecture discusses the use of closed loop control at the component level to enhance the performance of gas turbine engines. The general theme is the suppression of flow instabilities (rotating stall and surge) through use of feedback, either actively or by means of the aeromechanical coupling provided by tailored structures. The basic concepts that underlie active control of turbomachinery instability, and their experimental demonstration, are first described for a centrifugal compressor. It is shown that the mechanism for stabilization is associated with damping of unsteady perturbations in the compression system, and the steady-state performance can thus remain virtually unaltered. Control of instability using a tailored structure is then discussed, along with experimental results illustrating the flow range extension achievable using this technique. A considerably more complex problem is presented by active control or rotating stall where the multi-dimensional features mean that distributed sensing and actuation are required. In addition, there are basic questions concerning unsteady fluid mechanics; these imply the need to resolve issues connected with identification of suitable signals as well as with definition of appropriate wave launchers for implementing the feedback. These issues are discussed and the results of initial successful demonstrations of active control of rotating stall in a single-stage and a three-stage axial compressor are presented. The lecture concludes with suggestions for future research on dynamic control of gas turbine engines. Author

The role of computer modelling in the design, development, and validation of a performance monitoring system is discussed. The basic requirements of an engine health monitoring system are discussed in the context of the user environment. A form of model based on stage characteristics provides the basis for describing engine measurements. Faults are modelled in accordance with empirical data obtained from tests conducted at the stage level. The model is used to investigate various parameters that provide unambiguous identification of the fault in question. Fault libraries were developed for field use. Author

The present contribution describes the measurements of a three-component laser Doppler anenometer (LDA) within the jet of a bypass engine CFM56-5 installed on an A320, in the form of ground tests. The aerodynamic data obtained at the fan exit and in two sections at the turbine nozzle exit near cruise condition allow an insight into the complete jet behavior. The velocity components in the specified position for all three coordinate directions are discussed allowing the evaluation of the radial velocity distribution and the swirl components. In addition, the important parameters of the turbulence intensity and the direction of the thrust vector are considered. Author

A generic matrix of propulsion force accounting procedures was developed from a survey of the U.S. aerospace community. The matrix includes definitions for propulsion system and control volume boundary specification. Aerodynamic reference conditions are also discussed relative to off-design performance. The advantages and disadvantages of each of the force accounting

procedures are discussed as they apply to some typical hypersonic force accounting problems. Author

This report presents a set of six test cases intended to provide support for the development and validation of structural analysis and life prediction codes applicable to gas turbine components. The test cases are based on actual engine simulation tests. The data bases comprising the test cases include geometric design information describing the component, rig interface information, material data, and test condition data including steady, dynamic, and thermal loading. Crack initiation and propagation data are also included. Hence, these test cases, for the first time, make available all of the component and loading information required to verify that existing codes or codes in development yield meaningful and consistent predictions. This Advisory Report was prepared at the request of the Propulsion and Energetics Panel of AGARD. For individual titles, see N93-14891 through N93-14898.

The cost of maintaining fleet readiness and the trend toward higher power to weight ratio gas turbine engines has put increased importance on component structural analysis and life prediction. Over the past decade there has been considerable progress in the development of advanced structural analysis and life prediction codes for gas turbine engine components. The six test cases comprising this document include a collection of problems that consider crack initiation and crack propagation in hot section and cold section engine components. A broad range of component configurations and loading conditions are included as well as a detailed listing of test case attributes. Author

The component test of the LARZAC HP turbine disk proposed in this document provides the opportunity for validation of life prediction methodologies concerning crack initiation and propagation behavior on an area of a nickel-based refractory alloy turbine disk subjected to multi-axial loading. It should be noted, in particular, that this test, carried out under a partial vacuum at high temperature, proposes study of the natural initiation and propagation of a low-cycle fatigue crack. This test case offers the advantages of test analysis of a real turbine part, well defined test conditions, natural initiation of a crack in an area subjected to multi-axial loading leading to moderate plasticity, a well-known nickel-based material (INCONEL 718), and only two-dimensional test analysis, but requiring fine elastic-plastic modeling. The limitations of the test are that it is a component test carried out under isothermic conditions, with a simple load cycle (non-mission), and it involves a complex disk environment (recreating that of an engine) requiring modelling, of the adjacent parts to simulate realistic boundary conditions. From this study conducted by GE and RAE, it was concluded that the test case includes sufficient information to make analytic predictions of fatigue crack propagation behavior, and correlate life predictions with spin pit test results. The RB 199 test case presented here addresses areas with stress concentration to a stress level of local elastic-plastic material behavior. The material used is a corrosion resistant steel X8CrCoNiMo11. Information about component geometry, part processing, operating conditions and history, recommendations about stress analysis and relevant boundary and thermal conditions as well as materials data are presented. This test case deals with cyclic spin pit testing conducted on the 3rd stage HP compressor disk of the TURBO UNION RB 199 engine. The tests were performed to verify disk design and life prediction under a safe life LCF lifting concept. Addressed critical areas are Bolt Holes and Rim Slots. For Bolt Hole testing the original component geometry was modified slightly, for Rim testing significantly to ensure component failure to occur in the area under investigation and local stress distribution as under engine operating conditions. Following an independent analysis, it was concluded that the test case includes sufficient information to generate a viable stress analysis model, generate concentrated stress factors, and correlate life predictions with the spin pit test results. Analyses and the materials data provided in the test cases were used to predict the disk lives for the spin pit testing within 10 percent of the observed lives. Author

The CF6-6 High Pressure Compressor Stage 5 Locking Slot Crack Propagation Spin Pit test case provides the opportunity for validation of stress analysis and crack propagation life prediction methodologies for a complex geometry, titanium material, gas turbine aircraft engine component. The case addresses crack growth from an artificial crack starter notch under isothermal, constant amplitude, continuous (no dwell period), cyclic testing in a partially evacuated spin pit test facility. The most outstanding attribute of the case in the comprehensive crack growth measurement data available in 200 cycle increments throughout the 7355 cycle test duration. The test case included use of actual hardware (field returned, titanium material, engine part); complex local part geometry involving a decaying stress gradient; an elastic-plastic stress level (local area yielding); realistic surface conditions (milled and shot peened surface), and assessment of a significant failure mode. To evaluate this test case, a two-dimensional axisymmetric finite element stress analysis of the compressor spool was completed followed by a two-dimensional finite element analysis of the concentration effect of the loading slot. These results were used to calculate the crack propagation behavior from the crack starter notches introduced at the loading slots. Factors to account for the effect of shot peening were

derived empirically from the results given for the notched bend specimen. These factors were used in the component life calculation which resulted in a prediction within 13 percent of the observed life. The assessment confirmed the suitability of this test case. Author

ENGINE LIFE ASSESSMENT TEST CASE TF41 LP COMPRESSOR SHAFT TORSIONAL FATIGUE
WILLIAM H. PARKER *In* AGARD, Propulsion and Energetics Panel Working Group 20 on Test Cases for Engine Life Assessment Technology 63 p (SEE N93-14890 04-07) Sep. 1992
(AGARD-AR-308) Copyright Avail: CASI HC A04/MF A03

The test case presented here provides an example for crack initiation and crack growth of a shaft loaded with major, zero to maximum, torsional cycles with steady axial load and high cycle minor torsional cycles superimposed. The TF41 LP compressor drive shaft was tested as part of a U.S. Air Force Life Extension Program in the early to mid 1980s. This test program provided a controlled set of fatigue testing information and material characterization data which form the basis of the test case. Details of the engine shaft are presented along with pertinent processing information. The test setup and program are described in sufficient detail to permit users to model the component and predict the state of stress. Material data are presented with enough detail so that fatigue life models can be used to predict the shafting life and comparisons with test results can be made. Author

F100 SECOND STAGE FAN DISK BOLTHOLE CRACK PROPAGATION FERRIS WHEEL TEST
THOMAS E. FARMER *In* AGARD, Propulsion and Energetics Panel Working Group 20 on Test Cases for Engine Life Assessment Technology 48 p (SEE N93-14890 04-07) Sep. 1992
(AGARD-AR-308) Copyright Avail: CASI HC A03/MF A03

This test case provides the opportunity for the evaluation of the overall stress state in a typical 'fracture critical' gas turbine engine rotor component and residual crack propagation life assessment at the bolthole for a simulated low cycle fatigue engine operation mission cycle. Ferris wheel testing provides the crack propagation data to which the prediction is correlated. In addition, an overload hot pre-spin treatment of the disk is evaluated as a means of establishing an induced beneficial near surface compressive residual stress at the bolthole to enhance the crack propagation life. The F100 2nd stage fan disk was tested as part of the U.S. Air Force Damage Tolerant Design for Cold-section Turbine Engine Disks Program AFWAL-TR-81-2045 in the late 70s. The component geometry, part processing, test rig set-up, operating conditions and environment, and materials data are presented in sufficient detail to allow users to model the component and predict the state of stress throughout the body of the disk with particular attention to the bolthole outer diameter location of interest. Solution of the stress state at the bolthole O.D. for the simulated mission cycle and use of crack propagation rate models allow prediction of the residual life from pre-cracks and make comparisons to actual test data. It is believed that the cases reported will be the forerunner of a number of future studies dealing with more complex combinations of factors that need to be considered to assess the life of a gas turbine component in actual service. Some of these considerations are discussed here, in relation to the test cases detailed in earlier chapters. While the focus is upon discs and spacers, to maintain a close relationship with the test cases presented earlier for other engines, blade life prediction is also discussed. Where appropriate, examples were drawn from experience in J85 and F404 engines operated in Canada. This paper considers various practical aspects of life prediction which merit further investigation. These are as follows: small crack behavior; the effect of loading conditions, multiaxial loading, HCF-LCF interactions, creep-fatigue and creep-fatigue-environment interactions; microstructural effects, long term service exposure effects, grain size, and grain shape effects, anisotropic behavior and single crystal turbine blades; coating effects; defects and damage tolerance; inspection sensitivity and reliability effects; residual stress effects; effects of repair; and usage monitoring. COMBUSTION INSTABILITIES IN A SIDE-DUMP MODEL RAMJET COMBUSTOR
J. M. SAMANIEGO, B. YIP, T. POINSOT, and S. CANDEL *In* AGARD, Airbreathing Propulsion for Missiles andProjectiles 17 p (SEE N93-17607 05-20) Sep. 1992
(AGARD-CP-526) Copyright Avail: CASI HC A03/MF A03

Combustion instabilities are often observed in coaxial and side-dump combustors and can be detrimental to their performance. This study is aimed at identifying the physical mechanisms underlying combustion instabilities in these geometries. Recent studies performed on side-dump geometries have focused on hydrodynamic instabilities under non-reacting conditions. The present work was conducted on a two-dimensional two-inlet side-dump combustor, fed with a premixture of air and propane in order to examine reacting flow instabilities. Results from a stable combustion regime are presented in order to provide a basis for comparison with a low-frequency instability mode (520 Hz) which occurs at other combustor operating conditions. The flowfield structure is investigated using high speed Schlieren visualization and conditional C2 imaging. Simultaneous pressure, inlet velocity, and global C2 emission measurements are used to investigate the nature of the instability. Different processes involved in the instability mode are identified such as the acoustics of the combustor, the oscillatory motion of the jets underlying periodic jet-on-jet impingement and a complex behavior of the reaction zones. Furthermore, by obtaining an experimental local Rayleigh index distribution, it has been possible to identify the driving mechanisms of this instability. Author

The increasing effectiveness of future defense systems will lead to projectiles with extremely high impact energy, reduced flight times, and extended ranges. Gun launched projectiles using ramjet propulsion, show promising capabilities in weight, cost, and hit accuracy. If high maximum range and low crosswind sensitivity of projectiles is of primary interest, a compensation of drag can be obtained by ramjet propulsion at low fuel-to-air ratio. Moreover, with respect to applications against armored vehicles ramjet engines operating at nearly stoichiometric conditions, can be even used to increase the kinetic energy of KE-rods. The first part of the paper gives a survey on the main design objectives of ram-propulsion for projectile applications. A detailed theoretical analysis of advantages and limitations is presented for high

performance ramjets. The second part deals with ramjet applications for artillery, air defense, and anti-armor weapons. Due to the high initial velocity provided by guns, ram-propulsion proves to be a very promising and efficient tool in order to meet the demands of future defense systems. Author

Different circular front intakes with shock on lip Mach numbers ranging from 4.5-5.57 were investigated at DLR-Cologne and MBB under funding of the German MOD. The closeable front intake concept (born in 1985) offers high performance at Mach 3.6 transition in combination with exceptionally low drag during boost and cruise. Starting of the essential internal supersonic compression process could be achieved during initial centerbody translation at limited internal contraction and small capture area. A variety of corresponding Hy X intake models having different shock on lip Mach numbers, cowl angles, internal contractions, internal area distributions, and cowl lip bluntness data were tested between Mach 3.5 and 4.5 and gave experience on starting phenomena and performance. Fixed geometry intakes with external compression and quite different cowl angles (RH3A with cylindrical cowl, RH3C with large cowl angle) exhibited comparable or even better total pressure recoveries. The supercritical pre-entry drag characteristics below shock on lip Mach numbers however look most unfavorable. Without consideration of incidence characteristics and the problems associated with closure of intake entrance area during boost, the RH3A-intake could be used instead of the Hy X-type intake for medium range air to ground missiles. The RH3C-intake offers the highest value of total pressure recovery due to maximum external compression and proper cowl alignment. The corresponding high wave drag however prohibits any useful application of this type of intake. Author

The design and development of turbojet engines for missile and target drone propulsion is a field in which MICROTURBO enjoys considerable success. A MICROTURBO engine was selected and is in current development for the APACHE standoff missile. This new single-flow, single-spool turbojet produces 550 daN at Mach 0.8; this gives an SFC figure of 1.10 kg/daN/h at 550 daN and SL Static, which drops to the region of 1 kg/daN/h at 300-400 daN. All this is accomplished by an engine that has a diameter of 343 mm. This preview outlines the tasks carried out to obtain the optimum thermodynamic definition and mechanical design of the engine. Extensive experience in the design of three and four stage compressors of this type was gained by MICROTURBO on their TRI 60 engine family. This experience was used as a basis for the conceptual design of the subject compressor with concurrent intensive use of the 3D EULER code developed by ONERA. The turbine, pre-dimensioned using conventional design methods, was also optimized by means of the EULER code. In a relatively short time, each compressor stage was manufactured then tested separately in the RACE test cell at the CEPr facilities in France, this being closely followed by complete compressor testing, during which performance expectations were met and even exceeded. Major mechanical design requisites for this life-limited engine were minimum maintenance, guaranteed performance, and low-cost production. A feasibility study on production cost effectivity, involving close liaison between the design office and methods department, was initiated in the early stage of the program. Using data provided by external suppliers, various solutions were investigated, the final selection taking into account production cost and risk factors relative to engine and/or missile integration. The result of this investigation is the wide use of castings for rotors, stators, and casings. Maximum simplicity was achieved for engine systems by designing in features such as windmill start capability, a virtually direct drive transmission to the fuel pump and the alternator, and finally, the elimination of the oil lube system. One current focus of propulsion research is to increase gas turbine power density through improved aerothermodynamic component technologies and lower density, higher temperature materials. The objective of increased power density is to decrease engine size for a given output power. For example, increasing power density 100 percent, which is being projected by the 21st century, would be accompanied by a 40 percent reduction in engine size and 40 percent increase in engine speed. The trend towards reduced engine size tasks the ability of the turbojet designer to maintain the high levels of component efficiencies needed and to achieve the projected power density goals. Furthermore, parallel technology improvements projected in propulsion vehicle, system, and electronics technologies, further anticipate engine size reduction. Smaller, smarter airbreathing tactical missiles are being proposed and developed. They will function for various operational duties currently performed by larger, limited range missiles or manned surveillance and interdiction aircraft. The extreme compactness of these advanced missiles requires relatively high power density small turbojets. Several design configuration options are possible for these turbojets including centrifugal and axial turbomachinery compressor and turbines, straight annular and reverse flow annular combustors, and fuel injectors, etc. The attributes of candidate configurations are discussed with respect to maximum thrust per frontal area and low manufacturing cost. This publication presents a semi-empirical approach aimed at studying the internal aerodynamic characteristics of combustion chambers and using this information to predict the performance of various ramjet and strato-rocket combustion chambers. The step suggested, which appeared to be completely operational for numerous treated cases, is based on the joint use of experiments, carried out in isothermal simulated conditions, and of a one dimensional modeling using the concept of elementary jet engines. The experiments are undertaken on hydraulic test rigs or aerodynamic installations using reduced scale models. Conventional techniques of visualization then make it possible to reach the first qualitative description of the flow. Those are supplemented by a certain number of measurements resulting from image processing carried out on preceding visualizations. This quantitative information consisting of the distribution of flow, residence time, and concentration, is then translated into the form of input data for computer code. This calculation, carried out the second time, can use complex chemical kinetics to describe combustion and thus makes it possible to predict, with a good degree of accuracy, the total performance of the chamber (stability limits, combustion output as a function of operating characteristics, etc.,). The interest of such a step during the preliminary draft stage was shown for a significant number of chambers by

comparing the results obtained in combustion with those resulting from calculation. Transl. by FLS

HEAT TRANSFER AND COOLING IN GAS TURBINES [LE TRANSFERT THERMIQUE ET LE REFROIDISSEMENT DANS LES TURBINES A GAZ]
Feb. 1993 492 p 80th Symposium held in Antalya, Turkey, 12-16 Oct. 1992
(AGARD-CP-527; ISBN-92-835-0701-0) Copyright Avail: CASI HC A21/MF A04

The symposium was arranged in the following sessions: turbine blades--external heat transfer; turbine blades--internal heat transfer; measurement techniques; rotating disks, labyrinth seals, and shafts; combustors; design, interactions; and prediction methods. Heat transfer and cooling in gas turbines are still key factors for achieving high performance, increased life, and improved reliability. Any progress in this field will lead to a reduction of maintenance cost and fuel consumption. The purpose of the symposium was to bring together experts from industry, research establishments, and universities to discuss fundamental and applied heat transfer problems relevant to gas turbines, to exchange practical experience gained, and to review the state of the art. For individual titles, see N93-29927 through N93-29964.

KEYNOTE ADDRESS: UNSTEADY, MULTIMODE TRANSITION IN GAS TURBINE ENGINES
ROBERT E. MAYLE *In* AGARD, Heat Transfer and Cooling in Gas Turbines 7 p (SEE N93-29926 11-07) Feb. 1993
(AGARD-CP-527) Copyright Avail: CASI HC A02/MF A04

A theory for unsteady, multimode transition on gas turbine airfoils is presented. The theory, which provides a correction to the Mayle-Dullenkopf multimode model, considers a more physically correct viewpoint by taking into account the periodic disturbance caused by both the wake-induced turbulent strips and the 'becalmed' flow following them. In addition, a comparison of the theory with data is provided, which shows excellent agreement, and results illustrating the effects of transition onset distance and wake-passing Strouhal number on multimode transition are presented. In HP turbines, predictions of the heat transfer to the blade and endwalls is particularly important for an accurate assessment of turbine component life. On the endwalls, there are often complex 3D (secondary) flows present which make predictions of heat transfer particularly difficult. A detailed investigation of this area has been carried out on a fully annular cascade of highly 3D nozzle guide vanes. Measurements were made on the vane and endwalls to determine heat transfer and aerodynamic characteristics. Testing was conducted in a short duration Isentropic Light Piston Test Facility, at engine representative Reynolds number, Mach number, and gas-to-wall temperature ratio. Interpreted test data are compared with computations obtained at test conditions. Author (revised)

Results of naphthalene sublimation measurements and flow visualization studies near the base of round and a square cylinder mounted on a flat plate are compared with similar measurements in the endwall region of a turbine blade. Differences and similarities of the flow and mass transfer are discussed. Samples of mass transfer distribution and visualization results in the region are provided. Supported by the sublimation and the flow visualization results models for the vortex structure in the flow are suggested. Derived from text

The purpose is to try to describe some of the influences on external convective heat transfer of a coolant film whose position varies along the suction side of a high pressure turbine nozzle guide vane. The measurements were performed in the short duration Isentropic Light Piston Compression Tube Facility CT-2 of the von Karman Institute. The effects of external and internal flow are considered in terms of Mach number, Reynolds number, freestream turbulence intensity, blowing rate, and coolant to freestream temperature ratio. The way to evaluate those results in terms of heat transfer coefficient is finally discussed. Author (revised)

The results of a detailed experimental study of the aerodynamic and thermic fields within the boundary layer of a plane wall heated in the presence of localized injections of hot air are presented. For two values of the ratio of jet speed/main flow (0.6 and 1.6) the three components of the flight path vector and the local temperature of the flow are measured in many positions, respectively by Doppler laser anemometry using a cold probe wire. A map of the temperature of the plane wall is obtained by means of an infrared camera. The results show the strongly 3D aspect of the flow downstream from the jet which is dominated by the presence of swirling structures. These last areas generate strong rates of turbulence and have a great influence on the temperature field in the wake of the jets. For the largest of the two speed ratios considered, the cross-flow penetrates under the jets downstream from the injection openings and thus, is in opposition to the heat transfer. Author (revised)

The influence of a spanwise varying, circumferentially uniform inlet total temperature distortion was measured on a transonic turbine stage in a short duration turbine test facility. Large levels of distortion were found to increase rotor blade heat transfer, especially on the pressure surface. A three-dimensional, steady, multi-blade row, Euler code and a streamline curvature calculation were used to interpret the data but did not account for all of the heat transfer increase observed. The effect of unsteady wake flows on blade heat transfer and film cooling effectiveness was experimentally determined by using a spoked-wheel type wake generator. The experiments were performed with a five airfoil linear cascade at the Texas A&M University low speed wind tunnel facility. The mainstream Reynolds number based on airfoil chord length was about 3 x 10 exp 5. The wake Strouhal number was varied between 0 and 0.4 by changing the rotating wake passing frequency. A hot wire anemometer system was located at the cascade inlet to detect the instantaneous velocity, phase-averaged mean velocity, and turbulence intensity induced by the passing wake. A pressure tap instrumented blade was used to measure the surface static pressure distributions and compared well with predicted velocity distributions in the cascade. An instrumented blade without film holes equipped with a thin foil thermocouple was used to determine the surface heat transfer coefficient distributions. The results show that the periodically passing wake promotes earlier boundary layer transition, causing much higher heat transfer on the suction surface. The passing wake also significantly enhances the heat transfer on the pressure surface. The other thin foil thermocouple instrumented blade contained several rows of film cooling holes at the stagnation region and on both the suction and pressure surfaces, and was employed to determine the film cooling effectiveness distributions. The results show that the strong passing wake interacts with the film layer and causes a relatively lower film effectiveness on both the suction and pressure surfaces for all three blowing ratios studied (M = 0.4, 0.8, and 1.2).

Measurements have been made of instantaneous heat-transfer rates to a flat-plate surface under a transitional boundary layer. The thin-film surface instrumentation used in the study was capable of time-resolving the effects of changes in the heat-transfer rate within an accuracy of 10 microseconds. The tests were conducted in the Oxford University 6 inch Isentropic Light-Piston Tunnel (ILPT) under simulated gas turbine Reynolds numbers, Mach numbers, gas-to-wall temperature ratios, and pressure gradients. The ability to observe and track the end stage of the transition process (i.e., turbulent spots) in a laminar boundary layer undergoing transition allowed turbulent-spot convection speeds and spreading angles to be estimated. In these tests, the important fluid-dynamic parameters of Mach number, Reynolds number, and streamwise pressure gradient were varied independently over a wide range of values characteristic of those encountered in the turbine environment. Using quantitative values of the measured turbulent-spot characteristics, a simple time-marching code was developed based on Emmons' turbulent-spot theory to estimate the intermittency. The paper brings together recent research at UMIST directed at the prediction of flow through tight, square sectioned U-bends rotating in orthogonal mode. The cases of flow through rotating straight ducts and stationary U-bends are considered first to allow comparison with experimental data; finally, having demonstrated the level of accord achieved with experiment, predictions for the rotating U-bend are provided. A fairly simple turbulence model was adopted with the usual high Reynolds number k-epsilon model being interfaced with a 1-equation near-wall model. To achieve, in the case of the U-bend, grid independent behavior with the available computer core, a bounded third-order discretization of convective transport had to be applied to all dependent variables. The agreement with the available experimental data is broadly satisfactory in the case of the rotating straight duct (the substantial modifications to the Nusselt number on the pressure and suction faces of the duct due to Coriolis and buoyant forces being well reproduced. Agreement is less complete in the case of the U-bend but even so, the predicted levels of Nusselt number and the distribution of velocity downstream of the bend are broadly in line with experiment. The results point to the desirability of incorporating second-moment closure into the bend-flow calculations as models of this type have a track record of capturing the sensitivity of the turbulent stresses to complex strains better than the eddy viscosity model adopted here. COOLING GEOMETRY OPTIMIZATION USING LIQUID CRYSTAL TECHNIQUE

G. LODIGIANI, A. TROVATI, L. PACI, and P. PIRRELLI (Elasis S.C.p.A., Brindisi, Italy.) *In* AGARD, Heat Transfer and Cooling in Gas Turbines 12 p (SEE N93-29926 11-07) Feb. 1993

(AGARD-CP-527) Copyright Avail: CASI HC A03/MF A04

Experimental results concerning the cooling performance of jet engine blading internal passages are presented. Use was made of the Liquid Crystal Transient Technique in order to obtain detailed information about heat transfer coefficients on the internal blade surfaces in presence of turbulence promoters. A peculiar behavior of the cooling channels with turbulators was detected, which reduces the expected heat transfer effectiveness. Heat transfer experimental results, reproducing actual engine operating conditions, were employed to predict the blade metal temperature: cooling flow parameters and internal channel characteristics were therefore tuned in order to attain a suitable metal temperature distribution, and to optimize the cooling effectiveness. The outcome of experimental and calculation work was then compared to the engine test blade surface temperature distribution, obtained by means of thermal paints. The comparison showed fairly good agreement, demonstrating once more the usefulness of the Liquid Crystal Transient Technique in allowing designers to improve present blade cooling devices. An overview and summary of test methods and results are given for the problem of measuring local heat transfer on rotating surfaces that model gas turbine engine disks. Disk cavity situations generically similar to those encountered in the high pressure stage disk cooling are considered, with cooling air supplied both at or near the wheel centerline as well as through single or multiple jets impinging outboard on the wheel near the blade attachment region. In some situations provision has been made for ingestion

into the disk-cavity from the gas path region radially outboard of the disk. Local heat transfer rates in all cases are determined from the color display from a thin coating of encapsulated liquid crystals sprayed onto the disk, in conjunction with use of a video camera and computer vision system. For cases with axisymmetric disk surfaces, the coated surfaces are illuminated and viewed continuously, and detailed radial distributions of local Nusselt number are obtained. For non-axisymmetric disk surfaces, such as encountered in the vicinity of bolt heads, the disk is illuminated with stroboscopic light, and a method has been developed and used to synchronize the computer frame grabber with the illumination. Heat transfer measurements were made in a five-cavity compressor drum rig, in which cooling air passed axially through the center of the discs. The rig also contained a central drive shaft which could be either co- or contrarotated. Tests were conducted for different mass flow rates, rotational speeds and air temperatures. Typical engine conditions for steady state and transient operating conditions were simulated. Local Nusselt numbers were obtained for the discs of one cavity and compared with other published results. Furthermore an investigation into the effect of co- and contrarotating shaft on the surface temperatures of the discs and on the Nusselt number distribution was also carried out. It was found that the direction of rotation and speed of the shaft influenced the disc temperatures as well as the Nusselt numbers. Author

The operating temperatures of turboshaft engines oblige the manufacturers to cool the parts of the engine located downstream from the combustion chamber and in particular the turbines. Knowledge of the air flow in the air ventilation paths is essential to optimize the cooling of the engines. In order to precisely determine the phenomena of heat exchanges and the aerodynamic forces on the walls of complex cavities, SNECMA uses the MATHILDA code developed with ONERA. The MATHILDA code solves the three dimensional Navier-Stokes equations for flows of compressible fluid. The equations are treated using a finite volume method accomplished on a mesh structure. The resolution scheme is decentered by the order of 2. An implicit method of the ADI type makes it possible to stabilize and accelerate the calculation. This article presents the work of the validation of the MATHILDA code for applications to the flows in interdisc cavities. The cases presented were studied by the implementation of the axisymmetric two-dimensional version. Two types of experimental cavities served as the validations, rotor/stator cavities and rotor/rotor cavities. The solutions obtained, compared with the experimental measurements, are satisfactory, from an aerodynamic point of view and a thermal point of view. The last calculation, on a real configuration of the internal cavity of the engine, makes it possible to apprehend the difficulties encountered in the implementation of this type of modeling, and to measure the contribution of the code solving the Navier-Stokes equations to the description of the cooling flows. The thermal behavior of discs and casings in gas turbine engines has important effects on engine performance and integrity and theoretical or computer modelling of these effects is an essential part of the design process. In this paper the current status of thermal modelling is reviewed, problem areas are identified, examples of where application of the latest numerical and modelling techniques have led to improvements are given, and prospects for further developments are discussed. It is concluded that, although recent research and computing advances are improving the predictive capability, considerable scope for further improvement remains. Author

The paper provides both a brief review of some recent research into the flow and heat transfer associated with the turbine and compressor discs of gas turbine engines and some new results for flow between contra-rotating turbine discs. Elliptic solvers, parabolic solvers and integral methods have all been applied successfully to some important axisymmetric boundary-layer-dominated flows, and multigrid elliptic solvers used in conjunction with parallel computers offer great promise for the future computation of nonaxisymmetric flows. LDA velocity measurements and computations have given fresh insight into the flow between contra-rotating turbine discs. Batchelor-type flow, in which there are boundary layers on the discs and a shear layer in the midplane, has been computed for laminar flow but has not been observed in practice, even at local rotational Reynolds numbers as low as 2.2 x 10(exp 4). The actual flow structure comprised radial outflow in boundary layers on the discs and a central core of radial inflow in which rotational effects were weak. Although the flow in the core was always turbulent, the flow in the boundary layers was laminar for rotational Reynolds numbers up to at least 1.2 x 10(exp 5). Agreement between the computed turbulent velocities and the measured values was good for Reynolds numbers above 4.5 x 10(exp 5). Author (revised)

A new experimental and numerical research program was conducted to determine the effects of rotation on the leakage loss and the heat transfer coefficients of compressible flows in modern high performance labyrinth seals. In this study, the interest is focused on divergent shaped stepped labyrinth seals. That type of labyrinth seal is the last one within a row of different labyrinth seals, investigated at the University of Karlsruhe: straight-through, staggered labyrinth seals and convergent shaped stepped labyrinth seals have been the other geometries. For heat transfer and leakage loss measurements our high temperature test facility was used, providing realistic conditions of gas temperatures, pressure ratios as well as a wide range of axial and peripheral Reynolds numbers. In addition, numerical codes have been verified by experimentally obtained data. Heat transfer coefficients for the stator and the rotor are derived utilizing the well-known standard k-epsilon model and the Stanton-analogy. This report discusses some new rotational effects, which are significant for the divergent shaped seal. In addition, these results are compared with those

obtained from our other seal geometries studied.

The aerothermal design process applied to a Nozzle Guide Vane of a gas-generator axial-flow turbine for a compact advanced technology core engine is described. The principal characteristics of the NGV are: Overall Tip Radius, 108.8 mm; Blade height, 19.7 mm; Blade aspect ratio, 0.53; Solidity, 1.37; Mean Exit isentropic Mach Number, 0.95; Inlet Temperature, 1450K. The NGV is cooled by a combination of different solutions, like impingement cooling and film-cooling on the front side, and forced convection on the rear side, followed by a cooling ejection at pressure side near the trailing edge. Representative results of the computational fluid-dynamics and of the thermal analysis of the NGV blade, together with some experimental data obtained from component test rig and engine demonstrator are presented and discussed.

Air ejection for film-cooling affects the aerodynamic behavior of the blading by the mixing of the coolant with the mainstream as well as by the interaction between the jet and the boundary layer. The main objective is to receive more information on the flow field in the leading edge region. The focus is the aerodynamic behavior of ejection in the stagnation region. A Navier-Stokes code was used to evaluate the flow field considering the ejection. The calculated results are compared with experimental investigations. Cold gas experiments were conducted in a cascade wind tunnel on three large scaled turbine blades with slotted leading edges. The mass flux ratio was varied from 0.0 to 2.5 to simulate film cooling effects. A high resolution of the flow field especially close to the wall (nearest distance: 50 microns) was achieved by Laser-2-Focus measurements. The pressure distributions on the blade surface and in the wake were measured in order to determine the overall behavior of the blades quantitatively while oil flow patterns and Schlieren pictures provide qualitative results. The experimental results show that the strong pressure gradient near the stagnation point affects the velocity distribution of the jets. This non-uniformity produces additional aerodynamic losses. To take these effects into account for the Navier-Stokes calculation a multi-block grid was used to model the flow field in the ejection holes and in the mainstream. Thus, the experimental and numerical results show a good agreement. Author (revised)

The high temperature level reached in the first turbine stages requires efficient blade cooling. Film cooling has proved its ability to protect the wall from the hot upstream flow. However, the jets strongly disturb the aerodynamic flow characteristics. As a consequence, the main objective of the designers is to get the best compromise between thermal strains and aerodynamic losses. A two-dimensional viscous flow model, with discrete jets and based on a boundary layer concept, was developed at Ecole Centrale de Lyon. The turbulence closure was first performed by a mixing length model. A low Reynolds number version of a k-epsilon model is presented. A space averaging method in the transverse direction is used; thereby the two-dimensional character of the computation is preserved, while the specific effects of the discrete jets are taking into account in the model. Comparisons with experimental results are given in the case of a row of jets, as injected through a turbulent boundary layer on a flat plate, near the injection orifice. Author (revised)

The problem of cooled gas turbine blades is theoretically investigated. The presented code solves the 3D-Reynolds averaged-Navier-Stokes equations for the external passage flow and the 3D-heat conduction equation for the interior of the blade. Both calculation schemes are coupled without any modeling of the heat transfer boundary conditions at the blade surface. Calculations are presented for a thin hollow flat plate and a typical guide vane blade with a simple cooling channel configuration. Both geometries are cooled by prescribing fixed heat transfer boundary conditions at the inner boundaries. Additionally numerical results are compared to analytical data. The agreement is quite satisfactory. Author (revised)

The numerical simulation of transonic flows through film-cooled turbine cascades is described. The modelization of coolant injection was implemented in a computational code which solves either the laminar or the Reynolds-averaged Navier-Stokes equations in cascades. Turbulence effects are accounted for by means of the eddy viscosity concept. Two turbulence models were implemented in the code. The first is the Baldwin-Lomax algebraic model and the second is the two-equation k-omega model proposed by Wilcox. Both models were coupled with a Navier-Stokes solver in a simple, robust, and efficient way. The numerical solution of both the flow and the turbulence model equations is based on a cell centered finite volume scheme and on an explicit Runge-Kutta method for time integration. The code was applied to compute the transonic flow in a cascade of nozzle guide vanes (NGV's) developed by Alfa Romeo Avio S.p.A. The computations were performed both for a cascade of 'solid' vane profiles and for a cascade of 'cutted' vane profiles that allow coolant flow ejection through a slot on the pressure side near the trailing edge. The NGV cascade is still under testing and at present only the experimental data for the 'solid' NGV cascade are available for code validation. The computational results presented show that the proposed coupling of the k-omega model with the explicit Navier-Stokes solver does not seem to suffer from the stiffness problems often characterizing other two-equation turbulence models. A numerical method for solving the three-dimensional, Navier-Stokes equations for unsteady, viscous flow and heat transfer through multiple turbomachinery blade rows is presented.

The method solves the fully three-dimensional Navier-Stokes equations with an implicit scheme which is based on a control volume approach. A two-equation turbulence model with a low Reynolds number modification is employed. A third-order accurate upwinding scheme is used to approximate convection terms while a second order accurate central difference scheme is used for the discretization of viscous terms. A second-order accurate scheme is employed for the temporal discretization. The numerical method is applied to study the unsteady flow and heat transfer field of the High Pressure Fuel side Turbo-Pump (HPFTP) of the Space Shuttle Main Engine (SSME). The stage calculation is performed by coupling the stator and the rotor flow fields at each time step through an over-laid grid. Numerical results for the complete geometry with the vane trailing edge cutback are presented and compared with the available experimental data.

The constant amplitude and flight simulation (TURBISTAN) fatigue crack growth behavior of Ti6Al-4V fan disc forgings tested in the AGARD engine disc cooperative test program was investigated by fractographic and microstructural analysis. The crack growth curve shapes and fractographic characteristics were similar. Transitions in the fatigue crack growth curves correlated with a change from structure-sensitive to continuum-mode crack growth, primarily in the transformed and aged Beta grains, and decreased fracture surface roughness. The transitions were most probably caused by the maximum plane strain cyclic plastic zone sizes becoming equal to and exceeding the average platelet Alpha packet sizes. The significance of such transitions for prediction of fatigue crack growth and service failure analysis is discussed.

The low cycle fatigue behavior of the titanium alloys IMI 685, Ti-17 and Ti-6Al-4V tested in the AGARD Engine Disc Cooperative Test Program are described. Load controlled low cycle fatigue tests were carried out on smooth cylindrical and flat double edge notched specimens at room temperature. The test results were statistically analyzed and discussed. The tests showed that the differences in low cycle fatigue behavior between IMI 685 and Ti-6Al-4V are negligible and that Ti-17 has superior low cycle fatigue properties. Author (revised)

The fatigue crack growth results for the titanium alloys IMI 685, Ti-6Al-4V and Ti- 17 that were tested in the Supplemental phase of the AGARD SC.33 Engine Disc Cooperative Test Program are presented. The fatigue crack growth work was carried out under load control using compact tension and corner crack specimen geometries. Tests were conducted under the following loading conditions: constant amplitude ($R = 0.1$ and $R = 0.7$), constant amplitude ($R = 0$) with minor cycles, an $R = 1.7$ single overload sequence and the cold TURBISTAN variable amplitude sequence. The data is presented using a point to point or secant method. The constant amplitude and single overload data base was subsequently used by five participating laboratories to predict a series of 60 load cases using their respective crack growth prediction models. Methods to quantify nondestructive inspection (NDI) reliability and capability have been evolving for over twenty-five years. Initial attempts were qualitative rather than quantitative. With the advent of damage tolerance methodologies, it has become imperative to express more accurately probability of detection for a given inspection method and inspection system. This Lecture Series is aimed at providing a methodology to quantify probability of detection. This methodology includes, but is not limited to, design of experiments, specimen generation and maintenance, statistical analyses, data reduction and presentation, evaluation of inspection results in retirement for cause decisions, and the procedure required to establish a reliable probability based inspection for detecting anomalies in engine parts. The material to be presented is applicable to civil as well as military aircraft and turbine engine manufacturing and maintenance organizations. The lectures will examine the detection capabilities of fluorescent penetrant inspection, eddy current, ultrasonic, and magnetic particle inspection. This Lecture Series incorporates lessons learned in the design of experiments to validate nondestructive evaluation (NDE)/NDI systems and in the interpretation of the results of these experiments. Samples of specimens used in NDE/NDI reliability programs will be available for inspection by attendees. The Lecture Series also includes examples to help with the understanding of design of experiments and the statistical modeling for probability of detection analyses. This Lecture Series, sponsored by the Structures and Materials Panel of AGARD, was implemented by the Consultant and Exchange Program. Author (revised)

Effective computational simulation procedures are described for modeling the inherent multi-disciplinary interactions for determining the true response of propulsion systems. Results are presented for propulsion system responses including multi-discipline coupling effects via (1) coupled multi-discipline tailoring, (2) an integrated system of multidisciplinary simulators, (3) coupled material-behavior/fabrication-process tailoring, (4) sensitivities using a probabilistic simulator, and (5) coupled materials/structures/fracture/probabilistic behavior simulator. The results show that the best designs can be determined if the analysis/tailoring methods account for the multi-disciplinary coupling effects. The coupling across disciplines can be used to develop an integrated interactive multi-discipline numerical propulsion system simulator. Author

A major concern affecting the operation of Advanced Short Take-Off and Vertical Landing (ASTOVL) aircraft close to the ground is ingestion by the aircraft intakes of engine hot exhaust gas. This hot gas reingestion (HGR) can produce loss of engine thrust and erode engine stability margins. A prime source of HGR is the flow occupying the region in the 'near' and 'mid' fields around the aircraft. The 'near-field' flow can be controlled by aircraft-mounted anti-HGR devices but these are likely to be less effective in containing the mid-field flow which is greatly influenced by headwind. Near and mid-field ingestion on Harrier-type configurations has, for many years, been studied by means of model-scale experiments. In most cases in the United Kingdom, the experiments have been set up observing scaling procedures which include consideration of the buoyant action of the hot gas and imply tests at low jet velocities with dynamic head similarity maintained. It can be argued that low velocities may not be appropriate for currently-conceived ASTOVL aircraft employing high pressure-ratio supersonic exhausts, and it may be more appropriate to test at full-scale nozzle pressure ratios. This paper reviews the effects of headwind on HGR for Harrier-type configurations during landing maneuvers with tests carried out both at low jet velocities consistent with buoyancy scaling (NPR(sub F) = 1. 07) and at velocities representative of full-scale nozzle pressure ratios (NPR(sub f) = 2.46). The HGR results are examined in relation to expectations of the forward-flowing gas cloud height and penetration distance for the engine exhaust streams while under the influence of headwinds. The ingestion of engine exhaust gases into an aircraft intake during jet-lift Advanced Short Take-off and Vertical Lift (ASTOVL) aircraft operation close to the ground is an area of considerable concern and has been the subject of much experimental study. The recirculatory flows follow complex paths which are strongly influenced by interference with the ground, aircraft structures, adjacent jet streams, and by the action of an oncoming headwind. The flows are turbulent at a large scale and unsteady with 'streaks' of hot gas entering the intake in a random manner. This Hot Gas Reingestion (HGR) can erode engine stability margins in a region of aircraft operation where reliable engine performance is critical. To ensure engine stability, sophisticated analysis techniques are required to enable prediction of worst-case destabilizing temperature distortion levels for chosen aircraft/engine combination. This paper describes the development and application of statistical analysis techniques designed to examine results of model experiments. These techniques enable quantitative conclusions to be reached as an extension to qualitative examination of trends from observed data. Due to the nature of the flow and distortion parameter, observed HGR data distributions are frequently not normal (Gaussian), and standard statistical techniques cannot be used. Author (revised)

Film-cooling air ejection affects the aerodynamics of turbine blades by the mixing of the coolant with the mainstream as well as by the interaction between the jet and the boundary layer. In the present paper, these effects are studied experimentally and numerically. The results show that the flow in the coolant channel is strongly affected by the main flow around the blade, leading to significant deflection of the coolant air jets. To account for these interactions between the cooling jet and the main flow in the numerical predictions, a multi-block technique is applied. With this technique very complex but structured geometries can be modelled by simply attaching grids of the different sub-domains. For the present investigations, these sub-domains are the two coolant channels at the leading edge and the main flow around the blade. For adaption to the curved geometry of such a turbine blade, a non-orthogonal body fitted grid is used for solving the time average two- or three-dimensional compressible Navier-Stokes equations by a finite volume method. The turbulence is taken into account by the standard k-epsilon model. For discretization of the convective terms the Monotonized-Linear-Upwind scheme (MLU) is used. The pressure-velocity coupling is achieved by the SIMPLEC-algorithm for compressible flows. The calculated results are compared with experimental investigation performed with a L2F-system at a large scaled turbine blade. Three typical blowing ratios are presented. Due to the simultaneous calculation of the coolant flow and the main flow, good agreement was obtained. Author

This paper focuses on the calculation of the flow and scalar fields of axisymmetric gas turbine combustion chambers with non-premixed combustion. Modelling of the turbulent swirling flow is carried out both by viscosity and Reynolds stress closure. It is our intention to specify the shortcomings as well as the potential of the different schemes with regard to prediction capabilities, numerical performance, and economic worth. The various aspects of modelling are discussed. A short description of the governing transport equations as well as the turbulence closure is given. An equilibrium chemistry model is compared to a laminar flamelet model, both schemes applied in conjunction with a probability density formulation for scalar properties. Numerical results of velocities and temperature in model gas turbine combustion chambers are compared with experimental results. Probable reasons for deviations are deduced and some prospects for possible future development of numerical simulation of gas turbine combustion are given. Author (revised)

A method is presented for calculating steady three-dimensional two-phase turbulent reactive flows with curved irregular boundaries. The gas phase equations are solved in an Eulerian frame of reference by a numerical technique based on the finite volume approach, while the equations describing droplet motion, evaporation, and burning are treated in a Lagrangian frame of reference. Turbulent transport is described by the standard k-epsilon model. The combustion model utilizes a conserved scalar formulation and an assumed shape probability density function to account for chemistry-turbulence interaction. The numerical scheme employs structured non-orthogonal grids, a node-centered variable arrangement, and Cartesian velocity components. A special interpolation procedure is used to avoid checkerboard oscillations due to pressure-velocity coupling, and a low diffusive and bounded scheme is introduced to approximate the convective terms in the transport equations. The capabilities of the numerical procedure are demonstrated by simulating an annular combustion chamber for which experimental results were available. The agreement between calculation and experiments ranges from fair to good.

Multidimensional computational combustion dynamics has been used over the last twenty years to provide improved insight during gas turbine combustor design and development processes. The empirical/analytical combustor design methodology that was first demonstrated under the Army sponsored Combustor Design Criteria Validation program conducted during 1974-1978 has been used in the design and demonstration of 15 advanced rig combustors, four technology demonstrator engine combustors, three engine combustors, and one small turbine augmentor. Recognizing the limitations of turbulent combustion models, numerics, and the assumptions required to fully specify the boundary conditions for practical gas turbine combustion systems, a new technique that combines state-of-the-art turbulent combustion models with 'consistent' macro-volume expressions ('hybrid combustor modelling') was proposed. This hybrid modeling approach has been calibrated with combustors that include diffusion flame, lean premix/prevaporized, or rich-lean types of combustion processes. The hybrid modeling technique gives good 'quantitative' agreement with measured data on gaseous emissions, smoke, combustion efficiency, lean blowout fuel-air ratio, pattern factor, liner wall temperature levels, and gradients of a number of combustors.

A typical small gas turbine combustor is modelled using CFD, and the numerical results are compared with laser doppler velocimetry (LDV) measured data. The predicted flow characteristics are in excellent agreement with the measurements. Some aspects of CFD application in combustor design are discussed. CFD can be used in the following ways: as a tool in studying the flowfield development; in the optimization of location, size, and quantity of flow devices; in monitoring flow performance; and in correlating important design parameters. Use of CFD can significantly reduce the lapse time and the development cost of gas turbine combustors. Author

The objective of the Innovative High Temperature Aircraft Engine Fuel Nozzle Program was to design and evaluate a nozzle capable of operating at a combustor inlet air temperature of 1600 F (1144 K) and a fuel temperature of 350 F (450 K). The nozzle was designed to meet the same performance requirements and fit within the size envelope of a current production dual orifice fuel nozzle. The design approach was to use improved thermal protection and fuel passage geometry in combination with fuel passage surface treatment to minimize coking at these extreme fuel and air temperatures. Heat transfer models of several fuel injector concepts were used to optimize the thermal protection, while sample tube coking tests were run to evaluate the effect of surface finish, coatings and tube material on the coking rate. Based on heat transfer analysis, additional air gaps, reduced fuel passage flow area and use of ceramic tip components reduced local fuel wetted wall temperatures by more than 200 F (100 K) when compared to a current production fuel nozzle. Sample tube coking test results showed the importance of surface finish on the fuel coking rate. Therefore, a one micro-inch (0.025 micron) roughness was specified for all fuel passage surfaces. A novel flow divider valve in the tip was also employed to reduce weight, allow room for additional thermal protection, and provide back pressure to reduce the risk of fuel vaporization. The fuel nozzle was fabricated and evaluated in a series of high temperature coking tests. Initial results of these tests indicate that thermal protection and surface treatments were partially successful in preventing nozzle fouling, but additional refinement of the internal flowpath is needed to prevent buildup of coke particles that partially blocked the spin slots which meter the nozzle fuel flow. Three low NOx gas turbine combustor design concepts, Jet Mix, Grid Mix and radial swirlers, which have been demonstrated to give very low NOx emissions using gaseous fuels have been successfully tested on liquid fuels and low NOx emissions demonstrated. The Jet Mix was shown to have low NOx emissions at atmospheric pressure and has been tested at pressure, with similar low NOx results. Kerosene performance and emissions was very similar to that for propane as the fuel. The scale up of the Jet Mix was found to be possible without increasing the NOx emissions greatly and is a preferable design option to the use of large numbers of smaller Jet Mix modules. Sector tests at pressure showed the Jet Mix design produced emission reductions close to the best of the NASA clean combustor results. The Grid Mix low NOx design was shown to be capable of low NOx performance using kerosene. There was a much wider flame stability than for the Jet Mix design and lower NOx emissions were demonstrated. The radial swirler with vane passage of 76mm wall fuel injection was shown to have ultra low NOx emissions with liquid fuels, only slightly higher than for gaseous fuels. For a high air flow radial swirler it was found that central kerosene injection gave lower NOx emissions than for gaseous fuels and had the potential to yield a NOx EI of below 10 at simulated take off conditions. A unique test capability has been defined and used at the United Technologies Research Center to evaluate the transient response of advanced gas turbine combustors. This UTC Transient Combustion Facility offers the opportunity to achieve pre-defined time variations of the air and fuel flow rates and air temperature delivered to a combustor model. This capability can be used for model scales ranging from multi-nozzle combustor sectors to smaller setups focusing on one component or process. A dedicated control computer aids in establishing time profiles for the input parameters and automatically executing the transient test. Among its applications, the facility has been used to study the occurrence of in-nozzle fuel vaporization during Bodie cycles and to assess the tolerance of a fuel-staged combustor to rapid fuel redistribution. To develop a component of an advanced aircraft engine, heavy experimental activities are necessary. To avoid very long and expensive test campaigns on development engines, tests on the so-called technology rigs are fundamental. Particularly in the case of combustion components, whose analytical simulations by means of computer code are still not completely satisfactory and where very high gas temperatures may cause important problems of mechanical integrity, it is essential to check the behavior of the component on the rig before testing on the engine. This paper gives an overview of the test rigs which are used by FiatAvio in the development of the afterburner system for an advanced fighter aircraft engine. The tests which are carried out on these rigs are described and some of the most important results are reported, discussing the benefit they have given to the engine development. Even if this paper obviously does not cover all the results obtained from rig tests over years of engine development, the few examples reported clearly show the importance of these rigs and confirm that the financial outlay to build and update the rigs, test plants and models is worthwhile. Russia has a long tradition of achievement in ramjet research and development. The need for new and effective products has led to the establishment of ramjet research as a priority in Russian research and development. This Lecture Series will present and discuss the scientific problems associated with the development of ramjets/scramjets and turboramjets. Some specific aspects of liquid/solid ramjet development, the concepts of LH2 high efficiency RAM combustors, the results of full scale turboramjet testing, scramjet or CFD analyses, and ground flight tests will be studied. This Lecture Series, endorsed by the Propulsion and Energetics Panel of AGARD, has been implemented by the Consultant and Exchange program. For individual titles, see N94-29292 through N94-29301.

In this report on turboramjet engines, some of the properties of variable cycle propulsion plants based on a combination of ramjet and various turbine-type engines are considered. Various measures of engine thrust performance vs. Mach number are represented. Turboramjet engines (TRE) are classified according to their manner of energy transfer to the ramjet parts. The defining principles of essential TRE propulsion plant working parameters are considered. TRE's with various levels of thrust performance are presented. An effectiveness comparison of various combined propulsion plants for future hypersonic transport planes and a TSTO first stage with LH2 fuel is given. A preference is shown for the turboramjet engine as a universal multimode propulsion plant. The optimization of operating modes in response to changing conditicns is adopted as an approach to governing the operation of a combined engine working process. Author (revised)

Solid propellant ramrockets (SPRR) combine the exclusive operational advantages of solid rockets with the higher fuel efficiency of air breathing engines. The specific feature of an SPRR which differs from a liquid fuel ramjet is the arrangement of the ram combustor in which the products of the primary burning of the solid propellant inside the gas generator are injected through nozzles and reburned. The second feature of the SPRR combustion process is that the gas by-products of primary gas generator are reburned in the ram combustor as turbulent or quasi-turbulent gas flames. Usually there is no need for special flameholders. These special features can lead to some peculiarities in the inserted booster case and to rather complicated gasified fuel supply devices. The third special (negative) feature of SPRR is the constant or programmed fuel supply rate during the flight. Hence, the problem of SPRR fuel flow rate control arises. This lecture discusses the following topics: integration of SPRR with a booster rocket engine; the energy capabilities of different ramjet solid propellants and their application; the effectiveness of secondary fuel combustion in the ram combustor; model and full scaled ramrocket ground testing; and fuel flow rate control in ramrockets. SOME PROBLEMS OF SCRAMJET PROPULSION FOR AEROSPACE PLANES. PART 1: SCRAMJET: AIMS AND FEATURES
A. ROUDAKOV *In* AGARD, Research and Development of Ram/Scramjets and Turboramjets in Russia 20 p (SEE N94-29291 08-07) Dec. 1993
(AGARD-LS-194) Copyright Avail: CASI HC A03/MF A03

This lecture addresses problems of scramjet propulsion for single-stage aerospace planes. The aerospace plane main objective is acceleration of some payload up to orbital speed. It defines a requirement for the propulsion system to be frugal in the wide flight speed range under conditions of propulsion mass limitation and thrust compared with flight vehicle weight. In accordance with modern estimations, real hydrogen fuel scramjet specific impulse may be several times more than that of a rocket engine in the wide flight speed range, from Mf = 5...6 up to Mf = 15...20. But hydrogen scramjet propulsion requires significant air ram connected with high heating of vehicle structure, large hydrogen tanks (and vehicle), and special forms of the flight vehicle. As a result the scramjet advantage, as well as any other air breathing engine advantage, over the modern liquid rocket engines is not doubtless. Nevertheless scramjets can provide good efficiency in aerospace planes if each scramjet element and units are developed very carefully and have high performances. In another case, scramjet may lose competition with liquid rocket engines and a full scale scramjet will be never created. Theoretical and experimental investigations, ground and flight model tests have demonstrated the possibility of supersonic combustion ramjet for hypersonic flights. But we must carry out serious investigations to obtain high efficiency of scramjet elements and scramjet propulsion as a whole to be sure of scramjet success in aerospace plane competition with liquid rocket engine. The computer analysis of scramjet flow became of great importance because of the limited possibilities of ground tests and difficulties of measurements in high speed/enthalpy flows. This fact is a powerful stimulus in CFD development. A short description and examples of applications of the mathematical model for scramjet duct flow developed in CIAM are presented in this paper. Integral liquid fuel ramjets (LFRJ) have some specific features influencing their arrangement and construction. Among such features are: a larger size and working duration than solid propellant ramjets (SPRR), the necessity of fuel manifolds and flameholders, the wall cooling system arrangement in the combustion chamber, and the possibility of fuel flow and nozzle position control during flight on different speed/altitude trajectories. This lecture will discuss some items concerning the mentioned LFRJ features: the integration of ram combustor and booster; duct flow instability during the ejection of booster case; fuel supply device and effective combustion in ramjet; and adaptive control of ramjet on different flight trajectories. In this report, some results of the TRE operating process including those performed on specially developed demonstrator engines are considered. Essential technical requirements and design features of the experimental TRE designed and developed at CIAM for investigatory study on a test bench are shown. Test facilities for experimental investigations of TRE in 'connected tube' manner and experimental work technology features are presented. Some results of the CIAM TRE experimental study included engine parameters on changing to ramjet operation mode variation. Working parameters in the windmilling (ramjet) mode of operation, and flow characteristics in the afterburner-ramjet combustion chamber are shown. A TRE based on TF parts characteristics matching on changing to ramjet operation mode and engine working parameter variations when going to windmilling in the ramjet mode are discussed. This report provides a guide for the measurement of transient aerothermodynamic performance parameters of aircraft gas turbine engines or components for engine developers, test agencies, certifying authorities, and operators of overhaul facilities and aircraft. It may be treated as an extension of AGARD Advisory Reports AR-245 and AR-248. It includes discussion of recommended procedures for the transient measurement of pressures, temperatures, flows, component geometry including rotational speed and clearances, thrust, torque, and the use of the engine control system for transient parameter measures. Typical examples are presented. A section on data acquisition and processing is included. Higher frequency dynamic measurements are excluded. Two examples, the measurement of compressor ratio and air flow at surge and a measurement of engine acceleration time are discussed in detail. This Advisory Report was prepared at the request of the Propulsion and Energetics Panel of AGARD. Author

This paper reviews the requirements of the United Kingdom Armed Services for helicopter engines and the technology

developments that will be necessary to meet these requirements. The work that is being done in the UK to ensure that this technology is demonstrated in a timely manner is also examined. Reductions in defense budgets will have a considerable effect on the requirements, and the paper also addresses the effect such reductions will have on future technology. Whilst there continues to be a divergence between naval and land-based requirements, overriding importance is now being given by all operators to cost of ownership issues. The need to reduce the cost of ownership will therefore need to influence all the research and technology demonstration programs on which future engines will rely.

In June 1993, the MTR390 has completed all its important certification tests. This marks a major step in the development and qualification program of this engine which was selected to power the new German/French anti-tank, support and attack helicopter, the EUROCOPTER TIGER and GERFAUT. The MTR390 is a new turboshaft engine in the 1000KW (1300shp) range being jointly developed by three of the largest European aero engine companies: MTU in Germany, TURBOMECA in France, and ROLLS-ROYCE in Great Britain. The joint company MTR GmbH which is registered in Germany, acts as contractor for the German and French governments. MTR directs and coordinates the development, production, marketing, sales, and customer support of the MTR390 engine for the Franco-German helicopters and other potential applications. The three companies have been working together for more than 25 years on several programs like Adour, Larzac, RB199, EJ200, RTM322,.... The declared goal of the MTR partner companies is to create an engine that will not only suit the TIGER/GERFAUT program but will also compete in the military and civil market for the next 20 to 30 years. The paper describes the aerodynamic and thermal design for the hot-section core engine components, i.e. the combustor and the HP turbine, for an application related to a propulsion system of 1000 kW class. The annular reverse-flow flame-tube is very compact in length and radial dimensions. The high pressure gas-generator turbine is an axial-flow single stage, aerodynamically high loaded, and has nozzle vanes as well as rotor blades cooled by impingement, film cooling and forced enhanced convection techniques. Furthermore the core engine hot section rig has been designed to allow, through an extensive experimental program, the verification of the performances, and to study the impact of the cooling systems on the thermo-mechanical behavior of the components. (AGARD-CP-537) Copyright Avail: CASI HC A01/MF A04

Design and experimental results of a small turboshaft operating with self-heating working fluid are presented here. The working fluid is water steam produced through H2, O2, H2O combustion, water being injected gradually on the H2/O2 stoichiometric combustion products. High pressure (50 divided by 70 bar) and high temperature (1000 divided by 1500 K) water steam is involved, respectively, because of mechanically driven pumps for liquid hydrogen and oxygen and water, and because their combustion. So, water steam is operating the turboshaft until vacuum pressure condenses in an aircondenser after a previous heat exchange, in a closed cycle. Only a part of the steam latent heat is going to the environment. An overall thermodynamic design, and a more detailed combustor design, are presented, showing high cycle efficiency and validity for such a non-polluting turboshaft. Experimental results of the H2/O2/H2O combustor are reported. Applications are suggested for small power entertainment airplanes, rescue helicopters, and non-polluting airport ground vehicles.

Extensive testing was done on a T55-L-712 turboshaft engine compressor in a compressor test rig at TEXTRON/Lycoming. These rig tests will be followed by a series of engine tests to occur at the NASA Lewis Research Center beginning in the last quarter of 1993. The goals of the rig testing were: (1) map the steady state compressor operation from 20 percent to 100 percent design speed, (2) quantify the effects of compressor bleed on the operation of the compressor, and (3) explore and measure the operation of the compressor in the flow ranges 'beyond' the normal compressor stall line. Instrumentation consisted of 497 steady state pressure sensors, 153 temperature sensors and 34 high response transducers for transient analysis in the pre- and post-stall operating regime. These measurements allow for generation of detailed stage characteristics as well as overall mapping. Transient data is being analyzed for the existence of modal disturbances at the front face of the compression system ('stall precursors'). This paper presents some preliminary results of the ongoing analysis and a description of the current and future program plans. It will primarily address the unsteady events at the front face of the compression system that occur as the system transitions from steady state to unsteady (stall/surge) operation. Author

New materials and component technologies are undergoing feasibility assessment in expendable gas turbine demonstrator engines. The new technologies, developed under the Integrated High Performance Turbine Engine Technologies (IHPTET) and other initiatives, address the need for improved engine performance, lower cost, and lighter weight. Engine and rig tests conducted on high temperature composite turbine components, fuel-lubricated ceramic bearings, low cost, light weight organic composite structures, and a novel low cost cooled turbine rotor concept are described in this paper. Also, additional development requirements for transitioning these technologies to production applications are defined. Author

The T117 Turbojet Engine (formerly KHD T117) is a single shaft light weight turbojet of the 1000 N thrust class. It was especially developed to fit into the reconnaissance drone Canadair CL 289. The demand for smallest possible size of the compressor to fit the constraints of outer diameter and axial length of the complete engine showed early that only a single stage radial compressor would be applicable. The compression system of this turbojet is described in some detail. The performance maps of the compressor at the test-stand without and with turbojet inlet system are shown. Calculated and measured operating lines in the performance maps show good agreement. Tests with several production engines to establish the compressor performance map are shown and they confirm the compressor map with turbojet

inlet system at the compressor test-stand. Enough surge margin for the jet-engine is demonstrated. Investigations with curve flight simulation show a stable performance of the jet engine. Author

ADVANCED CONCEPTS FOR NEXT GENERATION SMALL GAS TURBINE ENGINE COMPRESSORS

ARUN K. SEHRA and HOWARD F. MERRICK *In* AGARD, Technology Requirements for Small Gas Turbines 7 p (SEE N94-34431 10-07) Mar. 1994

(AGARD-CP-537) Copyright Avail: CASI HC A02/MF A04

The trend in advanced gas turbine engines is towards lightweight, high performance, compact, reliable compression systems. This has created a need for a compression system capable of delivering extremely high stage pressure ratios. Textron Lycoming is currently developing multistage axial compressors with average pressure ratios in excess of 2.5 and single axial stages capable of delivering pressure ratios in excess of 3.5. Major advances in the aerodynamic design techniques and material/structural technologies are necessary to achieve the performance and weight objectives of these compression systems. This paper describes some of the recent advances made in the aero design concepts (swept shock rotors, splittered rotors), computational fluid mechanics, active stabilization system, and material/structural innovations (metal matrix composite titanium aluminide impellers) to meet the challenge of the next generation of gas turbine compression systems. ADVANCED SMALL HIGH PRESSURE RATIO CENTRIFUGAL COMPRESSOR

M. H. KALOGIANNIS, A. D. LEBLANC, and S. M. PRZYBYTKOWSKI *In* AGARD, Technology Requirements for Small Gas Turbines 6 p (SEE N94-34431 10-07) Mar. 1994

(AGARD-CP-537) Copyright Avail: CASI HC A02/MF A04

This paper describes the design approach for a high pressure ratio, single-stage, centrifugal compressor that meets current small helicopter engine performance requirements. Test results are provided for a 10:1 pressure ratio single-stage having 80 percent efficiency and 27 percent surge margin. Development of three dimensional computational fluid dynamics has generated the tools to design impellers with improved surge margin while maintaining state of the art efficiency. Further development of Euler and Navier-Stokes codes is required to analytically optimize the impeller-diffuser match and to improve efficiency levels. Author (revised)

THE CENTRIFUGAL COMPRESSOR, AN ESSENTIAL COMPONENT OF SMALL AND MEDIUM POWER ENGINES [LE COMPRESSEUR CENTRIFUGE, COMPOSANT ESSENTIEL DES TURBOMOTEURS DE PETITE ET MOYENNE PUISSANCE]

P. BELAYGUE and H. VIGNAU *In* AGARD, Technology Requirements for Small Gas Turbines 15 p (SEE N94-34431 10-07) Mar. 1994 In FRENCH Original contains color illustrations

(AGARD-CP-537) Copyright Avail: CASI HC A03/MF A04

Originally, the centrifugal compressor formed the basis of the first aeronautical applications of turboshaft engines. Recently, it has been almost exclusively used behind axial compressors as the last compression stage in turbines of small and medium power, with a moderate pressure ratio. As a result of numerous studies which have been carried out during the last two decades, it has been elevated to a key position. Thanks to the progress in the field of analytical tools (concerning aerodynamics, structures, and heat transfer), materials, and processes, its characteristics are such that, besides its traditional use as the last compression stage, it can also perform the following functions: (1) form the only compression stage (up to a compression ratio of 12); and (2) be combined with another centrifugal stage to reach an overall pressure ratio of 20 without using variable geometry. Because of the great simplicity ot the assembly, its intrinsic performance (efficiency, pressure ratio, surge margin, low sensitivity to clearances, and distortions) as well as its ease of integration, it is considered as an essential component to be used in an helicopter engine, the requirements of which can be classified as follows: high specific power, very good reliability, low cost, and performance compromise--cruise specific consumption, emergency power, and response time in transient condition. Its present capacity to run with higher specific flows and the use of variable geometry open new doors to other applications: jet engines and auxiliary power units. Author (revised)

An experimental and computational investigation of the NASA Low-Speed Centrifugal Compressor (LSCC) flow field was conducted using laser anemometry and Dawes' 3D viscous code. The experimental configuration consists of a back-swept impeller followed by a vaneless diffuser. Measurements of the three-dimensional velocity field were acquired at several measurement planes through the compressor. The measurements describe both the throughflow and secondary velocity field along each measurement plane and, in several cases, provide details of the flow within the blade boundary layers. The experimental and computational results provide a clear understanding of the development of the throughflow momentum wake which is characteristic of centrifugal compressors. Author (revised)

Smaller, smarter, airbreathing propelled tactical missiles are being proposed and developed. They will function for various military duties currently performed by larger, limited range missiles or manned surveillance and interdiction aircraft. The extreme compactness of these missiles requires relatively high power density small turbojets. The missile air inlet location and configuration in many of these applications may impose highly distorted compressor inlet flow conditions, with potentially deleterious effects upon compressor performance, both in terms of flow range stability and compression efficiency. Renewed interest has therefore been focused upon alternative compressor design solutions with improved stability, more tolerant to flow distortion effects. In this respect, splitting the compression diffusion process into multirow or tandem cascades has been proposed as a means of attaining increased flow range and efficiency, both in axial and centrifugal compressors. Centrifugal compressors are popular for small, low cost, expendable missiles, especially with compact diffusers permitting reduced frontal area. An experimental study of the effect of a tandem radial cascade diffuser configuration on the performance of a small, high specific speed transonic centrifugal compressor stage is described in this paper. Tests showed the importance of the first tandem row on overall compressor performance and demonstrated higher flow range at the expense of slightly reduced efficiency, as compared to an optimum channel type diffuser. To enhance fuel efficiency, future advanced small gas turbine engines will utilize engine cycles calling for overall engine pressure ratios, leading to higher combustor inlet pressures and temperatures. Further, the temperature rise through the combustor and the corresponding exit temperature are also expected to increase. This report describes future combustor technology needs for small gas turbine engines. New fuel injectors with large turndown ratios which produce uniform circumferential and radial temperature patterns will be required. Uniform burning will be of greater importance because hot gas temperatures will approach turbine material limits. The higher combustion temperatures and increased radiation at high pressures will put a greater heat load on the combustor liners. At the same time, less cooling air will be available as more of the air will be used for combustion. Thus, improved cooling concepts and/or materials requiring little or no direct cooling will be required. Although presently there are no requirements for emissions levels from small gas turbine engines, regulation is anticipated in the near future. This will require the development of low emission combustors. In particular, nitrogen oxides will increase substantially if new technologies limiting their formation are not evolved and implemented. For example, staged combustion employing lean, premixed/prevaporized, lean direct injection, or rich burn-quick quench-lean burn concepts could replace conventional single stage combustors. Due to combustor size considerations, staged combustion is more easily accommodated in large engines. The inclusion of staged combustion in small engines will pose greater combustor design challenges. Author

A review of aircraft gas turbine engine performance trends indicates that the smaller the engine the lower are its cycle pressure ratios, which suggests the less the combustor design challenge. This is often reflected in projected development effort. In fact, many aspects of combustor design and performance are adversely affected in smaller engines. Furthermore, when emission reduction requirements are extended to smaller engines, the design comprises needed to meet all performance goals will become particularly acute, and design solutions from large combustors may not be applicable. This paper addresses small aircraft gas turbine emissions from the viewpoints of environmental impact and control technologies. Improvements achieved in small engine emissions without regulatory control are highlighted, as well as limitations on applicability of 'large-engine' technologies due to scale constraints and the highly cost-sensitive small engine market. This paper discusses CFD applications to the analysis and optimization of the temperature distribution factor (TDF) in small, high intensity complex flow field gas turbine combustors. TDF is a term used to describe the nonuniformity of the temperature profile in the combustor exit plane which results from the inability to fully mix out temperature peaks. Hot end durability will be locally affected by temperature peaks whereas total energy exchange is dependent on the gas path bulk average temperature rise. Control of the TDF thus allows increased overall efficiency from both the cycle temperature and cooling load perspective while minimizing hot end distress. Computational fluid dynamic analysis of three dimensional combustor flows and the empirical validation of results are used to demonstrate the effectiveness of CFD as a design tool in this challenging environment. High specific power and a small SFC are major objectives in the development of advanced turbo shaft engines. The reduced number of turbine stages leads to a considerable increase of their aerodynamic loading. The design and development of a transonic single stage turbine for a pressure ratio Pi equals 3.6 was carried out at MTU in a technology and demonstration program. Results of the extensive annular cascade, cold flow rig, and gas generator engine testing are presented including detailed investigations of transonic vane and blade flow fields, stator/rotor matching effects, and the influence of film cooling flow and tip clearance variations on the turbine performance. The efficiency level of turbine stages with small blade height is mainly determined by the endwall losses because they are significantly higher than the profile losses. In spite of extensive research work in this field, there are still some unsatisfactorily solved problems. The paper deals with two problems: the increase of the endwall losses downstream the cascade and the influence of the cascade inlet boundary layer thickness on the endwall losses. Because the inlet boundary layer is twisted mainly by the tip clearance vortex of the cascade upstream, the effect of a skewed inlet boundary layer is shown as well. Finally, measurement results of a turbine stage with blade height L equals 30 mm (D(sub m)/L equals 13) are shown for the cases with and without shroud. Author (revised)

This paper describes the performance of a highly loaded turbine stage with a pressure ratio of 3.75 and a stage loading of 2.47. Tests were carried out with two rotor blade counts at design and 70 percent speeds for a range of tip clearances from 1.1 to 2.1 percent of blade span. The results are presented in the form of radial distribution of stage exit swirl and efficiency and are compared with the prediction of a 3-D Euler flow solver. The measured efficiency drop for a 1 percent change in tip clearance is 2.6 and 1.1 percentage points at 100 and 70 percent speed, respectively. The efficiency drop reduced from 2.6 to 1.7 percentage points with a 33 percent reduction in blade count. The effect of clearance variation on stage exit conditions was seen to extend over most of the blade span. Author

As axial and radial turbine designs have been pushed to their aerothermodynamic and mechanical limits, the mixed-flow turbine (MFT) concept has been projected to offer performance and durability improvements, especially when ceramic materials are considered. The objective of this NASA/U.S. Army sponsored mixed-flow turbine (AMFT) program was to determine the level of performance attainable with MFT technology within the mechanical constraints of 1997 projected ceramic material properties. The MFT geometry is similar to a radial turbine, exhibiting a large radius change from inlet to exit, but differing in that the inlet flowpath is not purely radial, nor axial, but mixed; it is the inlet geometry that gives rise to the name 'mixed-flow'. The 'mixed' orientation of the turbine inlet offers several advantages over radial designs by allowing a nonzero inlet blade angle yet maintaining radial-element blades. The oblique inlet not only improves the particle-impact survivability of the design, but improves the aerodynamic performance by reducing the incidence at the blade inlet. The difficulty, however, of using mixed-flow geometry lies in the scarcity of detailed data and documented design experience. This paper reports the design of a MFT stage designed with the intent to maximize aerodynamic performance by optimizing design parameters such as stage reaction, rotor incidence, flowpath shape, blade shape, vane geometry, and airfoil counts using 2-D, 3-D inviscid, and 3-D viscous computational fluid dynamics code. The aerodynamic optimization was accomplished while maintaining mechanical integrity with respect to vibration and stress levels in the rotor. A full-scale cold-flow rig test was performed with metallic hardware fabricated to the specifications of the hot ceramic geometry to evaluate the stage performance. Author

Radial inflow turbines have various applications in industry and are being used as major components of gas turbines and turbochargers. The details of the flow phenomena within these machines are ill-define especially in small high speed units where small passages and high velocities are involved. To gain a better understanding of these flow processes, a small radial inflow turbine has been studied using laser anemometry. The main area of interest has been the region between the nozzle guide vanes and the turbine rotor. The flow in this region has been investigated at several positions across the nozzle guide vane pitch and span. The influence of the passing blades on the guide vane flow has also been studied. The results obtained have been compared with those from a previously studied (comparative) unit. The flow phenomena from the two machines differ quite markedly in the extent of the distortion observed at the nozzle guide vane and rotor interface. Author

A number of different factors drive and constrain the development of future technology. This paper looks at the current perspective on the development of agile aircraft systems and more specifically, the engine characteristics these demand. Having identified the desirable engine characteristics, the key technologies required to enable them are discussed. It is proposed that the optimum agile aircraft system will be achieved given these technologies by considering the best way in which the engine should be 'rated' to fulfill the operational requirements envisaged. The NATO requirement for increased range and endurance of aircraft is also associated with the necessity to reduce the initial and life cycle costs of these aircraft. Consideration of these conflicting requirements leads to the prioritization of engine technologies for different vehicle types and presented here are views of engine manufacturers addressing these challenges over the range of aircraft. This paper will discuss the prioritization of technologies required for the range of air vehicles and examine how increases in endurance and range affect the balance of technology within each propulsion unit type. It is convenient to group the vehicles in the following way: transport, tanker, AWACS; maritime patrol; combat; and special purpose. Each grouping has the challenges of range or duration subject to its class, although clearly in absolute terms the range of transport vehicles is significantly different from that of a combat aircraft. It is primarily these differences in the groupings that give rise to the differences in technology prioritization. Derived from text

This Lecture Series will present and discuss the scientific problems of modern mathematical simulation of gas turbine engines and their components. Some peculiarities of complex multicomponent and multidisciplinary models for whole flow passage of bypass gas turbine engine, core, multistage compressors and turbines, and other engine components will be studied. Solutions of steady and unsteady problems are given using high efficiency monotone numerical methods and the theoretical bases of these methods are presented. Many practical results of aerodynamic and thermostress simulations for engine components are shown. These results are compared widely with experimental data for accurate verification of developing computational codes. This Lecture Series, endorsed by the Propulsion and Energetics Panel of AGARD, has been implemented by the Technology Cooperation Program. For individual titles, see N95-19018 through N95-19026.

Mathematical models for gas turbine engines and installation component flow passages based on real 3D geometry of flow passages, in particular spatial shape of blades, are considered. The models are based on numerical solving of unsteady Euler equations and so it allows simulation of some unsteady transitional functioning regimes of engines and installations together with steady ones. The models take into consideration the viscous losses, leakage in axial gaps and tip clearances, cooling air injection and selection. The first level mathematical models are based on 2D steady and unsteady methods on S(sub 1) and S(sub 2) surfaces. Some features of numerical algorithms based on these methods are considered. The second level models are based on 3D approaches anywhere in computational domains excluding the middles of axial gaps between neighboring blade rows where for the simplification of the problem the averaging in angular direction is fulfilled. Numerical models for the thermostress state analysis of turbine rotor elements are discussed. Steady and unsteady temperature fields are calculated and result in solution of conjugate heat and hydraulic problems for blades (quasi three-dimensional model) for disk (two-dimensional model) and for the whole cooled rotor (three-dimensional model). A lot of attention is given to mass flow calculation in blade passages and turbine circumferential disk cavities. They are determined by using experimental data for pressure loss and generalized dependencies for friction and heat transfer coefficients on stators and rotors surfaces. On external blade surfaces the boundary conditions are defined from the solution of two-dimensional and three-dimensional gas dynamics problems and corrected from experimental data base for film cooling. The thermostress state is calculated by a finite element method for realistic geometry using common equations of elasticity theory. Author

Accurate prediction of the temperature distribution in rotating blades is an important and difficult task. An approach for the verification of hydraulic and thermal models in real blades is discussed in the lecture. For static conditions, predicted local internal convective heat transfer coefficients on blades are corrected using a quasi-3D thermal-hydraulic model with the blade unsteady surface temperatures measured by the Thermovision system. External boundary conditions are corrected using the blade base surface temperatures measured by thermocouples on a hot static rig. The final identification of the models is carried out using measurements of the gas temperature distribution within the rotating blade passage, and the measured blade external surface temperature in the engine. The Turbo Union RB 199 engine was developed during the late 1960's / early 1970's to meet a specification requirement aimed at defense of the Western European NATO alliance countries against the (then) perceived threat. During the latter part of the 1980's Tornado aircraft were delivered to the Royal Saudi Air Force and, supplemented by deployed units from the Royal Air

Force, were engaged in an operational role during 1990 / 1991. Aircraft operations in the Saudi Arabia climates and natural environment created problems with engine life, hitherto not encountered in the European area of operation, nor during many RAF overseas deployments, including North America. These problems, mainly concerned with turbine blade contamination from airborne sand, were alleviated by the introduction of unique engine maintenance management techniques and eliminated by design changes. During the initial phase of the Gulf Crisis, the principal instrument at the disposal of the British Government which could respond in time was air power. This situation continued, and throughout the period of military build up and subsequent conflict air power remained a dominant factor. During the period, many equipment modifications were incorporated to increase both performance and reliability, and the gas turbine engines which powered the RAF's aircraft were no exception. However in some cases, engines were operated at a much increased flying rate in harsh operating conditions in standard configuration. This paper reviews the operating experiences and some of the modifications incorporated, including the subsequent effect on aero-engine reliability trends. Author

The impact of operating in a sand and dust environment on U.S. Army rotorcraft turbine engines has been a major concern since the first turbine powered UH-1 Iroquois (Huey) helicopter was fielded in the early 1960s. The implication on turbine engine performance and durability had not sufficiently been recognized, or addressed, in early engine designs. Early engine military specifications had been primarily concerned with U.S. Air Force 'jet' engines for fixed wing aircraft. Although these early specifications included sand and dust requirements relative to ingestion capability and test substantiation, actual rotorcraft field experience was not considered, nor, in fact, was actual data available. This paper provides a brief history of the impact of operation in sand and dust and operational considerations on U.S. Army rotorcraft turbine engines. The general effects of sand and dust erosion, compaction, deformation, glassing, etc., on engine turbomachinery will be discussed. Finally, the results of operation in Southeast Asia, and during Desert Shield/Desert Storm, possibly the worse case operational environment encountered to date, will be presented. Author

Recent events have highlighted the fact that none of the currently available turboshaft intake protection systems, whether they be the permanent fit IPS or mission specific vortex pack types, have an adequate sand/dust separation capability. Evidence has been amply provided by low engine life, consequent support logistics problems and the necessity for development of short term emergency measures. The paper seeks to quantify the extent of the problem and define the solutions which will be required if a repeat of past experiences is to be avoided. The paper describes the directions which particles separator technology must take in order to meet future requirements. A further important aspect of future directions is the drive for an increase in an engine's ability to resist damage; the paper identifies those areas of the engine which are most prone to damage, comments on the need to strike the right balance between resistance and removal, and discusses the increasing value of sophisticated computer based design methodologies. Foreign Object Damage (FOD), Domestic Object Damage (DOD), bird ingestion, and ice ingestion are all necessary factors to be considered in the design of reliable and maintainable fan systems for future U.S. Navy aircraft applications. The high rate of fan damage reported in U.S. Navy engines and its impact on repair and maintenance requirements such as engine down time, level of repair, and number of spares have caused the Navy in recent years to scrutinize the requirements which must be met in order to design a more reliable and rugged yet highly maintainable fan system for future aircraft. This paper reports the results of an investigation into the occurrences of Foreign Object Damage in several U.S. Navy aircraft, the repair approaches presently used by the U.S. Navy, and investigates the implications which these considerations present to the design of more damage tolerant fan systems. It further investigates the trade-offs in future turbomachinery design which balance gas turbine engine performance payoff against supportability and maintainability onboard ship. Author

Modern propulsion engines have achieved a high level of reliability while manufacturers and users are always striving to further improve the safety record. The drive for safety in single-engine aircraft has resulted in safer multiple-engine applications. In modern turbofan-powered transports it is extremely unlikely that a failure intrinsic to an engine would initiate a sequence of events which could result in loss of capability for continued safe flight and landing. These rare events are limited to uncontained rotor disk fracture or uncontrolled fire. Of greater concern today are the non-intrinsic, common-cause events which involve power loss of more than one engine. These are externally-inflicted occurrences such as ingestion events or common-cause maintenance events resulting in simultaneous loss of power on more than one engine. The most frequent are those ingestion events involving products of the flying environment - flocking birds, ice, volcanic ash and extreme inclement weather. This environmental ingestion hazard viewed in overview is the primary

subject of this paper. There is a body of knowledge on each of these subjects. Data from field operations and engine experience have provided guidelines for recognition of an occurrence and the proper action response. The primary precaution however remains - be aware, prevent, communicate and avoid. Author

The aerodynamic processes leading to film cooling hole blockage have been investigated experimentally in large scale models of idealized internal cooling passages. The experimental scaling included reproducing engine cooling passage and hole Reynolds numbers together with a new dimensionless group which was matched experimentally to ensure that the measured particle trajectories were engine representative. It has been possible to achieve correct dimensional scaling with particles one thousand times larger than engine size. Simple visualization of the particle trajectories showed concentrations of impact locations inside holes normal to and inclined to the cooling passage surface. No attempt was made to model interaction between the particles and the passage walls. A new instrument has been developed to measure the concentration of particle impacts. Use of the device provides a fast and convenient way of measuring particle impact distributions. The regions of high impact concentration are consistent with blockage structures found in engines after service. The process of internal blockage of film cooling holes has been shown to be due to inertia driven particles of the order of 1 micron in diameter. Flow conditions immune from impact concentration and hence the blockage process have been identified for the inclined film cooling hole. Author

Particles ingested in gas turbine engines follow trajectories that generally deviate from the flow streamlines and impact the component surfaces causing erosion damage. This paper deals with the experimental and numerical simulations of particle dynamics including surface interactions and the associated blade erosion in gas turbine engines. The experimental studies of particle surface impacts include the nonintrusive measurements of particle bounce conditions and the erosion testing of blade materials and blade coatings. Data obtained in the University of Cincinnati's high temperature erosion test facility at temperatures up to 1500 F for different alloys and coatings are presented. The numerical studies to simulate the particle dynamics in the turbomachines are described. Results of combined experimental and computational modeling are presented for the particle dynamics, the associated turbomachinery blade erosion, and performance loss. The probabilistic modeling of the experimentally measured variance in the particle bounce conditions and the loss of performance associated with particle ingestion are discussed. Author

This paper describes the technique of particle trajectory modeling in gas turbine engines with applications in helicopter inertial particle separator, axial ad centrifugal compressor. The model can be used with most CFD codes which utilize the finite volume (or element) techniques. Some qualitative validations were carried out using a laser transit anemometer in a particle separator and results show good comparison with predictions. The anemometer was also used to obtain restitution data for several target materials using quartz particle of different sizes at a range of impact velocities and angles. Author

Erosion of the turbomachinery and other components in helicopter gas turbines operating in a sandy environment is a significant problem. In order to better understand the mechanics of such erosion, and to enable the design of components better able to withstand it, a means of modelling erosion is needed. Such a method has been developed at Turbomeca. It consists of a method of predicting the trajectories of the particles within the component, on the basis of a prescribed aerodynamic field and taking into account rebounds from the walls, together with correlations for the erosion caused by impacts of the particles with the walls. The various aspects of the method have been validated by comparison with available experimental data and these comparisons are presented. Predictions of particle trajectories in two types of particle separator and in two gas turbine compressors (axial and centrifugal) are also presented, together with some comparisons with experiment. During flight operation the engine swallows sand or other hard particles usually from the runway. Passing through the compressors they will damage the blades, erode the coating and deteriorate seals. The submitted paper presents some measurements, which show the effect on compressor performance due to the most important and frequent defects. The investigation - conducted at high pressure compressors - includes tests with reworked blades at leading and trailing edges, rounded rotor tips and increased tip clearances. The results are summarized in easy to handle correlations, which enables the user to estimate the deterioration and to fix repair rules within the allowed performance loss range. Author

Severe trailing edge erosion of ALLISON T56 gas turbine 5th and 10th stage compressor blades has been observed in Field Service Evaluations and sand ingestion tests. The erosion typically occurs within 3 mm of the blade tip and has been attributed to overtip flow produced by the bleed holes present over the 5th and 10th stage rotors. The overtip flow through the 5th stage bleed holes of an operating T56 has been surveyed with a laser two-focus (L2F) velocimeter in order to identify the features of the flow field responsible for the tip erosion. Two-dimensional measurements were made at 4 spanwise locations in the outer 25 percent of the span. Three-dimensional measurements were made at three spanwise stations within 7 mm of the blade tip (15 percent of span). The flow was found to be unaffected by the bleed holes beyond 3-4 mm from the blade tip. This result is consistent with erosion patterns observed on service-exposed

blades and blades subjected to accelerated erosion in sand ingestion tests. Author

FOD and erosion are the events causing the most part of accidental damages in gas turbine engines. When FOD is not destroying or when erosion is in progress the performance level decreases and the necessity of unscheduled maintenance actions becomes quite real. Moreover when there is a light FOD, or the erosion process is constant in time, it may be difficult to detect the exact cause of performance decrease and to plan the most effective maintenance action. This paper deals with the results of a study carried out for developing an Engine Condition Monitoring system particularly suitable for detecting the MicroFOD and erosion effects in gas turbines. The developed numerical code has been applied to a single spool turboshaft engine with free power turbine. The obtained results are presented and discussed. Author

The quality of fan blades in terms of behavior is one of the major parameters affecting the safety of modern aircraft driven by engines with strong by-pass ratio. The reinforcements defined as necessary in certain areas of the profiles of the fan blades must be a compromise between the objectives of mechanical resistance and aerodynamic performance. SNECMA developed a methodology to forecast the impact behavior of the fan blades based on a mathematical model. In parallel, the progress made in aerodynamics made it possible to predict the consequences of these stresses related to ingestion on aerodynamic performance and still maintain high levels of performance. Impacts of 1 inch diameter ice bullets onto stator vanes of the first stage of an axial compressor were investigated at an impact velocity of v = 257 m/s. The analytical and experimental simulations of typical hailstone ingestions were performed with special emphasis on damage effects of the thin leading edges of the hidden titanium vanes. The paper includes a comprehensive overview of the ice properties used in the analytical model regarding elastic constants, strain rate dependent strength and crack propagation under compression. The influence of different impact positions and ice properties was investigated in the analytical simulations. In all cases the highest stresses occur at the leading edge of the hidden vane. When the center of impact is placed on the leading edge plastic deformations are expected and localized microcracks cannot be excluded. When the target point is positioned on the suction side of the vane (air foil flank) the energy transfer and the loading is high, but the deformations remain elastic. For verification shooting tests of ice bullets on a complete stator were performed. The ice balls were made by freezing water in liquid nitrogen and the impacts were recorded with a high speed camera. The observed leading edge deflections are in good agreement with the calculated values, but in no case plastic deformations or cracks were detected. Author

The strength of titanium fan blades under soft body impact has been studied by means of panel tests. The panels, representing blades with various leading edge profiles, were exposed to oblique impact in a gas gun facility by launching a block of gelatine at speeds of up to 600 m/s. High speed photography, at 100,000 f.p.s. and strain gauges provide a record of the deformation. Failure occurred either as a result of the deformation or localized tearing. Tearing was taken as determining the limiting strength of the blade, which was found to be strongly dependent on the leading edge profile. Author

A computational capability is described for evaluating the ice-impact on engine blades made from composites. The ice block is modeled as an equivalent spherical object and has the velocity opposite to that of the aircraft with direction parallel to the engine axis. A finer finite element mesh is used for a portion of the blade near the impact region compared to the course mesh for the rest of the blade. The effects of ice size and velocity on the average leading edge strain are evaluated for a simulated unswept composite propfan blade. Parametric studies are performed to assess the blade structural responses due to the ice-impact at various locations along the span. It is found that: (1) for a given engine speed, a critical ice speed exists that corresponds to the maximum strain; and (2) the tip bending type frequencies increase after impact while the torsion frequencies decrease. The blades and vanes in gas turbine compressors operating in dusty environments are prone to degradation by solid particle erosion, which causes surface roughening and changes in airfoil geometry. This results in decreased compressor performance, and higher specific fuel consumption, leading to significantly increased operational cost. Erosion damage is more prominent in flight engines without air inlet filter protection. Application of a thin ceramic titanium nitride (TiN) coating to improve the erosion

resistance of compressor airfoils was thoroughly investigated. Coatings were applied to engine hardware by a Reactive Ion Coating (RIC) process and optimized to produce a very adherent erosion resistant coating. Computer modeling of the erosion process occurring on coated and uncoated airfoils suggested that the operational life of the compressor can be enhanced by a factor of two. A complete set of compressor blades and vanes for an Allison T56 turboprop engine was coated for engine qualification tests. Laboratory tests showed that the thin coating had no significant influence on either the resonant frequency or the fatigue resistance of the blades and the instrumented engine tests confirmed that the performance was typical of overhauled engines, with no aerothermodynamic loss. Therefore, titanium nitride coatings are suitable for service and can be used on existing engines to improve the life of the compressors. Author

Turbine engines for aeronautic applications now have to face strenuous requirements concerning not only operating performances but also reliability and repairability. This evolution of the specifications induces important consequences regarding the choice and the design of turbine blade protective coatings. This paper presents several key features concerning the deposition techniques and the real-life behavior of such coatings: (1) complex aluminides well suited to the protection against high temperature oxidation and hot corrosion of directionally solidified nickel-base superalloy turbine blades; (2) ceramic coatings used as thermal barriers - they have to exhibit both high resistance to thermomechanical fatigue and adequate smoothness; (3) processing techniques for thermal barriers, including plasma spraying, electron beam physical vapor deposition and plasma enhanced chemical vapor deposition; and (4) blades and coatings repair techniques. Overlay braze repair is a good technique for restoring aircraft vanes and industrial blades and vanes. The negative effects of the intermetallic phase, formed during the overlay braze process, can be reduced in such a way that the mechanical properties - creep rupture, strength and ductility - can be achieved close to the properties of the base materials. The elimination of the negative effects can be achieved by a combination of careful selection of the chemistries of the repair materials and the application of the correct procedures for cleaning and heat cycle. It is shown that for gas turbines in the West European environment: (1) during operation hygroscopic salts - notably ammonium sulphate (originating from manure) and sodium and magnesium chloride (from sea salt) - are deposited on compressor components and (2) during shutdowns these wet deposits acidify owing to the absorption of the air pollutants NO2 and SO2. The response of the compressor metals can be broadly categorized as follows. Different steels show different degrees of corrosion. Especially pitting corrosion can lead to component rejection and compressor disintegration. This necessitates frequent washing and/or corrosion resistant coatings. Modern cleaners are environmentally friendly and contain a corrosion inhibitor. The performance of cleaners and coatings is discussed. Nickel-based superalloys and titanium alloys are not prone to corrosion in compressor applications. In order to avoid problems these materials should be used even for secondary components. This is exemplified by a crash due to stress corrosion of a component costing only a few dollars. Compressor erosion as such is not a major problem in Western Europe. However, corrosion resistant coatings usually have a poor erosion resistance. Moreover, engine manufacturers and users prefer a general compressor coating for use in both corrosive and erosive environments. Developments with respect to compressor cleaners and coatings are discussed. Author

Gas turbines for helicopters are prone to high degradations by abrasive particle ingestion when taking off, landing or during low altitude flights. Multilayer coatings have been developed to protect critical compressor components. After a presentation of the relevant parameters for conception and achievement of erosion resistant coatings, the most promising systems will be described. They are based on stacking arrangement of ductile layers (tungstene) and hard layers (solid solution of carbon or nitrogen into tungstene, titanium diboride). These multilayer coatings exhibit an erosion resistance improved by more than two orders of magnitude compared with that of uncoated Ti6Al4V alloy. Author

High velocity oxygen fuel (HVOF) spraying is the most recent development in the field of thermal spraying. The importance of this technique for the repair and new part manufacturing of jet engine parts is rapidly increasing. The HVOF uses a supersonic oxygen-fuel flame to heat and accelerate the powder particles that form the coating. The high particle velocity results in a high density and a low porosity, a high bond strength, and a high macro and micro hardness of the coating. The high quality of the HVOF coatings makes it possible to use these coatings on high loaded, rotating parts in jet engines. This paper will highlight the use of HVOF processes to apply erosion resistant cermet coatings to high pressure compressor blades. These blades are exposed to severe erosion. Next to the D-gun process, HVOF spraying is the only nonproprietary technique that can be used to apply these high performance coatings. Also the use of the HVOF process to apply wear resistant coatings and superalloys to jet engine parts will be discussed. The difference between HVOF coatings and plasma sprayed coatings will be highlighted. During HVOF spraying, the parts are exposed to a high heat flow. Solutions to avoid overheating, especially of titanium parts, will be presented.

A 350 micron thick 7 wt percent Y2O3-ZrO2 (7YSZ) ceramic Thermal Barrier Coating (TBC) was manufactured in an argon atmosphere and with a strictly controlled substrate temperature

on flat IN 600 samples and on IN 100 aircraft turbine blades. This new atmosphere and temperature controlled spraying (ATCS) allows the reduction of the residual stresses and an improvement in the microstructure and in the mechanical properties of the coating. The good performance of these new TBC's was assessed in thermal fatigue and in thermal shock tests carried out in air at 1100 C and at 1280 C respectively. The oxidation rate of the metal-ceramic interface was measured at 1100 C. Failure of the TBC's was induced only by the deterioration (like oxidation, cracking) of the uncoated parts of the samples, as testing temperature was too severe for the base metals. Spalling was thereafter driven by compressive stresses near the aluminum oxide layer at the metal-ceramic interface. The results of these tests underline the good quality of the ceramic coating manufactured by the new ATCS technology. Author

RESISTANCE OF SILICON NITRIDE TURBINE COMPONENTS TO EROSION AND HOT CORROSION/OXIDATION ATTACK

THOMAS E. STRANGMEN (Garrett Turbine Engine Co., Phoenix, AZ.) and DENNIS S. FOX *In* AGARD, Erosion, Corrosion and Foreign Object Damage Effects in Gas Turbines 11 p (SEE N95-19653 05-07) Nov. 1994

(AGARD-CP-558) Copyright Avail: CASI HC A03/MF A03

Silicon nitride turbine components are under intensive development by AlliedSignal to enable a new generation of higher power density auxiliary power systems. In order to be viable in the intended applications, silicon nitride turbine airfoils must be designed for survival in aggressive oxidizing combustion gas environments. Erosive and corrosive damage to ceramic airfoils from ingested sand and sea salt must be avoided. Recent engine test experience demonstrated that NT154 silicon nitride turbine vanes have exceptional resistance to sand erosion, relative to superalloys used in production engines. Similarly, NT154 silicon nitride has excellent resistance to oxidation in the temperature range of interest - up to 1400 C. Hot corrosion attack of superalloy gas turbine components is well documented. While hot corrosion from ingested sea salt will attack silicon nitride substantially less than the superalloys being replaced in initial engine applications, this degradation has the potential to limit component lives in advanced engine applications. Hot corrosion adversely affects the strength of silicon nitride in the 850 to 1300 C range. Since unacceptable reductions in strength must be rapidly identified and avoided, AlliedSignal and the NASA Lewis Research Center have pioneered the development of an environmental life prediction model for silicon nitride turbine components. Strength retention in flexure specimens following 1 to 3300 hour exposures to high temperature oxidation and hot corrosion has been measured and used to calibrate the life prediction model. Predicted component life is dependent upon engine design (stress, temperature, pressure, fuel/air ratio, gas velocity, and inlet air filtration), mission usage (fuel sulfur content, location (salt in air), and times at duty cycle power points), and material parameters. Preliminary analyses indicate that the hot corrosion resistance of NT154 silicon nitride is adequate for AlliedSignal's initial engine applications. Protective coatings and/or inlet air filtration may be required to achieve required ceramic component lives in more aggressive environments. Author

This paper describes the considerations given to the testing of aircraft engines intended for use by the United States military (primarily the Navy) in potentially corrosive environments. The origins and intent of the Navy's full-scale corrosion susceptibility test are explored, and the evolution of the test from its early form to the present 1,200-hour program is described in detail. Sample results illustrating the effectiveness of the current test procedure are presented. Also noted are the activities currently underway to improve the test's effectiveness in the face of advancing engine and test equipment technologies. Author

This paper summarizes ongoing research on the sensitivity analysis of dynamic aeroelastic response of wings. Two approaches are being used to express the unsteady aerodynamic loads: (1) the frequency-domain approach, and (2) the state-space approach. The frequency-domain approach is demonstrated on a three-dimensional box wing and the state-space domain approach is demonstrated on a simple two-dimensional sectional model. Three different methods are used to find the sensitivities: (1) a purely finite difference approach, (2) a semi-analytical approach in which an analytical expression is used for calculating the sensitivity of an eigenvalue of the complex valued aeroelastic matrix, however, the derivatives of the components of the matrix are obtained using finite difference, and (3) a semi-analytic approach that differs from (2) in the sense that the sensitivity of the aerodynamic matrix is now obtained analytically. A good agreement is seen between the three sets of results. For the two-dimensional sectional model the results for the sensitivities of the flutter speed with respect to the various parameters are obtained. Author

The influences of the structural and aerodynamic modeling on flutter analysis and multidisciplinary optimization of fully built-up finite element wing models in an aeroelastic environment are not yet well understood. Therefore, the dynamic aeroelastic and optimization capabilities in the Automated Structural Optimization System (ASTROS) were used to evaluate the flutter behavior and the behavior of structural optimization with flutter constraints of various representative fully built-up finite element wing models in subsonic and supersonic flow. ASTROS was here used as a tool to calculate flutter speeds and frequencies and to minimize the weight of these wing models in subsonic and supersonic flow under given flutter and frequency constraints to determine the effect that these modeling factors have. The main objective of this work is to demonstrate the benefits of interdisciplinary optimization techniques to a modern aircraft design. The optimization is related to a four engine transport aircraft series equipped with a common wing. The series comprises of two aircraft differing in fuselage length by approximately 4 m but with the same maximum takeoff weight. Wing commonality in terms of optimization means that all the significant aeroelastic and static constraints are taken into account in order to achieve a weight optimized but also valid design proposal. In effect, this means that critical flutter situations of both aircraft types dependent on the fuel and load conditions as well as the dimensioning static load cases in combination with the stresses allowable must be introduced into a mathematical optimization model and the weight optimized solution must be sought with the aid of various optimization techniques. NUMERICAL SIMULATION OF SHOCK-STALL FLUTTER OF AN AIRFOIL USING THE NAVIER-STOKES EQUATIONS

K. ISOGAI *In* AGARD, Transonic Unsteady Aerodynamics and Aeroelasticity 12 p (SEE N92-27936 18-02) Mar. 1992

In order to confirm, qualitatively, the unusual flutter phenomenon, which has been observed experimentally for the high aspect ratio (non-tailored) forward swept wing model, as a shock-stall flutter, the aeroelastic response calculation of a two dimensional airfoil whose vibration characteristics are similar to those of the typical section of a forward swept wing, was performed by using the compressible Navier-Stokes equations as a flow solver. By the examination of the flow pattern, pressure distribution and the behavior of the unsteady aerodynamic forces during the diverging oscillation of the airfoil, it is concluded that this is a shock-stall flutter, in which the large scale shock-induced flow separation is playing the dominant role and that there is a mechanism of putting energy into the elastic system of the airfoil, leading to nearly a single degree of freedom flutter. An analysis of steady wind tunnel data obtained for a fighter type aircraft indicated that shock-induced and trailing edge separation plays a dominant role in the development of Limit Cycle Oscillations (LCO) at transonic speeds. On this basis, a semi-empirical LCO prediction method is being developed which makes use of such steady wind tunnel data. The preliminary method was applied to several configurations and correctly identified those which have encountered LCO. The method has the potential for application early in the design process of new aircraft to determine and understand these nonlinear aeroelastic characteristics. The method is still being evaluated, and upgrading and refinements are expected from unsteady wind tunnel force and pressure measurements to be obtained from oscillating models as part of an extensive investigation into the aerodynamic nature of LCO. The method is described in its present form and the results of the latest predictions are compared with flight results and used to further assess various parametric effects. Author

For missiles with cartesian control mode a symmetrical configuration with four inlets is most common. The operation of a multiple inlet system is significantly influenced by the interaction of the coupled inlets. Inherent problems are discussed by means of a simplified model and windtunnel test results. First a configuration with four axisymmetrical inlets is presented. Different inlet geometries and the influence of an external boundary layer bleed are investigated in order to obtain an enlarged stable operation regime. Windtunnel tests of individual inlets and of four coupled inlets showed the effects of inlet matching and the resulting overall performance. Furthermore a configuration with four rectangular inlets is discussed. Problems and advantages of the conventional and the inverted integration mode are illustrated using wind tunnel test results. It is shown that the use of a pre-compression ramp is especially beneficial to the inlet matching of four inverted inlets. Author

IN-FLIGHT STRUCTURAL MODE EXCITATION SYSTEM FOR FLUTTER TESTING

R. B. RAMSAY *In* AGARD, Flight Testing 20 p (SEE N93-19901 06-05) Oct. 1992

(AGARD-CP-519) Copyright Avail: CASI HC A03/MF A04

A system for exciting the modes of vibration of an unstable digitally controlled fly-by-wire combat aircraft via the primary control actuators in order to extract flutter data is presented. The system has been developed on the Experimental Aircraft Program (EAP) to generate, within the Flight Control computers, frequency sweep and impulse excitation signals which are injected via the primary control actuators to the foreplane and wing trailing edge flaperons. The choice of surface, actuator amplitude input and symmetric or antisymmetric excitation is pilot selectable. The system will permit predefined waveforms, referred to as test routines, to be summed into the Flight Control System (FCS) actuation loops under cockpit control. Rig and aircraft ground response performance tests were performed on the foreplane and wing outboard trailing edge flaperon actuators as part of the qualification of the system. A flight test program of 15 flights measured aircraft responses due to the injection of frequency sweeps and impulses. Results are presented for the foreplane and the wing and a comparison made with predictions and previous flight flutter tests using bonker impulsive excitation. Operation of this system demonstrated the flexibility in being able to select the excitation type and input amplitudes, optimized to the aircraft configuration and flight condition, to extract high quality data, which is the key to successful flight flutter testing. Use of this system, particularly where structural limitations restrict the use of other types of excitation, offers great potential in reducing overall testing time for aircraft with a large number of stores, provided the system is designed to have flexibility in the choice of input available to the test engineer. A connected word speech recognizer was mounted in the Flight Research Laboratory's Bell 205 Airborne Simulator (variable stability helicopter) and used to generate direct voice control over the aircraft's trajectory. The purpose of this exercise was to demonstrate the feasibility of sufficiently accurate speech recognition in the helicopter cockpit environment to permit free use of the technology in this situation. It was not intended to postulate that primary flight control should be achieved by voice

command alone. Integration of the Speech Recognizer in the cockpit proved not to be a trivial task, it was necessary to investigate and correct various technical errors in the aircraft's audio system, to modify the machine's power conversion system significantly and to deal with both inductive and audio pick-up. To enable the aircraft to be controlled adequately by the inherently low frequency voice command it was necessary to design and implement a suite of advanced control systems which could blend and switch between themselves as needed without pilot intervention and without producing aircraft behaviors which would cause the pilot concern regarding the safety of his aircraft. This paper describes the processes involved in Speech Recognizer integration and control word system development and concludes that connected speech recognition is viable as a useful and realizable adjunct to the advanced helicopter cockpit. The X-31 Program is providing new options for conducting and winning close-in air combat in the future. Through the exploitation of the key EFM technologies - high thrust-to-weight ratio, multi-axis thrust vectoring, integrated flight-propulsion controls coupled with a 'pilot friendly' vehicle interface - the X-31 is pioneering dynamic post stall flight for a variety of combat applications. The key challenge to effective control in this arena is a compatible and properly tuned pilot-vehicle combination. The program's emphasis on control, simplicity, carefree handling, and situational awareness issues should help assure that its key objectives will be met. Various aspecs of the X-31 Program are discussed.

The Flight Systems Development branch of the U.S. Army's Avionics Research and Development Activity (AVRADA) and NASA Ames Research Center have developed for flight testing a Computer Aided Low-Altitude Helicopter Flight (CALAHF) guidance system. The system includes a trajectory-generation algorithm which uses dynamic programming and a helmet-mounted display (HMD) presentation of a pathway-in-the-sky, a phantom aircraft, and flight-path vector/predictor guidance symbology. The trajectory-generation algorithm uses knowledge of the global mission requirements, a digital terrain map, aircraft performance capabilities, and precision navigation information to determine a trajectory between mission way points that seeks valleys to minimize threat exposure. This system was developed and evaluated through extensive use of piloted simulation and has demonstrated a 'pilot centered' concept of automated and integrated navigation and terrain mission planning flight guidance. This system has shown a significant improvement in pilot situational awareness, and mission effectiveness as well as a decrease in training and proficiency time required for a near terrain, nighttime, adverse weather system. AVRADA's NUH-60A STAR (Systems Testbed for Avionics Research) helicopter was specially modified, in house, for the flight evaluation of the CALAHF system. The near terrain trajectory generation algorithm runs on a multiprocessor flight computer. Global Positioning System (GPS) data are integrated with Inertial Navigation Unit (INU) data in the flight computer to provide a precise navigation solution. The near-terrain trajectory and the aircraft state information are passed to a Silicon Graphics computer to provide the graphical 'pilot centered' guidance, presented on a Honeywell Integrated Helmet And Display Sighting System (IHADSS). The system design, piloted simulation, and initial flight test results are presented. Author (revised)

EXPERIMENTAL RESULTS IN AERODYNAMIC STABILITY AND CONTROL OF A TSTO CONFIGURATION

T. GOTTMANN and G. CUCINELLI *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 14 p (SEE N94-10421 01-02) Apr. 1993

(AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

A Winged Launcher Configuration (WLC) in a Two Stage To Orbit (TSTO) version has to fly through a wide range of angles-of-attack and Mach numbers (roughly -3 deg is less than or equal to alpha is less than or equal to 20 deg and 0.2 is less than or equal to Ma is less than or equal to 7.0). This and the requirements for horizontal take-off and landing in Central Europe, and the special separation maneuver at a hypersonic Mach number, causes a wide range of new aerodynamic and aerothermodynamic problems. Especially the problem of stability and control is increased by the wide alpha-Mach range and possibly strong engine effects. The main tasks of the experimental investigations of a TSTO configuration are to establish a data base to support the whole design process of Winged Launcher Configurations, to provide a validation base for CFD codes and to understand the very complicated problems which dominate stability, control, and stage separation aerodynamics. A generic baseline configuration of a TSTO was developed at MBB (lower and upper stage), which satisfies all requirements so far. To be able to test this configuration in all occurring speed regimes, a titanium model (size 1:160) was manufactured with an acceptable size to fit into most wind tunnels for sub-, super-, and hypersonic Mach numbers, especially at DLR in Germany and FFA in Sweden. The main part of the presentation deals with trends of the TSTO configuration in aerodynamic stability and control over the entire Mach regime, showing that some aerodynamic characteristics change significantly with increasing Mach number. Because all aerodynamic forces and moments must be balanced by the engine or aerodynamic controls to obtain reasonable flight conditions, statements regarding absolute stability and control features cannot be set up within this investigation, but tendencies can be given. Major emphasis is placed on the flap efficiency at high Mach numbers which exhibits a strongly nonlinear behavior. The separation of the upper stage was investigated in a special test phase, which shows the enormous changes in longitudinal characteristics caused by interference effects in close proximities between upper and lower stage.

CONTROL EFFECTIVENESS AT HYPERSONIC SPEEDS

J. L. STOLLERY, D. KUMAR, P. A. ATCLIFFE, and H. BABINSKY *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 10 p (SEE N94-10421 01-02) Apr. 1993

(AGARD-CP-514) Copyright Avail: CASI HC A02/MF A04

Two models equipped with trailing edge flaps were tested at a Mach number of 8.2. A simple flat plate model was used to understand how control effectiveness is influenced by transition, bluntness, and incidence, while a cropped-delta-wing spaceplane configuration has emphasized the important three-dimensional effects arising from the geometry chosen. Schlieren photographs were used to visualize the flow, and pressure measurements on the windward surface of the spaceplane model showed any regions of separation. Encapsulated liquid crystals were used to obtain an overall picture of the heat transfer distribution and to highlight the three-dimensional structure of the flow. Author (revised)

This paper presents stability analysis results which can be used to analyze the behavior of aerospace vehicles. A certain number of definitions are recalled. Liapunov stability criteria are given for autonomous systems described by ordinary differential equations and discrete-time equations. Particular attention is paid to the stability of mechanical systems around equilibrium configurations.

ON NON-LINEAR LONGITUDINAL STABILITY OF AN AIRCRAFT IN A DIVE IN THE PRESENCE OF ATMOSPHERIC DISTURBANCES
L. M. B. C. CAMPOS (Instituto Superior Tecnico, Lisbon, Portugal.) and A. A. FONSECA (Instituto Superior Tecnico, Lisbon, Portugal.) *In* AGARD, Stability in Aerospace Systems 19 p (SEE N94-11489 01-08) Feb. 1993
(AGARD-R-789) Copyright Avail: CASI HC A03/MF A03

We consider the nonlinear longitudinal stability problem of aircraft starting a dive from an initial velocity far removed from the steady dive speeds: the aim is to find a pitch control law, which will keep the aircraft in a constant glide slope, compensating for the phugoid mode. The problem is extended to account for the presence of arbitrary atmospheric winds, e.g., windshears. The theoretical stability curves are compared with flight test data, obtained using the BAFR (Basic aircraft for flight research) in Portugal. The model includes a number of effects, and has also some restrictions, which do not affect its suitability for the present application: (1) it includes compensation of the phugoid, but not short-period, mode i.e., neglects rotational inertia; (2) it accounts for boundary-layer and induced drag, but not wave drag, i.e., applies at low Mach numbers, typical of approach to land; (3) it neglects lateral motion, but allows for non-linear effects on longitudinal motion; and (4) it leads to a free-flying control law, in stall free conditions, and in the absence of autopilot or active control. These additional effects would be relevant to other applications, and would require extension or modification of the present model.

DYNAMICS AND CONTROL OF COHERENT STRUCTURES IN THE TURBULENT WALL LAYER: AN OVERVIEW
GAL BERKOOZ, PHILIP HOLMES, and JOHN LUMLEY *In* AGARD, Stability in Aerospace Systems 5 p (SEE N94-11489 01-08) Feb. 1993 Sponsored by NASA. Langley Research Center; AFOSR; ONR; and NSF
(AGARD-R-789) Copyright Avail: CASI HC A01/MF A03

We expand the velocity field in the vicinity of the wall in empirical eigenfunctions obtained from experiment. Truncating our system and using Galerkin projection, we obtain a closed set of non-linear ordinary differential equations with ten degrees of freedom. We find a rich dynamical behavior, including in particular a heteroclinic attracting orbit giving rise to intermittency. The intermittent jump from one attracting point to the other resembles in many respects the bursts observed in experiments. Specifically, the time between jumps and the duration of the jumps, is approximately that observed in a burst; the jump begins with the formation of a narrowed and intensified updraft, like the ejection phase of a burst, and is followed by a gentle, diffuse downdraft like the sweep phase of a burst. The magnitude of the Reynolds stress spike produced during a burst is limited by our truncation. The behavior is quite robust, much of it being due to the symmetries present (Aubry's group has examined dimensions up to 128 with persistence of the global behavior). We have examined eigenvalues and coefficients obtained from experiment, and from exact simulation, which differ in magnitude. Similar behavior is obtained in both cases; in the latter case, the heteroclinic orbits connect limit cycles instead of fixed points, corresponding to cross-stream waving of the streamwise rolls. The bifurcation diagram remains structurally similar, but somewhat distorted. The role of the pressure term is made clear - it triggers the intermittent jumps, which otherwise would occur at longer and longer intervals, as the system trajectory is attracted closer and closer to the heteroclinic cycle. The pressure term results in the jumps occurring at essentially random times, and the magnitude of the signal determines the average timing. Stretching of the wall region shows that the model is consistent with observations of polymer drag reduction. Change of the third order coefficients, corresponding to acceleration or deceleration of the mean flow, changes the heteroclinic cycles from attracting to repelling, increasing or decreasing the stability, in agreement with observations. The existence of fixed points is an artifact introduced by the projection; however, a decoupled model still displays the rich dynamics. Numerous assumptions made in Aubry et al. (1988) can now be proved exactly. Feeding back eigenfuncitons with the proper phase can delay the bursting, (the heteroclinic jump to the other fixed point), decreasing the drag. It is also possible to speed up the bursting, increasing mixing to control separation. Our approach is optimal for short time tracking in control. Author

(AGARD-R-789) Copyright Avail: CASI HC A03/MF A03

In a rigorous manner, aircraft motion can be described by a set of nonlinear differential equations, depending of parameters, associating the state vector (angle of attack, sideslip angle, speed ...) with the control vector (motivators) through flight dynamics equations, aerodynamic aircraft model, and flight control system. The communication presents some works which aim at a better understanding and at the precise prediction of aircraft behavior in particular flight phases for which classical linearized analysis of differential equations is insufficient or not valid. The theory of aircraft stability is at least as old as powered flight. The original impetus was to design the configuration to have acceptable characteristics. Flight control technology was next applied to tailor, i.e. improve, the classical response characteristics: a yaw damper being a simple example. More recent flight control technology has provided the means to change the character of the aircraft response so that it no longer exhibits the classical behavior of a short period, a phugoid, a Dutch roll, a roll mode, and a spiral. With additional control effectors and the use of feedback there is an infinite number of ways to change the basic stability and response characteristics. Pilot preferences are also well established, however, so that care is needed in implementing any theoretical improvements. The technology exists to provide the pilot with the capability to individually control all six degrees of freedom. Obviously, a requirement for a pilot to integrate six different control effectors would be likely to increase his workload. In that sense, decoupling all six axes would be detrimental. Conversely, any unwanted coupling that can be eliminated should reduce the pilot task. The Wright Laboratory has had a series of flight demonstration programs that have evaluated new technologies in the most realistic tasks. First, an F-16 was provided

with the additional control effectors to allow independent control of all six degrees of freedom. A variety of control modes was mechanized, so that the pilot could evaluate both coupled and decoupled modes. Following a subjective in-flight assessment, a ground-based piloted simulation experiment was performed to evaluate all modes for both offensive and defensive combat use. Second, an F-15 was modified to facilitate precise landing in adverse conditions. A special short landing mode was implemented to feature decoupling of airspeed and glideslope responses plus the integrated coupling of direct lift and sideforce control. This paper presents results from both these programs to illustrate the benefits of either decoupling or new coupling of aircraft responses. Derived from text

Results from systematic wind tunnel tests of the dynamic roll behavior of a 65 degree swept delta wing at moderate (15 to 35 degree) angles of attack are reviewed. These tests, conducted in both the IAR 2 x 3 m low-speed wind tunnel and the 7 x 10 ft SARL facility at WPAFB, included static, forced oscillation and free-to-roll experiments with flow visualization. Multiple stable trim points (attractors) for body-axis rolling motions and other hard-to-explain dynamic behavior were observed. These data are examined in light of the nonlinear indicial response theory advanced by Tobak and his colleagues. The current analysis shows that force and moment, free-to-roll motion, and flow visualization data all confirm the existence of 'critical states' with respect to the static roll angle. When these singularities are encountered in a dynamic situation, large and persistent transients are induced. Conventional means of representing the nonlinear force and moments in the equations of motion are shown to be inadequate in these cases. Alternative approaches based on simplification of the nonlinear indicial model are briefly discussed.

Quantitative feedback theory (QFT) has achieved the status as a very powerful design technique for the achievement of assigned performance tolerances over specific ranges of plant uncertainties without and with control effector failures. This paper presents a brief overview of QFT and its applications to advanced multi-input multi-output (MIMO) flight control systems. Desired performance over varied flight conditions may be achieved with fixed compensators (controllers), despite failures of effectors. QFT is the only design technique that has been able to make considerable progress in improving the design of an overall flight control system taking into account the man-in-the-loop specifications. Two control technologies have been developed and integrated towards the definition of an Integrated Flight Control for the year 2000 (IFC2000) aircraft. The control technologies considered for IFC2000 are flight control reconfiguration and post stall maneuvering. The reconfiguration technique allows an aircraft to utilize the inherent redundancy among its control effectors for maintaining aircraft's controllability after loss (or degradation in effectiveness) of one or more of its control effectors. The reconfiguration technique used in this paper consisted of redistribution of control signals after identification of a control effector failure (first stage adaptation). This technique is based on utilizing a pseudo-inverse algorithm and minimizing a performance index to redistribute pilot's commands to the remaining control effectors. Two control laws were developed for controlling the aircraft in the post stall region where the aircraft is flying at high angle of attack (HAOA) while allowing reconfiguration in the event of surface damage or actuator failure. A self-tuning adaptive control law was developed for parameter estimation and control gain tuning (second stage adaptation). The control law utilizes the Bierman's algorithm for estimating aircraft parameters, and a linear quadratic regulator for tuning the gains. A neural net control law was developed to account for nonlinearity, parameter uncertainties, and disturbances in the flight control system. The reconfiguration, adaptive, and neural net control laws have been partially integrated; the results are reported in this paper. Post-stall maneuvering is configuration sensitive requiring a high performance aircraft with relaxed static stability, thrust vectoring, and/or additional surfaces (such as canard). A generic high performance aircraft model was modified to incorporate thrust vectoring for generating pitch and yaw moments. A control structure was developed to fly the aircraft with high angle of attack at low speed. The control structure can track alpha, phi, and beta commands from pilot's longitudinal and lateral sticks and rudder pedal, respectively. The control laws were designed to give steady state tracking for fuselage pointing. Thrust vectoring was used to produce pitch and yaw moments at HAOA. The control signal distribution function of the control laws was modified to facilitate aircraft transition from and to post-stall region. Author

Flight control systems can benefit by being designed to emulate functions of natural intelligence. Intelligent control functions fall in three categories: declarative, procedural, and reflexive. Declarative actions involve decision-making, providing models for system monitoring, goal planning, and system/scenario identification. Procedural actions concern skilled behavior and have parallels in guidance, navigation, and adaptation. Reflexive actions are more-or-less spontaneous and are similar to inner-loop control and estimation. Intelligent flight control systems will contain a hierarchy of expert systems, procedural algorithms, and computational neural networks, each expanding on prior functions to improve mission capability to increase the reliability and safety of flight and to ease pilot workload. Relaxed static stability (RSS) was chosen as one of the primary technologies to be flight demonstrated on the forward swept wing X-29 aircraft. Development experiences and performance benefits of this technology in the high angle-of-attack (AOA) regime of flight are described. Flight test results validate the X-29's wind tunnel database and the updated piloted simulation is used for parameter variations to thoroughly explore the potential performance of an aircraft with high levels of static instability.

PNEUMATIC MANAGEMENT OF BLUNTED-FOREBODY FLOW ASYMMETRY FOR HIGH-ANGLE-OF-ATTACK DIRECTIONAL CONTROL

FREDERICK W. ROOS, CHARLES L. MAGNESS, and DANIEL V. BROWN *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow 6 p (SEE N94-28003 07-34) Nov. 1993 (AGARD-CP-534) Copyright Avail: CASI HC A02/MF A04

Low-speed experiments have been conducted to explore the effectiveness of combining nose bluntness, which suppresses the tendency toward flowfield asymmetry, and pneumatic flow-separation control, which triggers flow asymmetry, into a system of pneumatic side-force control for a slender forebody shape at high angles of attack (alpha). The basic forebody shape studied, a 20%-blunted, 3.5-caliber tangent ogive, developed no side force over the range 0 less than or = alpha less than or = 60 degrees. Slight blowing through either or two symmetrically positioned orifices at the blunt nose of the forebody produced a degree of flow asymmetry (and a corresponding side force) that depended on jet massflow rate within limits that varied with alpha, the specific jet configuration, and laminar vs. turbulent boundary-layer separation. Forward-blowing jets were found to be generally more effective that nets normal to the forebody surface in producing pneumatic side-force control. Derived from text

PERFORMING SPECIFICATIONS FOR COMPLEX SYSTEMS' SOFTWARE [SPECIFICATIONS EXECUTABLES DES LOGICIELS DES SYSTEMES COMPLEXES]

F. DELHAYE and D. PAQUOT *In* AGARD, Aerospace Software Engineering for Advanced Systems Architectures 14 p (SEE N94-29315 08-61) Nov. 1993 In FRENCH (AGARD-CP-545) Copyright Avail: CASI HC A03/MF A03

The role played by numerical technologies has increased with each generation of flight control systems. Most of the functions of these systems are now assumed by integrated software and to industrialize the production of these software systems is rapidly becoming a necessity. The SFIM Industries have created a system which can successfully address each phase of the life cycle. Helicopter operating is intrinsically complex and any redundancy in the control systems increases this complexity. To create specifications for such systems is difficult but it is critical, as errors in specifications are often detected in the final phases of development, resulting in costly corrections. It is thus necessary to verify the precision and the justification of the specifications as early as possible. Within its Research and Development activities in avionics, SFIM evaluated the specifications' techniques in the cycle of complex systems' development. Several techniques have been studied (structural analysis, synchronized languages, expert systems) and two of them were tested in experiments. These techniques made it possible to create and validate some of the specifications, with varying degrees of success. The positive aspect of these techniques was clearly shown, they are significant elements in the cost management program of complex systems' software. Author

DYNAMIC TESTS TO DEMONSTRATE LATERAL CONTROL USING FOREBODY SUCTION ON LARGE SCALE MODELS IN THE DRA 24 FOOT WIND TUNNEL

GERALDINE F. EDWARDS, A. JEAN ROSS, EDWARD B. JEFFERIES, and CHARLES O. OLEARY *In* AGARD, Technologies for Highly Manoeuvrable Aircraft 14 p (SEE N94-34605 10-05) Mar. 1994 (AGARD-CP-548) Copyright Avail: CASI HC A03/MF A03

The concept of applying suction at the nose of forebodies at high angles of attack to control the vortex flow was tested in two dynamic wind-tunnel experiments on large scale versions of the Defence Research Agency (DRA) High Incidence Research Model (HIRM1) in the DRA 24ft wind tunnel. The first experiment with a HIRM1 wind tunnel model mounted on a free-to-yaw rig used an analog control system. The model was controlled at angles of attack of 28 degrees and 32.5 degrees by applying differential suction through small holes near the nose apex to minimize the error between demanded and measured angle of sideslip. The second experiment used a free-flight version of HIRM1 with a digital Departure Prevention System (DPS) which was flown successfully in previous experiments. A nose suction control law, designed to maintain roll about the wind axis, was added to the DPS. The model was mounted on a rig which allowed freedom in yaw, roll, and pitch, the tailplanes could move symmetrically and differentially, and the rudder was used to augment directional stability. The model could be flown at angles of attack up to about 30 degrees, with the suction control law active, but would diverge in yaw and roll if the suction was turned off. Author (revised)

YAW CONTROL BY TANGENTIAL FOREBODY BLOWING

N. J. WOOD and W. J. CROWTHER *In* AGARD, Technologies for Highly Manoeuvrable Aircraft 10 p (SEE N94-34605 10-05) Mar. 1994 (AGARD-CP-548) Copyright Avail: CASI HC A02/MF A03

Aircraft yaw control at high angles of attack by tangential forebody blowing has been investigated experimentally. Tests were performed in the University of Bath 2.1 m X 2.5 m low speed wind tunnel using an approximately 6 percent scale generic combat aircraft model fitted with blowing slots in the nose cone. Six component strain gauge balance force and moment data was measured for angles of attack up to 90 degrees for various slot geometries and locations. The effect of slot azimuthal location is demonstrated and a slot stall phenomenon described. A geometry dependent forebody/wing flow-field coupling has been identified which can lead to unexpected yawing and rolling moments. The primary source of yawing moment is shown to be the enhanced area of attached flow on the blown side of the forebody rather than direct vortex influence. The optimum slot extent and location depend on the angle of attack range over which control is required. For regions where steady vortex asymmetry is present, slots near the apex of the forebody produce severe control reversals at low blowing rates which can be minimized by placing the slots away from the apex. For control in regions where the flow is dominated by periodic vortex shedding, long slots offer efficient control to 90 degree angle of attack. The most suitable compromise for wide range control would appear to be a short slot placed away from the apex of the forebody. Author (revised)

CONTROL OF LEADING-EDGE SEPARATION ON A CAMBERED DELTA WING

P. R. ASHILL and G. L. RIDDLE *In* AGARD, Technologies for Highly Manoeuvrable Aircraft 13 p (SEE N94-34605 10-05) Mar. 1994 (AGARD-CP-548) Copyright Avail: CASI HC A03/MF A03

Wind tunnel studies of flows over a cambered delta wing of 60 degrees leading-edge sweep at low speed have shown that the flow separates on a forward part of the curved upper surface. Although not apparent in surface pressure distributions, this separation strongly influences the position of the onset of leading-edge separation. The present paper describes a wind-tunnel study into the use of sub boundary-layer vortex generators, in the form of thin wires, to control the flow along and toward the upper-surface separation line. The control is effective because it shifts the position of the onset of leading-edge separation downstream, ensuring increased leading-edge thrust, mainly through a reorganization of the separated flow further downstream. The flow mechanisms are described, as well as the effects of wire number. Multiple wires can provide a reduction of about 16% in the lift-dependent drag factor. The implications of the study for the subsonic flight characteristics of supersonic combat aircraft are described and suggest that the vortex generators offer genuine improvements in subsonic maneuver performance. X-31A CONTROL LAW DESIGN

H. BEH and G. HOFINGER *In* AGARD, Technologies for Highly Manoeuvrable Aircraft 9 p (SEE N94-34605 10-05) Mar. 1994 (AGARD-CP-548) Copyright Avail: CASI HC A02/MF A03

Tbis paper presents an overview on the X-31A flight control law design philosophy and the technical realization of the design.

After an introduction to the FCS hardware configuration, the basic control law structure and the method used for feedback gain calculation are presented. Several elements, such as the feedforward path, gravity effect compensation, inertial and gyroscopic coupling compensation, and the pilot command system, are discussed in more detail. Simplified block diagrams of the basic flight control mode in the longitudinal and lateral/directional axis follow. Finally, the implementation of the thrust vectoring system including engagement and disengagement procedure is shown. Author (revised)

X-31A SYSTEM IDENTIFICATION APPLIED TO POST-STALL FLIGHT: AERODYNAMICS AND THRUST VECTORING
D. ROHLF, E. PLASTSCHKE, and S. WEISS *In* AGARD, Technologies for Highly Manoeuvrable Aircraft 12 p (SEE N94-34605 10-05) Mar. 1994
(AGARD-CP-548) Copyright Avail: CASI HC A03/MF A03

Flight testing of the X-31A post-stall experimental aircraft started in Oct. 1990. By the end of 1992, the X-31A flight regime had been expanded to 70 deg angle of attack, and a significant number of flight tests with dynamic post-stall maneuvers had been performed. Within the international 'Combined X-31A Flight Test Team,' DLR (the German Aerospace Research Establishment) contributes its system identification experience and capabilities to the determination of aerodynamic parameters and thrust vector control effectiveness from flight test data. After a brief description of the applied hardware and software, this paper presents recent results from flight test data compatibility checking. The identification models used for the separated evaluation of longitudinal and lateral-directional motion are introduced. This emphasizes the model reductions necessary for X-31A high angle of attack applications. Identification results of selected aerodynamic parameters are shown in comparison to wind-tunnel predictions. The identification of the X-31A thrust vector control effectiveness is addressed, and preliminary results are presented as well. An overview of future identification activities with respect to nonlinear/instationary effects in the high angle of attack regime is given. Author (revised)

IMPROVEMENT OF ENDURANCE PERFORMANCE BY PERIODIC OPTIMAL CONTROL OF VARIABLE CAMBER
G. SACHS and R. MEHLHORN *In* AGARD, Recent Advances in Long Range and Long Endurance Operation of Aircraft 7 p (SEE N94-36321 11-05) Nov. 1993
(AGARD-CP-547) Copyright Avail: CASI HC A02/MF A03

Other than in classical theory, endurance cruise is considered as an optimal periodic control problem where the state and control variables change in a periodic manner. Variable camber is introduced as a further control in addition to angle of attack and thrust setting. By periodically varying camber in a coordinated process with the two other controls, it is possible to fully exploit its potential of improving the lift/drag ratio for increasing the endurance of aircraft. It is quantitatively shown which gain in endurance performance can be achieved. Results are presented for an idealized engine model showing no control rate limitations as well as for a realistic model with constraints on control rates imposed. The numerical values for the constraints are chosen such that only slow thrust changes are admitted. Author

The aim of this paper is to give a survey of lateral jets as control system of tactical missiles. The paper is divided into four parts. The first part gives a brief analysis of new control requirements pertaining to tactical missiles, presents the advantages of lateral jet control, and describes two types of applications for missiles designed and developed by Aerospatiale-Missiles. The first example relates to the ground/surface-to-air missile ASTER which has antimissile capability; the second example concerns the antitank missile ERYX. The second part presents in detail the phenomenological aspects of lateral jets and the influence of various flow parameters and missile geometry on control system performance. The third part describes some wind-tunnel testing problems. The fourth and last part is dedicated to computation for valuation and understanding of the aerodynamic interactions. Derived from text

This paper covers problems of flight in a turbulent atmosphere. A realistic simulation of aircraft behavior in turbulent air requires different engineering models. On one hand, this means a mathematical description of random turbulence or short scale gusts. For simple problems, a computation of the turbulence velocity vector only at the trajectory of the aircraft is sufficient. In cases of detailed investigations, the generation of a 3-dimensional spatial turbulence field is necessary. Additional real time requirements imply special approaches, such as the realization of a matrix wind model. On the other hand the description of the interaction between turbulence or short scale gusts and aircraft may require complex aerodynamic models especially if the gust scale and the aircraft scale are in the same order of magnitude. The presented multi point or lifting surface models consider the wind vector at several points along the wing span under real time constraints. Based on simulation results and flight test data, the dynamic aircraft response is discussed. Single gust effects are demonstrated by examples of cross flights through the updraft of a powerplant cooling tower. Author

THE IMPACT OF NON-LINEAR FLIGHT CONTROL SYSTEMS ON THE PREDICTION OF AIRCRAFT LOADS DUE TO TURBULENCE
R. M. WARMAN *In* AGARD, Aircraft Loads due to Turbulence and their Impact on Design and Certification 8 p (SEE N95-18597 05-08) Dec. 1994

During the past ten years the extensive use of electronic flight control systems has introduced a high level of non-linearity, to the behavior of civil transport aircraft, in response to both pilot inputs and external influences such as turbulence. These systems that control, protect, and, in some instances, alleviate the loads experienced by the aircraft have had a significant impact on the prediction of aircraft loads. There is an increasing need both to model control system non-linearity to avoid designing control systems that degrade structural performance, and to demonstrate the effectiveness of alleviation systems for aircraft certification. The introduction of non-linear flight control systems presents little problem when using time-based simulations to predict aircraft loads due to discrete gusts. Frequency domain, Power-Spectral Density (PSD), analysis used to predict aircraft loads due to Continuous Turbulence (CT), however, is severely restrictive, requiring a linear mathematical model of both the aircraft and control systems. Over the past ten-to-fifteen years various analysis techniques have been

developed that provide time-based interpretations of the CT atmosphere and, therefore, means by which loads due to CT can be predicted for aircraft with non-linear flight control systems. Recent involvement in the design of Airbus aircraft has led to British Aerospace Airbus Limited taking an active role in both developing and using these non-linear analysis techniques. By drawing on experience gained during the design of recent Airbus aircraft, the impact of non-inear flight control systems on the prediction of aircraft loads due to turbulence is discussed.

TREATMENT OF NON-LINEAR SYSTEMS BY TIMEPLANE-TRANSFORMED CT METHODS: THE SPECTRAL GUST METHOD
H. LUSEBRINK and J. BRINK-SPALINK *In* AGARD, Aircraft Loads due to Turbulence and their Impact on Design and Certification 8 p (SEE N95-18597 05-08) Dec. 1994
(AGARD-R-798) Copyright Avail: CASI HC A02/MF A01

The present paper discusses the problems which occur when PSD/Continuous Turbulence (C.T.) gust methods, originally developed for linear dynamic gust analysis in the frequency plane, are applied to modern transport A/C with flight control systems, containing a variety of nonlinearities for signal shaping. Power spectral density (PSD) gust velocity intensities are defined by the von Karman power spectrum in the frequency plane, scaled by the design gust intensity U(sub sigma) (RMS). This definition of gust in the frequency plane causes the basic problems for nonlinear dynamic analysis, in contrary to the timeplane defined Tuned Discrete Gusts. Discrete Gust calculations show that aircraft nonlinearities cannot be neglected. To treat nonlinearities for C.T. there are basically three approaches (apart from linearization methods): (1) (SSB) Stochastic Simulation Based Methods (timeplane stochastic simulation), usually in combination with exceedance rate based design load definition; (2) MFB) Matched Filter Based Methods ('Worst Case Gusts'): for each load station, a search within a class of shape functions of prescribed 'spectral energy' is necessary to find that shape giving the highest load; and (3) (SG) Spectral Gust Method: uses discrete gusts having exactly the von karman spectrum, and computes the energy norm of the loadtime history. A practical method for nonlinear C.T. method should have the following characteristics: give loads consistent to existing requirements (for linear aircraft); give correlated (balanced) loads; and be straight-forward and economical, when applied for a large number of design cases to be calculated. Since the SSB methods need long simulation times and give no balanced loads (together with exceedance rate counting), and the MFB methods are very expensive, the present paper proposes the SG method. It needs only one step to derive design loads, is consistent to Design Envelope Analysis and provides correlated loads.

The Air Force Flight Test Center (AFFTC) Flying Qualities Simulator is consistently used prior to and in conjunction with flight test to identify aircraft flight control problems and also to develop, test, and validate solutions to these problems. The subject of this paper is an example of how ground simulation was vital in developing an effective software modification to eliminate a potentially dangerous aircraft flight control anomaly. Through simulation, an in flight uncommanded pitch oscillation incident was investigated and the source of the problem was identified. A potential solution was tested and validated by utilizing the simulator prior to flight test. Additional benefits were gained due to simulation studies. The project pilots were able to practice test maneuvers and emergency procedures essential to the flight test program. The preliminary work accomplished by ground simulation correctly predicted the effectiveness of the software modifications and ensured the success of an efficient and valid flight test program.

The A-320 is the first civil airliner to make extensive use of digital flight controls. Despite previous experience with this technology, developing this system quickly has proven a challenge. Flight simulation with a high degree of fidelity has played a key role in flight control development. Simulation has also complemented the flight testing of the A-320-200. Digital flight control has moved the critical areas from aerodynamic model accuracy to flight control system representation exactness. Simulator acceptance procedures had also to be adapted to address the case of closed loop controlled aircraft correctly.

Based on examples from several projects this paper reflects MBB's experience with applicability, limitations, acceptance, and effectiveness of helicopter simulation. Some of the key points are the objective and subjective validation of a simulator and various factors, which influence the acceptance by pilots. In this context it is very important to make a trade-off between simulator sophistication and required results. Other aspects of simulation effectiveness include evaluation and training of critical flight conditions prior to flight tests as well as involving the customer from early concept studies up to full mission simulations, which gives him more influence on the design and leads to better identification with the product. Simulators are currently built as simple system 'look-a-likes' and a structured or experimentally validated approach to their use and implementation as part of a comprehensive training system is lacking. This is one reason why their use in training was not always as successful as expected. This paper reviews some experiences with the application of simulators in military flight training and it reports research strategies like the development of objective performance measures in support of validation trials and future simulator development. It is proposed to prototype simulator concepts before implementing them and relevant research initiatives in this area are reviewed. Author

Effectiveness of Flight Simulation with pilot-in-the-loop can be intended rather differently depending on the context in which the simulation activities are carried out, namely in the two traditional areas of Research & Development (R&D) and Training. In the latter case, effectiveness can be considered the amount of training a simulator is able to transfer per time unit, while in the case of R&D simulation its effectiveness is related to the amount of confidence engineers can gain in the prediction of an airborne system behavior before releasing it to the real flight. Pursuing the maximization of effectiveness in these two different contexts leads to different approaches in applying simulation methodologies. This paper will show to what extent a simulation facility created and continuously improved to support the development of a new attack aircraft, the AM-X, was finally capable of training operational pilots during the conversion to that aircraft. The use of engineering simulation as a design support tool is becoming more prevalent in assisting design engineers in prototyping new concepts in advanced integrated helicopters. The primary goal in using full mission simulation as a risk reduction tool is that it can provide significant insight into critical design areas. In this capacity, it allows the research engineer the means to review critical design issues and assess areas of high risk associated with air vehicle design. The use of the Engineering Development Full Mission Flight Simulator (EDFMFS) will allow the design engineers the opportunity to view the future performance of the design air vehicle. This includes areas of both aerodynamic and operational suitability. The use of representative flight simulators will allow major design issues to be resolved with a significant reduction in the cost normally associated with developmental flight testing. The performance of flight control laws and cockpit design can be evaluated in the safe and secure environment of the simulator before actual flight test. In this regard, the capabilities of EDFMFS's have shown themselves to be an outstanding tool in evaluating advanced design aircraft during the initial design phase. Today's use of statistical and multivarient analysis techniques provides the designers with a real time quantitative capability to collect and analyze data, thus, reducing the risk associated with new product development. The methodologies used that provide the designer and pilots with the unique opportunity to evaluate different aircraft configurations in the Full Mission Flight Simulator before the design is concluded are identified. A description is presented of the analysis approach for an advanced development program using a realtime, pilot-in-the-loop air combat simulation. The program is developing and demonstrating advanced onboard flight and attack management algorithms to assist the pilot when outnumbered in air-to-air combat. A highly flexible simulation architecture allows hosting the flight test computer code in general purpose simulation computers. The simulator cockpit stations are modified to emulate the advanced pilot vehicle interface. A data collection and analysis approach is

described which isolates and measures the effects of the various systems making up the advanced fighter concept. Author

The German Government has initiated a three phase program to evaluate the use of an improved simulator for the Tornado aircraft. In the first phase of this program computer aided engineering (CAE) has built a prototype simulator, referred to as the Evaluation Unit (EU). The improvements in the EU consist of visual system upgrades to provide a CAE Fiber-Optic Helmet Mounted Display (FOHMD) for the pilot and weapon system officer (WSO), with imagery from an Evans & Sutherland ESIG-1000 image generator, as well as a six-degree of freedom (DOF) motion system. The EU was installed at CAE Electronics GmbH in Stolberg, Germany. Military and industrial representatives are conducting an evaluation of the upgraded simulator to assess its capability to provide high speed, low level, tactical flight operations training capability. A factorial analysis of variance (ANOVA) design is being used to objectively assess recorded performance data and subjective impressions data collected during simulator flights by military crews from the German Air Force and Navy. IN 1985, in anticipation of the phased replacement of the Harrier GR MK 3 by the Harrier GR MK 5, the UK version of the AV8B, the UK Air Staff issued a requirement for two mission simulators capable of fulfilling a comprehensive pilot training and evaluation task. It identified the need for simulators which would provide a wide range of psycho-physical cues with accurate flight and systems simulation, integrated with a high resolution, wide field-of-view visual system compatible with the Harrier's operational roles and inherent speed and agility. It became apparent that this would require the utilization of new technology, particularly in the area of head and eye-slaved visual displays; studies within the MoD confirm this and conclude that although innovative, the application of such technology was feasible. Some of the background and selection process are reviewed, and the mission simulators selected to meet the Royal Air Force's training needs are briefly described.

As a result of conceptual design work on future fighter aircraft and of future air/air weapons it was concluded that in future air/air combat, especially in the beyond visual range (BVR) scenario, a pilot has to be supported by means of intelligent onboard processing equipment in order to fulfill his most demanding tasks by fully exploiting the weapon system capabilities. An integrated fire and tactical flight director control system was developed for the entire air combat arena by DASA MBB's Military Aircraft Division in its manned simulator facility. A description of the developed system and the used simulator facility is given. As a first step to verify this development, the Attack and Maneuvering System (AMS) for the BVR-air combat was successfully evaluated by the German Air Force in a large scale manned realtime simulation study. It was demonstrated that such a system can significantly improve the combat effectiveness of a modern fighter aircraft in the BVR-scenario by a factor of up to 6. Author

Initial shipboard compatibility tests of the V-22 Osprey VSTOL tiltrotor aircraft were conducted aboard the USS Wasp (LHD-1) on 4-8 Dec. 1990. Pilot training and engineering analysis for the first shipboard launches and recoveries of the V-22 Osprey aircraft were conducted in the V-22 simulator at the Naval Air Test Center. During these sessions, workload data was recorded and the pilots made comments regarding the quality of the training. Quantitative comparisons of time history data were made using power spectral densities, averages, and maximum attained values. Qualitative comments were compared to the remarks made after the actual at-sea tests. Conclusions are drawn concerning the effectiveness of the training, and suggestions for future improvements are made. Author

Several studies performed at ONERA have shown the usefulness of testing the behavior of the whole aircraft with the pilot in the loop by using a research flight simulator as soon as the preliminary design of new FCE for future aircraft is undertaken. The communication presents three conceptual studies related to mission oriented control systems which were performed at ONERA's research flight facility. The description of the conceptual phase of each of these studies and, for two of them, of their further validation on full flight simulators allows a conclusion about the complementary roles of research and full flight simulators.

This report presents different methods of simulation used at Dassault Aviation for the APIS (pilot support by synthetic imagery) study. The aim of this study was to define man-machine concepts for synthetic imagery derived from onboard information and updated in flight. The imagery system provides the pilot with a comprehension and decision tool that can be used for any flight conditions (low altitude, poor visibility...) and tactical conditions. This document describes: (1) the methods used to produce static images from needs analysis, enabling a preliminary selection of acceptable images; (2) the use of workstations to generate and pilot in real time the solutions retained and to improve the representations; (3) interfacing workstations with a real-time processor and a RAFALE type simulation cabin, permitting manual or automatic execution of a 3-D trajectory in a simple scenario and used after evaluation by 10 pilots; (4) scenarios retained and results obtained as a result of these evaluations; and (5) follow up future spinoffs for the engineering of Dassault fighter aircraft.

A study was conducted on the NASA Ames Research Center's Vertical Motion Simulator to determine the effects of simulator characteristics on perceived handling characteristics. Differences in pilot opinion were found as the visual and motion parameters were changed, reflecting a change in the pilots' perceptions of handling qualities, rather than changes in the aircraft model itself. The results indicate a need for tailoring the motion without dynamics to suit the task, with reduced washouts for precision maneuvering as compared to aggressive maneuvering. Visual delay data are inconclusive, but suggest that it may be better to allow some time delay in the visual path to minimize the mismatch between vision and motion, rather than eliminate the visual delay entirely through lead compensation. The simulation results are compared with ratings from a similar in-flight simulation experiment. Author

The Advanced Flight Simulator (AFS) Complex at the Defense Research Agency (DRA) at Bedford was enhanced by the addition of a large displacement motion platform and a three channel Computer Generated Image (CGI) outside world visual system. The trial described here was the first in a series of trials aimed at validating the AFS in its present configuration and in particular at demonstrating its ability to address a wide variety of vehicle handling qualities with a high degree of fidelity and user confidence. It included a direct comparison between the ground based AFS and the Calspan Learjet in-flight simulator. The comparison between the AFS and Learjet involved three pilots flying the same offset approach landing tasks using the same aircraft model in both the AFS and in flight. The lateral handling qualities were varied by adjusting the time constant of a filter in the pilot's roll control loop. Pilot comments, handling quality, and PIO ratings indicate that the AFS reproduces the lateral handling qualities and roll PIO tendencies of the Learjet in-flight simulator with high fidelity. The degradation in handling qualities and increase in PIO tendencies with increasing filter time constant were clearly revealed in both the AFS and Learjet. The importance of good platform motion cueing and task design when evaluating handling qualities was also demonstrated. Author

A development tool called the 'visual cockpit' is discussed. A comparison of civil and military transport aircraft development shows a significant technology gap on the military tactical transport side during the last 30 years. Therefore, it seems very beneficial to consider a 'dual use' of well-proven 'civil technologies' for military applications. Specific military transport missions require aircraft capabilities, some of which are quite new and therefore challenging for transport aircraft (e.g. low level flight profiles in night and poor visibility conditions). The demonstration of the feasibility and an evaluation of technical solutions imply the need for suitable development tools. The Virtual Cockpit is explained in terms of its components (hardware/software), features, and capabilities. A major field of investigation in this context is the aircraft systems' central control and monitoring. Author

(AGARD-CP-513) Copyright Avail: CASI HC A03/MF A03

The importance of the various cues provided by flight simulators is a topic for continual debate. Designers of simulators must wrestle with the issue in order to create a sufficient illusion of flight that allows the pilot to carry out his tasks. Hopefully, he becomes stimulated in a similar manner to the real world and behaves accordingly. For training purposes, we are then reinforcing behavior patterns. In research and development simulation, we become more confident that problems or deficiencies of pilot/aircraft interaction are identified early. Clearly, if the cueing is identical to the real world, we would expect identical behavior from the pilot. Simulators invariably fall short of this in many ways. What are considered to be essential cueing requirements are often intuitive, sometimes based on experience and sometimes completely open to individual opinion. A good test of cueing effectiveness is a comparison with flight. The cueing issues for landing approach and touchdown of fast jets are discussed here and simulation results are compared with flight. TECHNICAL EVALUATION REPORT ON THE FLIGHT MECHANICS PANEL SYMPOSIUM ON PILOTED SIMULATION EFFECTIVENESS [L'EFFICACITE DE LA SIMULATION PILOTEE]

A. G. BARNES (Barnes, A. G., Lytham Saint Annes, England) Apr. 1992 17 p In FRENCH Symposium held in Brussels, Belgium, 14-17 Oct. 1991

(AGARD-AR-315; ISBN-92-835-0669-3) Copyright Avail: CASI HC A03/MF A01

This report evaluates the AGARD Flight Mechanics Panel Symposium on Piloted Simulator Effectiveness, held from 14 to 17 Oct. 1991, in Brussels, Belgium. The intention of the Symposium was to assess the benefits and the future potential of flight simulation in contributing to aircraft development, skill training, and mission training, for both fixed wing and rotary wing aircraft. In particular, contributors were asked to compare the results of simulated and real tasks. The papers were wide ranging and of high quality; several new ideas emerged. The technology of flight simulation has greatly improved since the last symposium on this topic, in 1985. The emphasis of work related to fixed wing aircraft has shifted towards systems integration. A greater contribution to helicopter design and clearance is also evident. Although new visual display devices show great promise for military flight training at high speed, low level, they are not yet fully proven, and it is recommended that an early return is made to the topic of pilot training. Simulator validation and fidelity are also of growing importance. Author

POSSIBILITIES AND LIMITATIONS OF FLYING TRAINING IN THE GERMAN AIR FORCE

H. RUEGGEBERG *In* AGARD, Combat Aircraft Noise 6 p (SEE N93-10666 01-71) Apr. 1992

(AGARD-CP-512) Copyright Avail: CASI HC A02/MF A03

Training is the most important task of our Air Force in peacetime, and simulation must be seen as an integral part of it. The rapid progress made in improving and advancing simulation techniques leads to a broader use of simulation in combat aircrew training. Pilots concern about reduction in flying hours in exchange for simulation missions has changed somewhat due to the fact that the total annual flying hours were reduced anyway and low level flying was restricted to 300 meters AGL without having any adequate substitute. Simulators are therefore more and more accepted as a necessary add-on for optimum combat proficiency training in which the simulator training portion will have to grow to approximately 30 to 35 percent of the future training program. The German Air Force has used simulators for all types of aircraft for many years and managed to install one special-to-aircraft type simulator in every wing. The experience gained with those systems should be investigated thoroughly to improve our knowledge of the possible application of simulators in combat training. But before we identify the principle interrelationships and longterm perspectives in a new training and simulation concept, we should collect all available data and analyze the finding from the evaluation and flight testing of the ongoing TORNADO simulator upgrade program. We should identify the shortfalls and initiate the necessary follow-on program and improve the prototype simulator before we come to any decision for the simulators in the TORNADO wings. Author

ASTOVL MODEL ENGINE SIMULATORS FOR WIND TUNNEL RESEARCH

A. E. HARRIS, G. L. WILDE (TKD Ltd., England), V. J. SMITH (TKD Ltd., England), A. R. G. MUNDELL (Defence Research Agency, Farnborough, England), and D. P. DAVIDSON (Rotadata Ltd., Derby, England) *In* AGARD, Aerodynamic Engine/Airframe Integration for High Performance Aircraft and Missiles 10 p (SEE N93-13199 03-34) Sep. 1992

(AGARD-CP-498) Copyright Avail: CASI HC A02/MF A04

Feasibility studies have been conducted into the use of military turbine powered simulators (MTPS) for wind tunnel research on typical Harrier/AV8B and ASTOVL aircraft. The MTPS approach has shown significant promise for full simulation of inlet airflow ratio and nozzle thrust representations. The studies were made in two parts. In the first instance, simulation of the basic Pegasus of the Harrier/AV8B was examined. A simulator at 1 to 7.5 model scale using compressed air drive has been shown to be feasible. The design develops 467 SHP and is well adapted for use in available high-speed and low-speed wind tunnels. In the low-speed facility, a strut mounted arrangement coupled to the existing external force balance presents only minor difficulties; for the high-speed tunnel further work is required to develop/refine an internal balance/sting arrangement. Overboard bleed is used in an optimized manner to match cycle requirements to the need for minimum compressed air feed and bleed cross sectional area. In subsequent studies, cycles and layouts appropriate to the evolving ASTOVL powerplants have been examined. It is shown that MTPS designs can be developed to match a representative ASTOVL layout although compromises may be required to the support strut design to suit airfeed and bleed requirements. This paper concludes with a recommendation for a staged evolution of ASTOVL model simulations which is geared to a realistic ASTOVL project timescale in a cost effective manner. Author

USE OF MICROPROCESSOR-BASED SIMULATOR TECHNOLOGY AND MEG/EEG MEASUREMENT TECHNIQUES IN PILOT EMERGENCY-MANOEUVER TRAINING

J. V. SVOBODA, RUTH M. HERON (Transportation Development Centre, Montreal, Quebec), and H. WEINBERG (Simon Fraser Univ., Burnaby, British Columbia) *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 7 p (SEE N93-19653 06-03) Sep. 1992

(AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

This paper shows how a combination of microprocessor-based simulator technology and magnetoencephalographic/electroencephalographic (MEG/EEG) techniques is being used in a program of research focusing on the effectiveness of training in precision flying in order to prepare general aviation pilots for emergency situations during take-off and landing. The simulator, representative of a light twin-engine aircraft, affords safe low-cost experimentation. Evoked potentials, obtained with application of MEG/EEG techniques and interpreted within the context of an information-processing model, are expected to add significantly to information obtained from conventional measures of performance and workload. The basic procedure in the series of studies in question involves exposure of experimental groups to simulator-generated formation flying scenarios, with instructions to follow the 'lead' pilot: in subsequent test scenarios requiring take-off and landing under engine failure and turbulent conditions, the performance of experimentals will be compared with that of controls. The paper concludes with a discussion of the safety implications of outcomes for general, military, and commercial aviation. Author

(AGARD-CP-527) Copyright Avail: CASI HC A03/MF A04

The Advanced Turbine Aerothermal Research Rig (ATARR) has been under development and construction at Wright-Patterson Air Force Base for the past three years. Construction of the facility is now complete and demonstration experiments are underway. These demonstration experiments involve use of an instrumented turbine stage (both surface pressure and surface heat flux instrumentation) to obtain measurements for comparison with predictions, flow path measurement of total pressure, total temperature, and static pressure to determine flow path uniformity, as well as instrumentation to ascertain proper operation of all facility components. At the time of this writing, the experiments designed to obtain the data just mentioned are underway but results are not available. Therefore, the written paper will be confined to a description of: (1) the facility and its design capabilities, (2) a description of the operation of the major components with limited supporting data, e.g., main valve opening and closing times, and (3) a brief description of an uncertainty analysis that has been completed for the instrumentation and aero-performance measurements. The two high enthalpy shock tunnels in Aachen and Gottingen, Germany are described. Both of these are shock tunnels operating in the reflected mode. The Aachen tunnel has a heated driver and the Gottingen tunnel has a free piston driver. The Aachen tunnel has been in operation for a number of years already and the characteristic operating conditions of this tunnel are described. The tunnel in Gottingen (HEG) is currently being established. The first commissioning results of this tunnel are being described. The Aachen tunnel TH2 covers a testing range in air from perfect gas behavior to real gas behavior with significant oxygen dissociation effects. The HEG was designed to operate in the flow regimes where also significant nitrogen dissociation dominates. Author (revised)

DESIGN AND PRODUCTION OF INSULATED WIND TUNNEL MODELS OF THE HERMES SHUTTLE FOR HEAT TRANSFER MEASUREMENTS AT HYPERSONIC SPEEDS

L. VISINTINI and C. COUEDOR (Dassault Aviation, Istres, France.) *In* AGARD, Theoretical and Experimental Methods in Hypersonic Flows 9 p (SEE N94-10421 01-02) Apr. 1993

(AGARD-CP-514) Copyright Avail: CASI HC A02/MF A04

Among all kinds of wind tunnel experiments undertaken up to now by Dassault Aviation to develop the European HERMES shuttle, those relative to heat transfer measurements could be the last to be fully accomplished. To some extent, one could say that difficulties came from sensors themselves, from their integration conditions, and finally from additional similitude parameters not considered before. The paper introduces to Dassault Aviation so-called 'insulated models' and describes the ongoing activity developed with the collaboration of AerMacchi. The models have the purpose of making heat transfer measurements with correct simulation of surface temperatures due to its demonstrated effect on boundary layer transition. A number of pathfinder models were developed for this purpose: after a first attempt made by using a machinable ceramic, the second one was intended for surface temperatures up to 400 C and was made in a temperature resistant composite material, and the third one, able to sustain skin temperatures above 1000 C, is made by an insulating ceramic coating on a steel core. The fluid-dynamic and technological aspects related with the design and manufacture of these models are described. Author (revised)

The arc heated wind tunnel (LBK) of the DLR is a useful device for high enthalpy tests of thermal protection systems of spacecrafts. The facility is described concerning its capability in simulation of the gas-surface interaction phenomena at the stagnation point of space vehicles. The working area of the tunnel resulting from tests on SiC-samples is discussed and compared with other arc heated wind tunnels. To support experimental works on the LBK numerical computations including flow solutions based on chemical equilibrium, frozen chemistry, and chemical nonequilibrium were performed. It is shown that the flow field downstream the nozzle throat is nearly frozen. Finally, the upgrading concept and the proposed performance of the facility are discussed. Author

A new procedure which unifies the best of current classical design practices, computational fluid dynamics (CFD), and optimization procedures is demonstrated for designing the aerodynamic lines of hypersonic wind-tunnel nozzles. The new procedure can be used to design hypersonic wind tunnel nozzles with thick boundary layers where the classical design procedure has been shown to break down. An efficient CFD code, which solves the parabolized Navier-Stokes (PNS) equations using an explicit upwind algorithm, is coupled to a least-squares (LS) optimization procedure. A LS problem is formulated to minimize the difference between the computed flow field and the objective function, consisting of the centerline Mach number distribution and the exit Mach number and flow angle profiles. The aerodynamic lines of the nozzle are defined using a cubic spline, the slopes of which are optimized with the design procedure. The advantages of the new procedure are that it allows full use of powerful CFD codes in the design process, solves an optimization problem to determine the new contour, can be used to design new nozzles or improve sections of existing nozzles, and automatically compensates the nozzle contour for viscous effects as part of the unified design procedure. The new procedure is demonstrated by designing two Mach 15, a Mach 12, and a Mach 18 helium nozzles. The flexibility of the procedure is demonstrated by designing the two Mach 15 nozzles using different constraints, the first nozzle for a fixed length and exit diameter and the second nozzle for a fixed length and throat diameter. The computed flow field for the Mach 15 least squares parabolized Navier-Stokes (LS/PNS) designed nozzle is compared with the classically designed nozzle and demonstrates a significant improvement in the flow expansion process and uniform core region. This paper addresses the strengths of centrifuge simulation to provide the unfamiliar and severe motion environment associated with high angle of attack and post-stall maneuvering. The approach to development and testing of centrifuge motion control algorithms

is outlined, including inherent modeling constraints such as three degrees of freedom, estimated human perceptual models, and the machine-associated mechanical/structural considerations. Difficulties of algorithm development are illustrated using the results of a recent flying qualities experiment initiated to study the effects of motion on pilot ratings for proposed nose-down control power guideline criteria. Use of off-line computer models to tune algorithm performance is also presented. Finally, current capabilities of centrifuge simulation and a discussion of future applications is outlined. There is a steadily increasing tendency to use piloted flight simulators for official clearance of selected areas of flight envelopes and of system behavior or malfunctions. This is a natural and desirable evolution from the wide use of simulation during the development of new aircraft. However, there is a lack of guidance for certification authorities and aircraft manufacturers on simulation standards, validation procedures and general information on the advantages and disadvantages of using simulation as part of a clearance program. This could lead to either inappropriate use of simulators, or unnecessary (and costly) reluctance to use simulation when it is appropriate. In particular, there is concern by many involved with research and engineering development simulators that subjective pilot opinion is often the primary criterion for acceptance of simulators for certification activities. However, clearance demonstrations on a simulator will not usually be experienced in flight until an operational pilot encounters the conditions or configurations of the clearance. Thus validation of the simulator for clearance tasks must involve rigorous model and simulation system validation as well as pilot subjective tests. Subjective adjustments are unacceptable. Working Group 16 was formed by the Flight Mechanics Panel of AGARD to produce an Advisory Report on this subject. The aim was to provide advice and guidance to Certification and Acceptance Authorities, and Aircraft Manufacturers on the appropriate use of piloted simulation as the sole demonstration for aircraft and system flight clearances. The Group included members from Canada, Germany, Italy, Netherlands, United Kingdom and the United States. Government R&D Establishments, Armed Service R&D Establishments, and aircraft and simulator manufacturers were all represented. Author

Aerothermal environments as encountered during the missions of reusable spacecraft, hypersonic vehicles, advanced launchers, etc. are the major design driver for an advanced Thermal Protection System (TPS) technology. In developing such materials and structures ground testing under simulated operational conditions is of eminent importance. In order to meet these requirements IABG has designed a thermoacoustic facility which was recently put into operation. The facility is able to produce surface temperatures up to 1300 C and sound pressure levels up to 160 dB. The design approach and operational aspects from test work performed so far are described. ADAPTIVE WIND TUNNEL WALLS VERSUS WALL INTERFERENCE CORRECTION METHODS IN 2D FLOWS AT HIGH BLOCKAGE RATIOS

G. P. RUSSO, G. ZUPPARDI, and M. BASCIANI *In* AGARD, Wall Interference, Support Interference and Flow Field Measurements 12 p (SEE N95-19251 05-34) Jul. 1994 Sponsored by Ministry of University and Scientific and Technological Research

(AGARD-CP-535) Copyright Avail: CASI HC A03/MF A04

The aim of the present work is to compare the effectiveness of adaptive-wall approach with the capabilities of WIAC (wall interference assessment and correction) methods in reducing wall interference effects in wind tunnel testing. Tests have been made in the 20 cm x 20 cm subsonic Adaptive Walls Wind Tunnel in Naples. Three different models having a chord of 100 mm, 150 mm and 200 mm have been used. The corresponding blockage ratios at alpha = 0 degrees are 6 percent, 9 percent and 12 percent, respectively. Results of the tests show that wall adaptation and measured boundary condition WIAC methods are equivalent in correcting wall interference at moderate angles of incidence and/or with medium size models (i.e. at moderate blockage ratios). Furthermore adaptive walls wind tunnels can give data correctable with a WIAC method also at very large blockage ratios as high as 4 times the blockage ratio used in conventional wind tunnels. The effectiveness of a 'two-variable' scheme, for evaluating wall interference with slotted liners installed, is assessed. Test data from transonic wind tunnel tests with a two-dimensional model geometry are utilized. In these tests untypically high levels of wall interference are produced. In the first tests, solid wall liners were used, in order to establish a standard. Selected results from two further series of tests, in which slotted roof and floor liners were fitted, are then presented and analyzed. In the first of these, divergent liners were used, and it was found that the slot flows generated large disturbances in the wall shear region, causing the normal velocity of the equivalent inviscid flow to be amplified in relation to the normal velocity in the slot. An allowance therefore had to made in the proposed interference scheme to account for this amplification. With convergent wall liners, large disturbances were avoided, and no such allowance was needed. Implications of the investigation for tests in large slotted liner wind tunnels are discussed. Author

A continuous effort in the area of transonic boundary interference correction has been underway at McDonnell Douglas Aerospace for over 6 years. A method of interference correction based on force and moment increments computed from CFD solutions was proposed in 1986. An extensive validation database has been acquired of transonic wind tunnel data for a set of geometrically similar models of different sizes. An empirical model of the flow at a porous transonic wind tunnel wall has been used in conjunction with panel codes and Euler solvers to yield corrections at a variety of conditions in both the MDA Polysonic Wind Tunnel (PSWT) and the MDA Trisonic Wind Tunnel (TWT). UNSTEADY FLOW TESTING IN A PASSIVE LOW-CORRECTION WIND TUNNEL
L. KONG and G. V. PARKINSON *In* AGARD, Wall Interference, Support Interference and Flow Field Measurements 7 p (SEE N95-19251 05-34) Jul. 1994 Sponsored by Natural Sciences and Engineering Research Council
(AGARD-CP-535) Copyright Avail: CASI HC A02/MF A04

A passive low-correction wind tunnel designed for two-dimensional testing has a test section consisting of transverse airfoil-slatted side walls separating it from outer plenum chambers. The uniform spacing of the airfoil slats determines the open-area ratio (OAR). The tests described were on two sizes of NACA 0015 airfoil in plunging oscillation, and instantaneous pressure distributions were measured for different values of airfoil reduced amplitude and frequency, and over a full range of tunnel OAR. It was found that, despite the relatively large sizes of test airfoil, values of pressure, lift, and moment coefficient close to theoretical free-air values were obtained for 0.6 less than OAR less than 0.8, whereas values were much too high in the presence of solid walls and much too low in open-jet testing. Test Reynolds numbers were in the range (2.5-8.0) x 10(exp 5). Author

EVOLUTION OR REVOLUTION: THE CATCH 22 OF TACSATS
C. J. ELLIOTT *In* AGARD, TacSats for Surveillance Verification and C3I 7 p (SEE N93-29892 11-32) Feb. 1993 Prepared in cooperation with Smith Associates Ltd., Guildford, England
(AGARD-CP-522) Copyright Avail: CASI HC A02/MF A03

The potential exploitation of TACSATs is limited by a vicious circle in which users do not specify requirements which they believe to be infeasible and the space industry does not offer radically new solutions because it perceives no demand. This is the Catch 22 of the title. This paper aims to show some of the possibilities if we break out of that vicious circle. A private civilian Earth observation mission (SeaStar) is adopted as a baseline. In order to illustrate what might be possible, military payloads for surveillance, verification, and C3I are suggested, derived from land or air bases systems that either already exist or are known to be under development. It must be appreciated that these are not presented as proposed designs, merely as a kind of 'existence proof' for high performance and low cost satellites. It is possible, on the basis of this 'existence proof', to explore some of the operational consequences of the more general use of TACSATs. Author (revised)

The Defense Advanced Research Projects Agency (DARPA) is the central research and development organization of the DoD and, as such, has the primary responsibility for the maintenance of U.S. technological superiority over potential adversaries. DARPA's programs focus on technology development and proof-of-concept demonstrations of both evolutionary and revolutionary approaches for improved strategic, conventional, rapid deployment and sea power forces, and on the scientific investigation into advanced basic technologies of the future. DARPA can move quickly to exploit new ideas and concepts by working directly with industry and universities. For four years, DARPA's Advanced Space Technology Program (ASTP) has addressed various ways to improve the performance of small satellites and launch vehicles. The advanced technologies that are being and will be developed by DARPA for small satellites can be used just as easily on large satellites. The primary objective of the ASTP is to enhance support to operational commanders by developing and applying advanced technologies that will provide cost-effective, timely, flexible, and responsive space systems. Fundamental to the ASTP effort is finding new ways to do business with the goal of quickly inserting new technologies into DoD space systems while reducing cost. In our view, these methods are prime examples of what may be termed 'technology leveraging.' The ASTP has initiated over 50 technology projects, many of which were completed and transitioned to users. The objectives are to quickly qualify these higher risk technologies for use on future programs and reduce the risk of inserting these technologies into major systems, and to provide the miniaturized systems that would enable smaller satellites to have significant - rather than limited - capability. Only a few of the advanced technologies are described, the majority of which are applicable to both large and small satellites. Derived from text

Two different guidance methods are designed for the pre-launch phase in a one-versus-one air combat situation with missiles. In both guidance schemes a missile/target simulation is performed to estimate the miss distance at the end of a fictitious missile launch. A way to do this in real time is described. The first guidance method continuously evaluates the miss distance for each aircraft against the respective opponent. The guidance is such that the ratio of the rates of the miss distances takes an optimal value from the view of the guided aircraft. Thus, it reaches a firing opportunity first. The purpose of the second guidance method is to reach a firing position against a nonmaneuvering target in minimum time. Inside the guidance algorithm, the optimal pre-launch trajectory is approximated by nonlinear programming. It serves as a reference trajectory for the guidance. In simulations the influence of different missile and target strategies in the post-launch phase is examined. The comparison with an optimal trajectory shows the near-optimal character of the guidance method. Author

The need for tacsats is discussed, and typical tacsat mission requirements are identified. A spectrum of potential tacsat launch systems is identified and characterized, including both U.S. and non-U.S. systems, and ranging from existing operational vehicles to very advanced vehicles that will not become available until well into the next century. The six basic launch system design drivers are presented: performance, cost, operability, launch responsiveness, launch flexibility, and survivability. These design drivers are discussed as they relate to tacsat launch requirements. The launch systems that are described are placed in the following categories: (1) mainline launch systems; (2) small fixed/relocatable/mobile launch systems; (3) ballistic missile-derived launch systems; and (4) far-term launch systems. The impact of the U.S./CIS Strategic Arms Reduction Talks

(START) agreements on the availability of surplus ballistic missiles is discussed. The availability and utility of a wide selection of global launch sites are also examined. It is concluded that the general tacsat mission is a viable concept, and possibly satisfies a very critical future need. It is demonstrated that the tacsat launch services needs into the foreseeable future can be supported by current and planned launch systems launched from existing launch sites. However, numerous other options are available and should be investigated by the tacsat system designer/planner for viability and cost effectiveness. Author (revised)

There has been a need for generic technologies and common approaches in design, development, and manufacturing of military and commercial products. This need is more pronounced and pressing today than ever before. With the objective to dramatically enhance avionics reliability, maintainability and availability (RM&A), an integrated, generic technology for packaging, cooling, and interconnection of high density and high performance circuits was developed. It is named High Density Monolithic Packaging (HDMP). Under the sponsorship of Wright Laboratory, a two-part complementary program (1990-1994), named Advanced Radio-Frequency Packaging/ARFP was contracted to Westinghouse. Under the ARFP program, the HDMP technology is being applied and its promising capability is being assessed for its ability to reduce the low power RF avionics life-cycle cost. Being better than half way through the program, the results and projections have been extremely promising. The technology assessment is approximately 50 percent complete and initial results have been extremely successful. Although the focus of the development effort has been on RF subsystems, the basic elements of HDMP technology have applications beyond RF/microwave subsystems. As digital processing speeds increase, RF/microwave design techniques must be applied to maintain high speed digital signal integrity. The basic elements of the HDMP technology are: low temperature co-fired ceramic (LTCC), solderless interconnects, multichip modules (MCM's), and composite heatsink materials. The key technology element, in this avionics availability enabling technology, is LTCC. LTCC material technology is a monolithic multilayered ceramic and conductor/metallization structure used as a substrate to support dense co-habitation of high density electronic circuits, their interconnections, and the electromechanical integrity of the integrated constituents. The Hermes spaceplane will represent a major step in the European space activities. It will be placed into orbit by the heavy-lift launcher Ariane 5. After completion of the mission, it will glide back from low earth orbit to its landing site. In order to take the different problems linked to the ascent and the reentry phases, an aerodynamic strategy was set up. A global review of this strategy will be made. It will contain elements on the available and necessary tools (experimental and theoretical) for the Hermes definition and qualification phases. Some aspects such as the design of the Hermes spaceplane will also be highlighted. It will review the different constraints that will be faced during the ascent and reentry phases. Constraints may come from mission requirements such as crossrange capability or from technology limits such as thermal limits on the thermal protection system or from guidance and control requirements. A new methodology was selected in order to take constraints and uncertainties into account in the design oriented towards qualification of the Hermes spaceplane. The main line of this methodology is the projection on a typical reentry trajectory of the uncertainties in the aerodynamic characteristics checked on control points. Author

The requirement of the design process of hypersonic vehicles to predict flow past entire configurations with wings, fins, flaps, and propulsion system represents one of the major challenges for aerothermodynamics. In this context computational fluid dynamics has come up as a powerful tool to support the experimental work. A couple of numerical methods developed at MBB designed to fulfill the needs of the design process are described. The governing equations and fundamental details of the solution methods are shortly reviewed. Results are given for both geometrically simple test cases and realistic hypersonic configurations. Since there is still a considerable lack of experience for hypersonic flow calculations an extensive testing and verification is essential. This verification is done by comparison of results with experimental data and other numerical methods. The results presented prove that the methods used are robust, flexible, and accurate enough to fulfill the strong needs of the design process. Author (revised)

The concept of a Tactical Space System (TACSAT) is a means to provide a rapid, on demand, augmentation of the backbone U.S. military space systems. Such augmentation would be valuable to temporarily replace lost capability or in times of crisis, to accommodate surge demands. Because augmentation needs are not always known a-priori, it would be desirable to be able to rapidly constitute the appropriate payload-satellite bus combination to accommodate the need for a specific space capability. To do this, one can envision a standard bus capable of accepting a variety of payloads, or better yet, a single spacecraft designed to perform several different missions. Both options are considered. A number of potential missions exist in the areas of surveillance, navigation, environmental sensing, and communications. Of these, two are presented as strawman concepts: surveillance and communication. For surveillance, an electro-optical payload is described that could be used for missile surveillance, theater targeting, or weather data using the same optics, focal plane, and processor. The satellite orbit selected dictates which mission is performed. For communication, both SHF and EHF payloads are defined to provide theater coverage for the tactical user. The advantages and penalties that accrue to the use of a common bus are also explored. In addition, launch options are identified and a comparison made between 'launch-on-demand' and 'launch-on-schedule' strategies. Potential timelines for rapid launch are shown based on parallel processing and checkout of spacecraft

and launcher. This technique is compared with launching satellites on a routine basis and storing them in orbit. Energy requirements for repositioning these stored satellites after they are activated in time of need are defined. Author (revised)

The object of this presentation is to propose a navigation system functioning according to the same principle as the GPS system but which would offer a permanent service in Europe using a limited number of satellites. The constellation presented here requires only 4 satellites including one geostationary and three satellites on geosynchronous orbits of weak inclination and eccentricity. This constellation makes it possible to completely cover Europe, the Middle-East and Africa. Moreover, the use of relatively simple satellites is possible. Indeed, all the satellites being permanently visible from the same point of the globe, it is possible to leave on the ground the ultrastable clock which provides the time reference for measurements of user-satellite distance. This constellation appears promising and a more thorough analysis is in hand in order to judge the feasibility of such a system. In particular, the problems arising from the setting and the maintenance in position of such a constellation are being analyzed right now. Several possible solutions for the installation, with single or multiple launches, from standard transfer orbits or not, are presented here. In order to provide a first evaluation of the cost of maintaining it in position, the influence of the main disturbances of orbit on the service provided was analyzed. Some examples of the maintenance in position are also provided. Transl. by FLS

The ability of a tactical communication satellite (TACSAT) space system to fulfill its mission application with the desired capability, responsiveness, reliability, and survivability, while at the same time achieving low cost objectives, is a tremendous challenge that can only be met if all of the system segments - launch, space, and ground - contribute to meeting mission unique requirements. The emerging concepts for the development, deployment, and operation of cost-effective TACSAT space systems are especially dependent on the flexibility and operability of their launch vehicle and spacecraft bus systems. Orbital Sciences Corporation (OSC) has privately developed two flexible yet cost-effective space launch vehicles--Pegasus (TM) and Taurus (TM)--with significant and unique operational capabilities that enable TACSAT space systems to meet these challenges. The Defense Advanced Research Projects Agency (DARPA) has sponsored the first launch of both systems, with follow-on launches scheduled in support of U.S. Air Force, NASA, SDIO, and commercial programs. In addition, OSC has developed a flexible, cost-effective, spacecraft bus--PegaStar (TM)--that makes common use of the Pegasus or Taurus final stage avionics and structure in an integrated systems approach, thereby optimizing the mass and volume available for payload sensors. PegaStar spacecraft for the Air Force and NASA are now in engineering and production. Author (revised)

The QuickStar System is not a concept--it is a flight-proven design. QuickStar is a small, highly capable, low-cost, lightweight spacecraft using modern design techniques that can carry tactical assets into space at a tenth of the cost of current systems. System design, relevant technologies, payload capabilities (mass, power, data rate, pointing, volume), and tactical mission applications of this lightweight satellite are described. As part of the overall small satellite system architecture, a portable, low-cost multipurpose ground station to support production, test, launch, and orbit operations of the space segment is also available. The versatility and transportability built into the ground station allows placement at any government installation or field site. The prototype QuickStar space segment was developed to ride as a secondary payload on a McDonnell Douglas Delta 2 series expendable launch vehicle (ELV). With the extra performance provided by the Delta 2 or other ELV of similar configuration, as many as four satellites could be orbited at one time. In addition, the paper describes a QuickStar satellite configuration, incorporating the same subsystems and capabilities as the prototype QuickStar, designed for stand-alone ELV (Scout or Pegasus) launchings. The program schedule for the design, fabrication, and test of a QuickStar satellite system reflects the fast-paced environment of a low-cost program. Minimal paper and much concurrent engineering goes into a schedule that provides a flight-ready spacecraft and supporting ground station in only 15 months. Author (revised)

An attempt has been made to identify the configuration, the equipment, and the necessary technology of an Attitude- and Orbit Control Subsystem (AOCS), which can provide the necessary flexibility for serving the large variety of TACSAT mission objectives and the associated performance requirements. This discussion is based on more than 20 years of experience in AOCS design and development for communication and application spacecraft (S/C). Author (revised)

Cost and performance technology breakthroughs in recent years have made possible the near term development and deployment of a low cost TACSAT surveillance system. The potential for both

the spacecraft and sensor to be launched on lower cost launch systems is the fundamental basis for reduced system cost. Additionally, the spacecraft and sensor must be amenable to low cost mass production. For all weather, day/night surveillance, an active synthetic aperture radar (SAR) is the ideal instrument, and the ability to mass manufacture thousands of very low cost transmit/receive (T/R) modules was developed at Hughes. Since the size of a SAR increases as the orbital altitude is increased, a final element of the economical basis for a low cost TACSAT is the definition of low earth orbit (LEO) space constellations with high mission utility. Tradeoffs are also provided to compare sparse or zero based peacetime constellations with surge launch capabilities to small peacetime early warning space constellations that can also instantly provide regional combat support on demand. The key space system features required to provide effective support to military field units are discussed and Lockheed's concept to fill critical niches in military surveillance and remote sensing is discussed. The military is aware of benefits available from more effective use of space. To provide those benefits, space systems must be dependable, easy to use, flexible, responsive, and affordable. How a programmable, multi-spectral E-O sensor combined with a new small satellite bus and supporting command and control and data processing tools can provide environmental and surveillance support to users in peacetime, crisis, and combat is discussed. Also discussed are how such a system meets essential military utility criteria and an approach for rapid TacSat system development, evaluation, and deployment. Author (revised)

Design of ballistic planetary entry probes for planned ESA/NASA Titan, Mars, and Earth-Return missions is discussed with emphasis on the common design constraints. The choice of aeroshell configuration and some of the simple design rules are outlined which are used initially at pre-feasibility stages. These include the influence of body dynamics, conventional aerodynamics, and aerothermodynamics. Prediction of the aerothermodynamic environment and influence of uncertainties in the basic physics and chemistry are seen to dominate. Analysis methodology and some of the ESA sponsored experimental program which was initiated to tackle the lack of basic chemistry data is discussed. Author (revised)

A modal analysis study, representing one of the anticipated 'Cooperative Spacecraft Structural Dynamics Experiments on the NASA Langley CSI Evolutionary Model', was carried out as a sub-task under the NASA/DLR collaboration in dynamics and control of large space systems. The CSI evolutionary testbed (CEM) is designed for the development of Controls-Structures Interaction (CSI) technology to improve space science platform pointing. For orbiting space structures like large flexible trusses, new identification challenges arise due to their specific dynamic characteristics (low frequencies and high modal density) on the one hand, and the limited possibilities of exciting such structures and measuring their responses on orbit on the other. The main objective was to investigate the modal identification potential of several different types of forcing functions that could possibly be realized with on-board excitation equipment using a minimum number of exciter locations as well as response locations. These locations were defined in an analytical test prediction process used to study the implications of measuring and analyzing the responses thus produced. It turned out that broadband excitation is needed for a general modal survey, but if only certain modes are of particular interest, combinations of exponentially decaying sine functions provide favorable excitation conditions as they allow to concentrate the available energy on the modes being of special interest. From a practical point-of-view structural nonlinearities as well as noisy measurements make the analysis more difficult, especially in the low frequency range and when the modes are closely spaced. The general equations for a multi-body space system with internal control forces are written. Single body, or 'local', equations of motion are written and then they are transformed into global equations, associated with a sufficient number of 'internal' equations describing the relative motions of the various parts of the system. In such a transformation, quantities of two orders of magnitude arise: the first group is associated with the Earth's equatorial radius, and the second group is associated with a characteristic length of the spacecraft. The two groups are separated in order to avoid round-off errors. Furthermore, a law of control associated with deformations of the connections between the elements of the system is introduced, in such a way that

efficient control of instability phenomena may be possible. Numerical examples complete the work. Author

(AGARD-CP-534) Copyright Avail: CASI HC A02/MF A04

Control jets are used on space vehicles in order to replace or complement mechanical aerodynamic controls at high altitudes. As a matter of fact, the efficiency of mechanical controls decreases drastically with higher rarefaction levels of external flow. Control jets were experimentally investigated in wind-tunnels. The jets interact with external hypersonic rarefied flows. Jet efficiency and associated interaction mechanisms were analyzed for two types of configurations. The first configuration is a delta wing with transverse control jets issuing from sonic nozzles located close to the trailing edge. Tests are performed with an external hypersonic air flow characterized by a Mach number of about 8, a Reynolds number of 11,000, and a rarefaction parameter V = 0.077. The second configuration is a corner flow interacting with a transverse jet issuing from one hypersonic nozzle. This nozzle is inserted in one of the two walls which make up the corner model. Tests are made under external hypersonic nitrogen flows characterized by a Mach number of about 20 and dynamic pressures ranging from 20 Pa to 620 Pa covering rarefaction levels associated with reentry conditions. The Italian satellite (with a large Dutch contribution) SAX is a scientific satellite which has the mission to study roentgen sources. One main requirement for the Attitude and Orbit Control Subsystem (AOCS) is to achieve and maintain a stable pointing accuracy with a limit cycle of less than 90 arcsec during pointings of maximal 28 hours. The main SAX instrument, the Narrow Field Instrument, is highly sensitive to (indirect) radiation coming from the Sun. This sensitivity leads to another main requirement that under no circumstances the safe attitude domain may be left. The paper describes the application software in relation with the overall SAX AOCS subsystem, the CASE tools that have been used during the development, some advantages and disadvantages of the use of these tools, the measures taken to meet the more or less conflicting requirements of reliability and flexibility, and the lessons learned during development. The quality of the approach to the development has proven the (separately executed) hardware/software integration tests. During these tests, a neglectible number of software errors has been detected in the application software. Derived from text

Tactical satellites (TacSats) are studied to determine their utility in meeting the needs of theater commanders. Six mission areas are studied: battlefield surveillance, communications, tactical missile warning and assessment, regional maritime surveillance, navigation, and weather. The synergistic role between strategic and tactical satellites is also considered. TacSat system concepts are provided in most mission areas as are means of implementing TacSat systems, including the launch and ground system segments. Issues raised in these areas are discussed. Finally, TacSat costs are discussed and the Working Group's conclusions and recommendations are provided. Author (revised)

The feasibility of installing SAR's on board lightsats for tactical and strategic observation missions is discussed, emphasizing high resolution and short revisit intervals as main system drivers. Lightsat constellations design criteria are presented for both global and limited latitude belt coverage. Pros and cons of sunsynchronous versus medium inclination non-sunsynchronous orbits are discussed. Gross system trade offs for the SAR sensor are then addressed, in the specific context of a resource-limited lightsat, stressing the achievement of resolutions better than 5 m, swaths greater than 20 Km, access angles of at least 30 deg, small antenna dimensions, and a reasonable power consumption. Both X and C band SAR solutions are outlined. Data transmission alternatives are also discussed, in the context of tactical and strategic scenarios, outlining their projected performance. Constellation orbits control and platform attitude are also addressed for their impact on mission, SAR image quality and satellite design requirements. Key aspects of critical platform subsystems are also identified. Author (revised)

The payload concept covered is that of a low cost, high performance radar sensor capable of detecting and recognizing static objects within an imaged scene of the Earth's surface using the Synthetic Aperture Radar (SAR) technique. The overall system is integrated with a TACSAT platform in Low Earth Orbit (LEO) and, although only passing reference is made to this feature, the radar could also have a capability for the detection of Ground Moving Targets (GMTI). A parametric review of such a sensor in the light of the target and background features to be observed is provided. A design concept is included showing the possible hardware realization of a candidate system, as well as budgets for the mass, size, power, and pointing requirements of the instrument. Additional design features considered are the influence that short duration missions may have on hardware redundancy and the effect of short, low duty-cycle observation periods on

solar array and battery sizing. The way towards a low cost R and D demonstrator system allowing a practical investigation of the key techniques and technologies is addressed. Author (revised)

Substantial progress has been made over the past four years in characterizing and understanding the response of energetic materials and rocket motors to the energetic stimuli specified in MIL-STD-2105A. Approaches to reducing the sensitivity based upon that work are reviewed. Minimum smoke propellants with an improved performance shock sensitivity balance were formulated. Partial or complete replacement of the nitramine with phase stabilized ammonium nitrate reduced the shock sensitivity significantly at a performance loss of 4 to 10 percent. A number of routes to more extinguishable composite propellants, both reduced smoke and high performance types, are discussed. Replacement of the polybutadiene with alternative polymeric backbones has yielded more extinguishable compositions. The use of metal perchlorates in place of the ammonium perchlorate greatly increases thermal stability. In the area of inert components, alternatives to monolithic metal cases, such as composite cases, substantially improve the response to fast cook-off and, for minimum smoke propellants, to bullet impact. The Conference Proceedings contains 15 papers and a Keynote Address presented at the Propulsion and Energetics Panel 79th Symposium on 'Airbreathing Propulsion for Missiles and Projectiles' which was held 11-15 May 1992 in Villepreux, France. The Symposium was arranged in the following sessions: Ramjets and Ramrockets: Survey papers; Ramjets and Ram Rockets: Propulsion Systems; Ramjets and Ram Rockets: Combustion, Fuels, Materials; Projectile Airbreathing Propulsion; Aerodynamics and Engine Integration; Turbojets and Turborockets; and Common Techniques. The Technical Evaluation Report is included at the beginning of the Proceedings. Questions and answers of the discussions follow some of the papers. Nineteen additional classified papers will be published in a classified volume. The Symposium was intended to be a forum for discussing advances made in this field since the conduct of a similar Symposium in the autumn of 1981. For individual titles, see N93-17608 through N93-17622.

RAMJET PROPULSION FOR MISSILES IN THE MACH 3 TO 4.5 RANGE [PROPULSION PAR STATOREACTEUR POUR MISSILES DANS LE DOMAINE MACH 3 A 4,5]
JEAN-MARIE LAURENT and PASCAL GARNERO *In* AGARD, Airbreathing Propulsion for Missiles and Projectiles 9 p (SEE N93-17607 05-20) Sep. 1992 In FRENCH
(AGARD-CP-526) Copyright Avail: CASI HC A02/MF A03

New requirements that call for increases in range and improved penetration ability have forced the newest generation of missiles to fly higher and faster. Ramjet propulsion lends itself well to these requirements. However, the most recent technical specifications are very demanding when compared to those that were required of the first generation of missiles. The following topics are presented: air intakes; fuels; thermal protection of the combustion chamber; and forecasting and testing facilities. The technologies necessary for the production of missiles capable of speeds in the Mach 3-4.5 range exist, but the costs of these technologies must be reduced in order to facilitate the development of such missiles. Future developments in the propulsion of ramjet powered missiles will aim to widen the launch envelope, extend the operating range, and lengthen the period of powered flight to give a more potent terminal maneuver phase. In this paper, some of the possible methods of achieving these aims were critically assessed for typical stand-off and air-to-air missiles. For both types of missile, the use of a high density fuel for the main propellant would produce quite significant performance gains. However, storage and plume visibility problems have to be overcome. Gains can also be made for both missiles by optimizing the relative amounts of boost and main propellant to match the required launch envelope. The benefits of inlet and exhaust variability were explored for the stand-off missile. The latter option is the more favorable prospect for range enhancement, but the design of a low pressure loss variable mechanism will be difficult. The range of the air-to-air missile depends primarily on its launch Mach number and the range can be further increased by using a highly lofted trajectory with an unpowered terminal phase. The maximum and minimum fuel flow rates needed for this missile are related to the altitude limits of its flight envelope. Author

DEVELOPMENT TESTING OF THROTTLEABLE DUCTED ROCKETS
HANS-LUDWIG BESSER *In* AGARD, Airbreathing Propulsion for Missiles andProjectiles 13 p (SEE N93-17607 05-20) Sep. 1992
(AGARD-CP-526) Copyright Avail: CASI HC A03/MF A03

Throttleability, being a current requirement for modern air-breathing missile propulsion systems, adds considerable complexity to the development of ducted rockets. Problems are especially inherent in the development of the following: (1) pressure sensitive propellants; (2) hot gas valves (especially for particle laden flow); and (3) ramcombustors featuring high performance over widely varying operating conditions. The use of propellant ingredients with high heating value but unfavorable combustion characteristics, like boron, is an additional challenge in the development of high energy ducted rocket systems. Extensive testing and a well conceived test philosophy are needed to achieve satisfactory development results. MBB, together with its subsidiary Bayem-Chemie, has been engaged in the field of throttleable ducted rockets for more than a decade. This paper summarizes test procedures which were established to address the strongly interrelated development problems and presents examples of test results derived from the development of a ducted rocket engine for a supersonic antiship missile. Procedures for designing and maximizing the performance of Dual Combustor Ramjet (DCR) engines and vehicles powered by this engine are presented. Comparisons of DCR powered vehicles with scramjet powered vehicles for Mach 4 to 8 flight show that the DCR provides better performance at the Mach 4 flight condition, while the scramjet is better at Mach 8. Comparisons of the DCR

with a ramjet for Mach 3 to 6 flight, with both having the same, but low, thrust level at Mach 3, show that the DCR exhibits better performance at and near the cruise condition at Mach 6 and similar performance during acceleration. Suggested additional comparisons to broaden the scope of the conclusions are also given. Author

(AGARD-AR-287; ISBN-92-835-0699-5) Copyright Avail: CASI HC A12/MF A03

The Propulsion and Energetics Panel's Specialists' Meeting in autumn 1985 on Smokeless Propellants demonstrated that no common standard was available in this field and that the lack of common understanding led to misunderstanding amongst the NATO community. After some preparatory discussion, the Panel, therefore, formed Working Group Number 21 with the objectives of defining methods for the assessment of rocket motor exhaust optical properties in the visible and in the infrared range, and of recommending a terminology based on quantitative criteria. The Working Group discussed the subject in a total of eight sessions and prepared this Advisory Report. Following an Introduction and Summary there are six chapters, commencing with an Overview and continuing with Propellant Smoke Classification, Plume Primary Smoke, Plume Secondary Smoke, Plume Radiation and Plume Microwave Properties. In most cases, the conclusions and recommendations follow the chapters and are not repeated at the end of the report. Author (revised)

The paper reviews the advantages and limitations of electric propulsion for lightsats characterized by a launch mass in the 300 to 800 kg range. The considered systems include ion propulsion, arc jets, and stationary plasma thrusters for different applications such as drag compensation, orbit raising, fine trimming of orbital parameters, and various orbit transfers. Electric propulsion provides substantial mass savings and turns out to be an enabling technology for certain lightsat missions. The constraints resulting from DC power limitations on board small satellites are discussed, along with the implications on candidate technologies and system solutions. A review of near term prospectives of low power ion thrusters, for lightsats applications, concludes the paper. Author (revised)

Requirements for missile guidance and stealth properties are changing and becoming more stringent. There is no up-to-date synthesis relating rocket motor plume properties to these new requirements. The work performed and recently finished within PEP WG 21 formed the basis for this Lecture Series. The scope of the Lecture Series will be rocket motor exhaust products and plumes in all their aspects. Plume properties are addressed and methods of numerical simulation and experimental assessment described. Specifically, plume structure, after-burning phenomena, primary and secondary smoke, plume radiation signatures, and plume microwave interactions are described in detail. Operational aspects linked to these topics discuss how rocket plumes influence missile detection, guidance, and tracking. Ways in which plumes may be modified to reduce or eliminate this influence are suggested. For individual titles, see N94-15218 through N94-15223.

(AGARD-LS-188) Copyright Avail: CASI HC A03/MF A03

The exhaust from a solid propellant rocket motor usually contains condensed species. These particles, also called 'Primary Smoke', are often prejudicial to missile detectability and to the guidance system. To avoid operational problems it is necessary to know and quantify the effects of particles on all aspects of missile deployment. A brief description of the origin of the primary smoke is given. It continues with details of the interaction between particles and light as function of both particles and light properties (nature, size, wavelength, etc). The effects of particles on plume visibility, attenuation of an optical beam propagated through the plume and the contribution of particles on optical signatures of the plume are also described. Finally, various methods used in NATO countries to quantify the primary smoke effects are discussed. Author (revised)

Current requirements for missile systems increasingly stress the need for stealth capability. For the majority of missile systems and missions, the exhaust plume is likely to be the major contributor to overall missile signature, especially considering the recent developments in low emission and low Radar Cross Section coatings for motor bodies. This implies the need for the lowest possible rocket exhaust signature over a wide range of frequencies from the UV through visible and IR to microwave and radio frequencies. The choice of propellant type, Double Base; Composite etc, plays a significant part in determining the exhaust signature of the rocket motor as does the selection of inert materials for liners, inhibitors, and nozzles. It is also possible with certain propellants to incorporate additives which reduce exhaust signature either by modifying the chemistry or the afterburning plume or more significantly by suppressing secondary combustion and hence dramatically reducing plume temperature. The feasibility of plume signature control on the various missions envisaged by the missile designer is considered. The choice of propellant type and hardware components to give low signature is discussed together with performance implications. Signature reduction results obtained over a wide range of frequencies are also presented. Author (revised)

The open literature on secondary smoke formation, prediction, and classification is briefly reviewed. This review was limited to the open literature in order to promote the widest possible discussion within the AGARD engineering community. The recently completed PEP WG 21 proposal for smoke classification is presented. Secondary smoke is defined and the physics of condensation of vapor onto droplets is reviewed. The basis for the existing droplet condensation models is discussed and the existing methodology for predicting secondary smoke light attenuation and scattering is presented. Test data taken to establish the initial conditions for heterogeneous nucleation in rocket plumes is presented. Comparisons between secondary smoke predictions and flight data are presented. The state of the art of secondary smoke modeling is discussed and suggestions are made for improvements. Author

The varied processes occurring in rocket motor exhaust plumes and methodology for simulating these processes are described. Rocket motor plumes contain shock waves due to under/overexpansion; the exhaust mixes with the external stream in a highly compressible turbulent environment; unburnt products of combustion after-burn strongly at lower altitudes; and solid propellant plumes contain particulates which are generally out of equilibrium with the gas-phase exhaust. Earlier methodology simulated the varied processes using boundary layer type coupling. Current methods implement solutions of the full or reduced (parabolized) Navier-Stokes equations where all fluid dynamic and thermochemical processes are strongly coupled. Earlier methodology are reviewed briefly while the status of current methods is addressed in greater detail. Author (revised)

Glow discharge flow visualization experiments are demonstrated which have been performed to enable a first assessment of the HERMES 1.0 leading edge thruster configuration concerning interference between the thruster plumes of the reaction control system (RCS) and the surrounding flow field. The results of the flow visualization tests are presented in exemplary selected photographs. Additional Pitot pressure measurements support assumptions concerning interference induced pressure changes that may result from the observed significant flow field disturbances. Author

The purpose of this workshop was to identify the current state of the art in key issues related to compression loading and fluid effects in composite materials. In the area of compression loading, there was considerable concern over the different results obtained from various test methods. It was agreed that failure modes produced by the various test methods along with a better fundamental understanding of compression failure were key issues in the development of compression test methods. In the area of fluid effects, a lack of a comprehensive data base hampers identification of key mechanisms leading to fluid degradation. This is further complicated by the fact that interactions depend on the fluid and composite under consideration. For individual titles, see N92-33034 through N92-33054.

Compression loading causes difficulty in development of test methods and failure criteria. Compression testing has produced considerable controversy with a number of different experimental methods being considered. Each method, however, often produces different values of apparent compression strength. The failure mode is the key issue, as each test may produce a different failure mode. In addition, the failure modes often depend on fiber and matrix properties and on laminate geometry. When data is reported, the failure mode is often ignored. In analyzing failure modes, one must consider how relevant the test geometry and load introduction is to the actual application for which the data is being generated. Development of failure criteria also creates difficulty because of the various possible failure modes. Author

The measured compression strength of advanced composites is sensitive to specimen inhomogeneities, loading geometry, and test conditions. Consequently, the reported strength is not an intrinsic material property, but simply the failure stress under compression loading, and varies widely for a given composite system. To obtain a more accurate measure of the material property, premature failure must be avoided, and a specimen was specifically designed for this purpose. The specimen is a miniature sandwich beam with identical composite skins on either side of a neat resin core, and can be tested in axial compression as well as four-point flexure. The axial compressive properties of epoxy composites reinforced with carbon, glass, and boron filaments, and composites of carbon fibers in a polyetheretherketone (PEEK) matrix has been evaluated with this specimen in an IITRI test fixture. Failure occurred predominantly in the gage section for unidirectional composites at composite stresses and strains substantially higher than those observed with all-composite test coupons and with substantially less variation in the data. Multidirectional laminates also displayed higher strengths with the sandwich specimen. Author

To keep the overall mass of combat aircraft to a minimum level, and to optimize performance, designers have exploited the benefits offered by advanced polymer composite materials. The ability to resist load in compression is, however, particularly important in some aircraft structures such as wings. Advantages in terms of reduced mass and increased performance to be gained with composite materials is highlighted in this paper. A general overview is given of the materials science aspects of compression and compression after impact. Recent developments aimed at improving the reliability of compression test data is reviewed. The analysis of failure mechanisms for laminated composite materials depends on obtaining a three dimensional analysis of the elastic stress and deformation in the material, with particular regard to interlaminar stresses. A transfer matrix method is used which determines the stress and displacement at any point in the plate in terms of the stress and displacement at a reference surface. Standard two dimensional equations governing these surfaces may be solved by numerical methods. Elastic buckling of plates subject to pre-stress is investigated in this paper. Buckling is treated as a bifurcation from the initial stress state, giving rise to an eigenvalue problem. Author

Results are reported of fatigue tests on a toughened graphite/epoxy (IM6/5245C) using a specimen and grip design that allows a relatively large volume of material to be tested. The loading was compression dominated with specimens having a layup of (0/45/90)-(44.4 percent,44.4 percent,11.1 percent). Specimen stiffness and residual strength were measured. Results indicate that fatigue in composite specimens is dominated by the edge effects. The proper selection of stacking sequence is crucial in achieving long fatigue lives. Under compression dominated loading, fatigue is a local process, with damage always initiating at the edge and could be related to interlaminar shear stresses. The fatigue process consists of a relatively long period before initiation, followed by a period of rapid growth leading to compressive failure. Author

An experimental investigation into damage progression in compressively loaded quasi-isotropic laminates with a circular hole and the prediction of damage initiation using 3-D finite element failure analysis is described. Notched laminated plates were fabricated from Narmco IM6/5245C with three different stacking sequences. The tests revealed that the notched strength decreased as the ply group thickness increased. Based on the numerical and experimental results, a mechanism for damage initiation and progression was proposed. However, considering the damage initiation occurred at 90 percent of the ultimate load, a damage progression model would not be practical for the material systems presently used in aircraft. Author

The DAM-STRAT finite element code is used to study the propagation of an artificial delamination between two layers of a laminate plate subjected to compression forces. The propagation is preceded by local buckling and a rupture of the layers along two sides of the rectangular delamination zone. The problem is analyzed in the framework of large displacements in the buckling and postbuckling regions. The results obtained demonstrate that DAM-STRAT is an effective tool for predicting various phenomena associated with the compression of composite panels with an initial delamination. Author

The susceptibility of currently used carbon fiber reinforced plastics (CFRP) to impact damage has stimulated the development of improved composites. This new generation of composites shows increased toughness and damage tolerance as well as improved tensile performance. This is generally not matched by an improvement in compressive properties which then become the limiting factor. To improve the compressive strength, a better understanding of the compressive failure modes is needed. For experimental verification of failure models, special attention must be paid to compressive test procedures in order to achieve optimal strength values with minimum scatter. Author

(AGARD-R-785) Copyright Avail: CASI HC A02/MF A03

While the recent development of intermediate modulus carbon fibers led to very high specific tensile strength over the first generation of high strength composites, the composite compressive properties did not improve at all. Because most aeronautical structures are subject to alternate tension and compression, it is not possible to take full advantage of carbon fiber composites, as the compressive loading becomes the design limitation. After a focus on the matrix dominating role in composite compression behavior, this paper will clear out which matrix characteristics, stiffness or strength, determines the unidirectional compressive failure. The behavior of an advanced toughened epoxy resin/carbon fiber composite material, Hercules AS-4/8552, in contact with fuel has been studied. Interlaminar shear strength and compression strength tests were performed on unidirectional specimens after being exposed at 70 C to several conditions, including a combined exposure of JP8 and water. A correlation between the fluid content and the drop of the mechanical properties was found. The exposure to fuel or additive mixtures of impacted samples was found not to produce any effect in the damage size or detectability. Fuel leakage tests were conducted on impacted panels subjected to pressure and results are presented. Finally, the growth of micro-organisms in fuel/water solutions seemed not to effect the material properties, as deduced from some mechanical and microscopy studies carried out on samples exposed to such mixtures. A study was performed to assess the effect of galvanic corrosion phenomena on the strength of graphite/bismaleimide (BMI) composites. The results indicate that degradation occurred in BMI composites galvanically coupled to aluminum alloys. The mechanism responsible for the degradation involves hydroxyl ion generation in the cathodic reaction. Optical and electron microscopy of the surface of coupled specimens showed a great deal of cracking and degradation of the resin. This phenomena is thought to be associated with stresses in the resin imposed by thermal or chemical processes. These cracks may be an indication that the mechanism of degradation is not simply the hydroxyl attack on the resin but a combination of chemical and mechanical attack. Composite-aluminum material couples were exposed to salt water/fuel solutions and to salt spray environments after which material properties were determined. Conventional protection schemes were evaluated. The results indicate that the performance retention was test specific and that the bearing tests were most sensitive to the galvanic reaction. In addition, a systematic study of the electrochemical conditions which were most important in control of the degradation rates was performed. Author

When the first application of composite materials with an organic base in the working structures of aircraft were envisaged, the greatest preoccupation of the designers and service officials was their behavior while aging. Some fifteen years later, the experience acquired in service associated with the numerous results obtained from the laboratory has greatly dissipated those fears, at least for structures not calling for extensive usage of composite technology. This does not mean that the aging of composites does not occur, but rather that the consequences are now considered to have limited and predictable impact. In other words, they are susceptible to being accounted for at the level of conception, certification, and thereafter in use in the structures. The principal steps leading to the current situation are retraced, and then analyzed to account

for the phenomena of aging, in particular the determination of the concentration of water absorbed by the composite during use. Transl.

Results of an investigation are presented into the effects of environmental exposure on the compressive fracture surface characteristics of carbon/epoxy composite materials such as Hercules AS-4/3501-6. The effects of temperature and absorbed moisture on laminates are explored. Specimens were preconditioned in either ambient laboratory humidity or in water at 64 C for four to seven weeks. The fractures were produced at room temperature and 93 C. The observed fracture features, by scanning electron microscope, of the specimens with different preconditioning and test environments are presented. These results illustrated differences in the amount of fiber/matrix separation, fiber fracture, and resin fracture with increasing temperature and absorbed moisture. The reduction in compressive strength of laminates due to hygrothermal effects is also discussed. Author

This paper examines the effects of certain heat treatments on the properties of PEEK and carbon fiber reinforced PEEK. Tests were performed to study the changes in the amount of crystallinity and observe the effect this crystallinity change had on the other properties. DSC thermograms showed that there is no considerable change in crystallinity melting point of the composite specimens dependent on the heat treatment applied. Higher glass transition temperatures were observed for specimens with a higher crystallinity percentage. The frequency effect on the dynamic mechanical spectrum was also determined, and showed that this quantity is decreased to lower temperatures and the loss tangent increases in value. Flexture testing showed that the flexture properties are independent of crystallinity. Author

Amorphous bonding appears to be a promising method of joining thermoplastic matrix advanced composites. The temperature to bond, lower than for fusion bonding, and the limited dimension of the melted zone, allow significant cost reduction and guarantee good mechanical characteristics. On the other hand, a potential problem exists, due to lower resistance to aeronautical solvents and service fluids, because of the amorphous nature of the bonding layers. The basic resistance to environmental degradation of the resins used for bonding, and the chemical stability of their blends with the semicrystalline matrices of the adherends, have been investigated. NASA Langley and the U.S. Army have jointly sponsored programs to assess the effects of realistic flight environments and ground-based exposure on advanced composite materials and structures. Composite secondary structural components were initially installed on commercial transport aircraft in 1973; secondary and primary structural components were installed on commercial helicopters in 1979; and primary structural components were installed on commercial aircraft in the mid-to-late 1980's. Service performance, maintenance characteristics, and residual strength of numerous components are reported. In addition to data on flight components, 10 year ground exposure test results on material coupons are reported. Comparison between ground and flight environmental effects for several composite material systems are also presented. Test results indicate excellent in-service performance with the composite components during the 15 year period. Good correlation between ground-based material performance and operational structural performance has been achieved. Author

DEBONDING/DELAMINATION OF COMPOSITES [LE DECOLLEMENT ET LE DELAMINAGE DES MATERIAUX COMPOSITES]
Dec. 1992 289 p Presented at the 74th Meeting of the AGARD Structures and Materials Panel, Patras, Greece, 24-29 May 1992 Original contains color illustrations
(AGARD-CP-530; ISBN-92-835-0696-0; AD-A263503) Copyright Avail: CASI HC A13/MF A03

Composite laminate components are prone to debonding/delamination when subjected to high interlaminar stress or when under impact. While delamination failure in itself is not usually catastrophic, its influence on a component may lead to subsequent failure modes. Hence debonding or delamination may reduce the strength of an aircraft or its fatigue life. The objective of the Specialists' Meeting, organized in the Spring of 1992, was to review the present state-of-the-art in the analysis, detection, and repair of delamination. Twenty-nine excellent papers were presented to an audience of over 100 leading specialists from NATO countries. Discussion of the papers presented and the final summary session revealed some common concerns and issues and gave rise to several recommendations. In bringing together the various experiences of air forces, governments, industries, and universities, the meeting has helped to identify the key issues. For individual titles, see N93-21508 through N93-21534.

The key to success in the prevention of free edge delamination is the understanding of stress components and contributing factors responsible for the onset of delamination. The contributing factors may be fiber/matrix properties, ply orientations, and stacking sequence. In the past two decades the authors have done extensive theoretical and experimental investigations on this topic. As a result of their continuous work in this area a unique software package, 'Automated System for Composite Analysis' was developed. The effectiveness of the Automated System for Composite Analysis (ASCA) for identifying the contributions of the influencing factors responsible for the onset of delamination and help select safer configurations. For this purpose two material systems (one polymer matrix composite AS4/3501 and one metal matrix composite SCS6/Ti) were considered. These two composites represent highly orthotropic and near quasi-isotropic material properties. Author

Research exploring the role of delamination on the durability and damage tolerance of advanced composite materials is reviewed. Recent studies on the characterization of composite delamination are summarized. Recent analytical solutions for interlaminar stresses and strain energy release rates associated with common sources of delamination are also reviewed. The role of delamination in (1) low velocity impact, (2) residual compression strength, and (3) fatigue is highlighted. Delamination is shown to be the common damage mode observed in all of these problems. A Damage Threshold/Fail-safety concept for addressing composite damage tolerance is discussed. Author

The total delamination moment (DM) is shown to be a quantitative criterion for predicting delamination initiation in composite laminates near free edges. To determine the initiation of delamination near free edges, DM of the laminate is compared to the critical delamination moment obtained experimentally. Specially designed specimens incorporating variable radius geometries are used to determine the critical DM. The analytical technique coupled with the experimental data is used to minimize the tendency of the laminates to delaminate without increasing the designed thickness of the laminates. In addition, residual curing stresses are included in the analytical technique to determine their effect on the initiation of edge delamination. Author

The thermoelastic effect first analyzed by Lord Kelvin is governed by a simple relation between amplitude of temperature and amplitude of sum of principle stress change as long as adiabatic conditions are maintained. Although valid for isotropic materials it is shown that this simple relation leads to very poor results for anisotropic materials. A non-adiabatic theory taken into account the inter-laminar heat transfer shows a better agreement between theory and experiment. Experimental data were obtained on a Fibredux 914C-TS-5-34 percent carbon epoxy laminate using single point measurements. Author

The need for predicting delamination or debonding in carbon fiber composite structures in two situations where the effect is crucial is highlighted. First, interior barely visible damage due to low velocity impact is discussed, and second, the debonded joint between panel and stiffener in a post-buckled compression panel is addressed. It is shown that for impact damage a stress-based failure criteria might work for thin plates less than 2mm thick but as the thickness increases a fracture model becomes necessary. A strategy for bridging this gap and also avoiding the need for a hypothetical flaw is advocated. An improved method for finding mode 3 fracture toughness is shown. Author (revised)

Currently used carbon fiber reinforced plastics (CFRP) - mainly with epoxy matrices - show a sensitive reaction to impact damage which stimulated the establishment of a cooperation program within GARTEUR (Group of Responsibles for Structures and Materials). Studies in this field had shown that delamination is a critical damage in this area for airframe structures with principal points of concern of tendency of buckling of delaminated areas and potential growth of delaminations. A new approach independent of stress intensity factors and fracture toughness parameters has been developed and is described for the computational simulation of progressive delamination in polymer matrix composite laminates. The damage stages are quantified based on physics via composite mechanics while the degradation of the laminate behavior is quantified via the finite element method. The approach accounts for all types of composite behavior, laminate configuration, load conditions, and delamination processes starting from damage initiation, to unstable propagation, and to laminate fracture. Results of laminate fracture in composite beams, panels, plates, and shells are presented to demonstrate the effectiveness and versatility of this new approach. Author

The task of the project engine designer is to determine what type, size and arrangement of propulsion system is best suited to any particular aircraft requirement. This task involves a compromise between many aspects, notably between engine or installation, performance and weight, and also, nowadays, cost as well. This compromise has to be achieved within the known or projected state of the art in thermodynamic and aerodynamic design, mechanical and structural design, and the way in which these design arts react upon each other. Most studies in engine design commence with a parametric study of the main thermodynamic variables, i.e., pressure ratio, turbine entry temperature (TET) and by-pass ratio, and their effect on specific fuel consumption (sfc) and specific thrust. This study will be based upon a given level of component efficiency which will reflect the aerodynamic state of knowledge which is considered appropriate to the estimated service date of the engine or propulsion system. Working with today's composite materials not predicted phenomena mainly related to the matrix chemical behavior can occur. Delaminations on solid laminate and honeycomb structure using a bismaleimide (BMI) resin have been detected. Analysis of the delaminated parts have been carried out to understand the nature of the defect. Correlation of the chemical behavior affecting the mechanical properties and the solution to overcome the delamination problems are described. Author

Composite materials are more and more widely used in aeronautical and spacial engineering and industry. Their main advantage is the gain in weight but it is not the only one: noncorrosion and their ability to assume complex functions without bearings are also very valuable in some cases. The drawback is the difficulty to predict their behavior and write valuable constitutive relations to perform structure computations. This is due to the microscopic heterogeneities and the various phases and interfaces whose behavior is not well-known. In this paper, we propose a homogenization method which allows, when the microscopic structure can be assumed periodic at some intermediate scale, to build a constitutive relation from the assumed knowledge of the behavior of the various phases and interfaces. A review of the literature and the research performed at the Institute for Aerospace Research on the subject of delamination in composite laminates are presented. Delamination is known to initiate at free edges where the influence of interlaminar stresses is significant. These interlaminar stresses are three dimensional and cannot be calculated by the laminated plate theory. State-of-the-art stress analysis methods for interlaminar stresses are reviewed with emphasis on the reliability of finite element methods. The strength of materials and fracture mechanics approaches for the prediction of delamination onset and growth are discussed. Results of edge delamination, double cantilever beam, and end notch flexure tests for toughened resin composites are presented. The effects of delamination on structural integrity are investigated by conducting cyclic tests on bread board specimens representing the bolted joint interface between the ply build-up ends of the composite arm booms and the metallic flanges of a sophisticated robotic system for space application. The onset of delamination at the curved edge of an open hole under compressive loading is detected using acoustic emission techniques and penetrant-enhanced x-radiography. The effects of impact-induced delaminations on the residual compressive strength of composite laminates are predicted using a model based on sublaminate buckling. Preliminary verification of the model shows good agreement between experimental and predicted results. Author

The synergism between successive layer cracking and delamination growth was studied for laminates fabricated out of T300/914C solely. Unidirectional (UD) and fiber dominated multidirectional (MD) laminates were tested after static or fatigue loading. Typical examples for damage mechanisms were analyzed numerically and used to develop damage conditions. An increase of the damage resistance was observed for MD-laminates stacked by quasi-unidirectional (plus or minus 2)-double layers (QD-layers). In crossply laminates of various stacking sequences, the crack distances were measured on the inner 90 degree-layers after T-fatigue loading. Expressions for the mean crack distances and the residual layer stiffness were developed in dependence of layer thicknesses, mean layer strain epsilon perpendicular to the fibers and number of load cycles. For the Characteristic Damage State (CDS) an energy condition was established to evaluate the crack distances A(sub CDS) for brittle matrices. In order to describe more properly the delamination growth interferred by layer cracking, a second order tensor was established for the released energy. The mean values of this tensor are the common energy release rates (ERR) for the different crack modes and the first invariant is the total ERR. But the ERR-tensor has three invariants, which can be used to establish more complex damage conditions. Author

MODE 2 DAMAGE DEVELOPMENT IN CARBON FIBRE REINFORCED PLASTICS

M. J. HILEY and P. T. CURTIS *In* AGARD, Debonding/Delamination of Composites 11 p (SEE N93-21507 07-24) Dec. 1992 Sponsored by Ministry of Defence (AGARD-CP-530) Copyright Avail: CASI HC A03/MF A03

A study of the mode 2 interlaminar fracture toughness of unidirectional carbon fiber reinforced plastics has been made using the End Notched Flexure (ENF) test. A range of fiber reinforced thermosetting prepreg systems including a bismaleimide and four epoxy materials have been investigated, plus the thermoplastic PEEK. A comparison between the materials showed the thermoplastic to be significantly tougher than any of the thermosetting systems. The two phase epoxy system 914 and the BMI V390 had the lowest toughness, with values of only 20 percent of those of the APC2 PEEK. The potential link between mode 2 fracture toughness and delamination growth and impact damage tolerance has been assessed. Measurements of delamination growth in mode 2 fatigue, for three of the materials, have also been made. Potential links with the materials susceptibility to the growth of delaminations and more generally impact damage during fatigue loading have also been considered. Author

BARELY VISIBLE DAMAGE THRESHOLD IN A BMI

EDVINS DEMUTS and RAGHBIR S. SANDHU *In* AGARD, Debonding/Delamination of Composites 6 p (SEE N93-21507 07-24) Dec. 1992 (AGARD-CP-530) Copyright Avail: CASI HC A02/MF A03

This paper presents the test plan, equipment and procedures employed and results obtained in an experimental investigation of IM7/5260 graphite bismaleimide's resistance to low velocity impact. The two velocities used were approximately 15 ft/sec for the four groups of thicker and approximately 10 ft/sec for the group of the thinnest specimens. The planform dimensions of the specimens were 7 in. x 10 in. The effect of two different layups 10/80/10 and 40/50/10 (percent of 0 degree/plus or minus 45 degree/90 degree plies) on impact resistance was investigated. There were five thicknesses for the 10/80/10 layup - 9, 26, 48, 74, 96 plies and four thicknesses for specimens of the 40/50/10 layup - 9, 27, 49, 73 plies. Four replicates were used for each combination of layup and thickness. Specimens were impacted by a free-falling steel impactor of 1 in. diameter and with a hemispherical end. During impact, specimens were sandwiched between a 1 in. thick steel bottom plate and a 0.25 in. thick aluminum plate, clammped by four corner bolts. Both plates had a central 5 in. x 5 in. opening whose center was aligned with those of the specimen and the impactor. The impactor, upon rebound, was caught thus avoiding subsequent impact. The resulting dent depths were measured with a dial gage and an ultrasonic through transmission method determined the damaged area extent. All testing was performed at room temperature. Specimens were not moisture preconditioned. Author

THE INFLUENCE OF PARTICLE/MATRIX DEBONDING ON THE STRESS-STRAIN BEHAVIOR OF PARTICULATE COMPOSITES

E. E. GDOUTOS *In* AGARD, Debonding/Delamination of Composites 9 p (SEE N93-21507 07-24) Dec. 1992 (AGARD-CP-530) Copyright Avail: CASI HC A02/MF A03

A mathematical model to predict the nonlinear stress-strain behavior of particulate composites is proposed. The model consists of a rigid circular or square inclusion embedded in a matrix across part of its boundary, while the remaining part forms an interfacial crack. The stress field in the composite plate is determined by using the theory of complex potentials in conjunction with the conformal mapping technique. The local stress field in the vicinity of the crack tip is of mixed-mode and it is governed by the values of the opening-mode and sliding-mode stress intensity factors. Initiation of debonding along the inclusion/matrix interface and growth of the interfacial crack is studied by using the maximum circumferential stress criterion. It is shown that the nonlinear behavior of the stress-strain diagram of particulate composites can be explained by studying the stable growth of the interfacial crack along the inclusion boundary. IDENTIFICATION OF DELAMINATION BY EIGENFREQUENCY DEGRADATION: AN INVERSE PROBLEM

B. STAMOS, V. KOSTOPOULOS, and S. A. PAIPETIS *In* AGARD, Debonding/Delamination of Composites 7 p (SEE N93-21507 07-24) Dec. 1992 (AGARD-CP-530) Copyright Avail: CASI HC A02/MF A03

The free vibrations of a delaminated composite beam is investigated. The effect of interply delaminations on the eigenfrequencies of the beam is evaluated both analytically and numerically in the general case of an asymmetric laminate with a delamination of arbitrary size and location. Coupling between longitudinal and bending motion is considered, which affects the natural frequencies of the delaminated beam significantly. In general the delamination causes the even numbered vibration modes to degrade, e.g. to decrease, faster than the odd ones. An inversion method to determine position and size of the delamination is proposed, based on the degradation of the first two natural frequencies. Author

INVESTIGATION OF THE BOND STRENGTH OF A DISCRETE SKIN-STIFFENER INTERFACE

H. G. S. J. THUIS and J. F. M. WIGGENRAAD *In* AGARD, Debonding/Delamination of Composites 9 p (SEE N93-21507 07-24) Dec. 1992 (AGARD-CP-530) Copyright Avail: CASI HC A02/MF A03

This paper presents the results of an experimental study on the effects of several design parameters on the strength of a skin-stiffener interface. Design parameters which are considered are skin and stiffener laminate properties and the width of the bond layer. Test specimens consisting of a blade type stiffener secondarily bonded to skin laminate were fabricated. The specimens were tested by lateral tension tests, four-point bending tests and pull off tests. Calculations were made with the numerical program BONDST. The test results are compared with each other and with the calculated results. Conclusions are drawn and design guidelines are provided. Author

PREDICTION OF DELAMINATION IN TAPERED UNIDIRECTIONAL GLASS FIBRE EPOXY WITH DROPPED PLIES UNDER STATIC TENSION AND COMPRESSION

MICHAEL R. WISNOM *In* AGARD, Debonding/Delamination of Composites 7 p (SEE N93-21507 07-24) Dec. 1992 Sponsored in part by Westland Helicopters Ltd. (Contract(s)/Grant(s): SRC-GR/G19572) (AGARD-CP-530) Copyright Avail: CASI HC A02/MF A03

The mechanism of delamination in tapered unidirectional specimens with dropped plies is discussed. Results from six sets of static tests with different numbers of dropped and continuous

plies are presented. Specimens with 2 dropped/4 continuous, 2 dropped/8 continuous, and 6 dropped/4 continuous plies were tested in tension, and specimens with 2 dropped/16 continuous, 2 dropped/32 continuous, and 4 dropped/32 continuous plies were tested in compression. In all cases failure occurred by delamination into the thick section both above and below the dropped plies. Results are compared with predictions from a simple formula based on the strain energy release rate associated with the terminating plies, with the fracture energy determined from tension tests on a unidirectional specimen with cut central plies. Good correlation was found, and this approach is recommended as a design method for predicting delamination in tapered sections. Author (revised)

Although resin injection is the procedure most often specified for repairing delaminations, field experience as well as numerous experimental investigations have shown it to be unreliable and in many cases ineffective. This paper identifies some of the reasons for this and then goes on to describe the successful development of an epoxy resin specially formulated for delamination repair. The ability of this resin to fully restore the out-of-plane properties of delaminated carbon/epoxy laminates is demonstrated, and some of the more practical aspects of repairing delaminations both on and off aircraft are discussed. High energy impact damage by projectiles is a permanent threat to all aircraft or helicopters in combat situations. Besides the actual damage extent, caused by the incident, and its effect on airworthiness, the question of the residual strength of the damaged structure arises. Based on the experimental findings on the damage extent in shot-affected APC2/AS4 composite plates, a theoretical prediction of the residual compressive strength is given in terms of strength, stability, and fracture mechanics principles. These predictions are compared with test results from four specimens, which were cut out from the original plates. It will be shown, that the delaminations, caused by the high energy impact, triggered the final compressive failure of the specimens with the start of an unstable delamination growth and that this event can be correctly predicted by a numerical analysis, if local out-of-plane deformations are taken into account. An experimental investigation was performed to establish the influence of impacts on the medium-tough CFRP material Ciba 6376/HTA. The results of this program enable a designer to dimension CFRP components. The compressive strain during impact was determined as a function of impact and impact energy. Slight increases of this compressive strain above a certain threshold resulted in catastrophic failure. Furthermore the influence of the thickness on residual strength and visible damage threshold is given. It was found, that the allowable strain limit not only depends on the impact energy but also on the laminate lay-up, especially the proportion of 0 degree-plies. Drop weight impacts show lower C-Scan damage areas compared with air gun impacts. However, the residual strain is the same in both cases. As opposed to coupons, stringer stiffened panels result in a scale-up effect of 15 percent concerning the allowable strain limit. However, this effect might change for different geometries. There have been a large number of technologies described whose purpose is to aid in the control of composite manufacture. The aim of this paper is to readdress the requirements of composite manufacture to assess which features of the various techniques are best suited to providing improved processing. To start with, the requirements of quality in manufacture and the hidden costs associated with incorrect processing are considered. This will allow us to rank the aspects of processing which it would be attractive to improve. Following this, a range of monitoring processes and their ability to deliver on these improvements and at what cost in terms of expense and complexity are considered. Monitoring processes considered include fiber-optic (optical) methods, dielectrometry, and ultrasonic methods. Author

Aastra Advanced Ceramics is a major manufacturer of piezoelectric ceramic materials. Aastra Aerospace is involved in the development of smart structures technology based on these materials. Piezoelectric ceramics as actuators offer high mechanical stiffness, large output stress, and good linearity. As strain sensors, piezoceramics offer very high sensitivity. Initial research into the use of externally-bonded or embedded piezoceramic strain sensors and actuators has lead to the development of in-line sensor-actuator systems for use in truss-type smart structures. The target applications for these units are large flexible space structures, but the technology is applicable to earth-based truss structures as well. Similarly, Aastra is investigating the use of piezoelectric materials for the active damping of aircraft structures, with the goal of reducing structure-borne cabin noise with minimum additional weight. The development of Aastra's piezoceramic research activities and an overview of present work in the field of smart structures is presented. Author (revised)

Structurally integrated fiber optic sensors (SIFORS) will form a necessary part of future Smart Structures and strain sensing will provide valuable information on the use and loading of such structures and also determine the response of the structure to these loads. Strain measurements may be used to check structural integrity and in the case of Smart Adaptive Structure they would provide the deformation information required by the structurally integrated actuation control system. Continuous monitoring of the applied loads could also be used to determine the actual fatigue life of the structure at any point in its operation. In the case of composite materials improved quality control during fabrication may be possible from such a built-in sensing system and this could lead to a more consistent and reliable product. Overall the introduction of an embedded fiber optic strain sensing system to composite structures may enhance confidence in their use and lead to an expansion in the range of application, especially as primary structures in the aerospace field. The types of fiber optic sensors are reviewed and it is shown that the intracore Bragg grating and the intrinsic Fabry-Perot interferometer appear to qualify for continued consideration as the universal sensor for the broad range of potential Smart Structures. The key elements of strain sensing with both types of structurally integrated fiber optic sensors are reviewed and issues such as thermally induced apparent strain are discussed. It is shown that although both sensors now have good methods of demodulation, the Bragg grating sensor has the greatest potential to satisfy the requirements demanded of the ideal sensor for Smart Structures due to the recently developed radiometric wavelength demodulation system. This system promises the fabrication of a robust, simple, absolute measurement, low cost multisensor system that could be integrated onto an optoelectronic chip that can form part of the interface to any structure and in essence solve the critical interconnect problem. Two important questions, however, remain to be addressed: can the intracore Bragg grating sensor perform all of the tasks required, and can Bragg gratings of 'sufficient quality' be fabricated in an automated process. Shape memory materials form one group of 'smart materials' which are of current interest. The sensing and actuating performance of these shape memory materials have been used in diverse industrial applications. These applications involve either the one-way or two-way effect, pseudoelasticity, recovery forces or damping characteristics of the SM-alloy. Each of these characteristics is associated with its unique response to thermal-mechanical forces. Besides these material parameters, the operating conditions and design parameters have to be taken into account when structures, in which SM elements are incorporated, are to be considered. The processing as well as subsequent operating conditions are relevant to the reproducible (stable) behavior and life time of the material and are discussed. Author (revised)

Shape memory alloy wire 'tendons' can be used as embedded actuator elements to control the level of facesheet strain in adaptive structural components which utilize sandwich panel construction. As facesheet strain is varied, the degree of curvature and magnitude of tip deflection of a panel section can be controlled. Methods for modeling and conditioning shape memory materials and their subsequent integration into composite structures are described

along with related control system and feedback sensor development. Finally, an adaptive antenna application employing 'flex-biased' actuation and an attitude control surface based on 'antagonistic' actuation are described. Author (revised)

Composite materials offer tremendous benefits for engineering applications and are now specified for use in several safety critical structures. However, despite extensive materials research and development, they do have a number of areas where their behavior is still not fully understood. This is particularly so with the more complex mechanical parameters in larger structures. Current structural design attempts to allow for these unknowns by over-designing, extensive testing, and frequent inspection. Embedded optical fiber sensors offer the potential to monitor many of these parameters, and are additionally of a similar physical and mechanical nature to the reinforcement fibers used in advanced composites. Westland Aerospace was involved in the development of fiber sensors for composite monitoring for over five years, and pioneered the application of embedded fiber sensors in thermoplastic composites during earlier joint research projects with the United Technologies Research Center. Previous programmers showed that research and development into both optical fiber sensors and materials is a key to the success of 'smart structures' technologies. The BRITE sponsored Optical Sensing Techniques in Composites (OSTIC) program represents the largest European research program to date. Similar research is underway at several centers worldwide, mainly in the USA and Canada. It was decided to set up a joint sensors/materials project under the UK Government supported LINK Structural Composites collaborative research program. The project will be performed by Westland Aerospace and the Optical Fibre Sensors Group at the UK Optoelectronics Research Centre. Factors relating to the development and application of optical fiber strain sensors for the monitoring of composite structures, and in particular the factors relating to the embedding of these optical fibers in composite laminates are addressed. The requirements of a fiber-optic strain sensor system for aircraft smart structures are outlined, and an experimental system developed by Canadian Marconi Company for this application is reported. Fiber-optic strain sensors were mounted on an aircraft undergoing full-scale durability and damage tolerance tests, the results of which are presented. Tests were also carried out to verify the response of fiber-optic sensors to acoustic impulse signals. Input signals, similar to the ones encountered in damaged materials under stress, were used to evaluate the response of the sensor to bulk, surface, and plate waves. This was done in order to assess the performance of fiber-optic sensors employed in the acoustic detection of damage in materials.

For several years, the Air Force Wright Laboratory has been investigating smart structures technologies. Smart structures incorporate active materials into structural components. Active materials either sense their environment or change in response to an external stimulus or both, and also should be able to carry loads. A smart structure is thus capable of sensing and/or reacting to its environment. Smart structures research at Wright Laboratory has mainly concentrated on aircraft sensory structures and multi-functional structures, such as integrated antennae (i.e., smart skins). Several major programs were initiated to apply and demonstrate these technologies. Recently, the ability of active materials (piezoceramics, for example) to control aircraft structures for improved performance and longevity, has received attention as well. The smart structures technologies are categorized as sensory, active, or multi-functional. The current state of the art for each area and programs aimed at exploiting smart technologies for aircraft applications are described. Gaps in the current technology are identified. It will be shown how use can be made of piezoelectric elements, integrated as sensors and actuators in a closed control loop, to improve the modal damping behavior of elastomechanical systems. Focus is pointed on some special characteristics of piezoelectric elements, such as their dynamic behavior, their energy transfer capabilities when being used as actuators, and their geometric filtering possibilities when being used as sensors. The experimental part of the work concentrates on the active damping augmentation in the low frequency range of a flexible beam-shaped structural system with a total length of 4 meters. Silicon carbide reinforced titanium alloys or titanium aluminides are challenging materials for engine discs applications in the temperature range 650-800 C. The main problems concerning fiber-matrix compatibility, i.e. fiber coating degradation through diffusion controlled mechanisms and fiber-matrix mechanical behavior are reviewed based on recent studies. It is also shown how two micromechanical tests, the fragmentation and the push-out test may be correlated. With the help of a 1D shear-lag type model, taking fiber-matrix debonding into account, a good fit is obtained between measured and computed values of the fiber-matrix load-transfer mean shear-stress. Oxidation tests were performed on titanium aluminide alloys of three different compositions to determine their oxidation properties under isothermal and cyclic conditions. The TiAl/Ti3Al alloy and the Al3Ti exhibited roughly parabolic behavior between 900 and 1100 C, while the TiAl oxidized in a linear fashion. Rate constants and activation energies were calculated for each material, and based on these the rate-controlling processes and mechanisms were determined. Author

Titanium matrix composites (TMC's) are currently being developed for high strength and high stiffness applications with improved elevated operating temperature behavior. In order to provide guidelines for the development of new TMC's with the desired properties and to ensure reliable use, a thorough understanding of material behavior is required which necessitates the development and use of appropriate nondestructive evaluation (NDE) methods. This work outlines the concurrent use of NDE during composites development as well as material behavior studies of TMC's. The paper presents results based on various ultrasonic techniques developed in the Materials Directorate, Wright Laboratory of the U.S. Air Force for the evaluation of different aspects of development and use of TMC's to tailor the properties for a particular application. The paper presents the results of a limited test program to establish the mechanical behavior of titanium metal matrix composite (MMC) laboratory specimens under tensile, low cycle fatigue (LCF), and creep loading conditions at 600 C. Using a micromechanical model, finite element stress analyses have been undertaken to evaluate local stresses under the various loading conditions. Good agreement was obtained only after the inclusion of procedures to calculate the residual stresses induced in cooling from the composite consolidation temperature to the test temperature. Additionally, as part of a collaborative component evaluation study, model discs manufactured by Rolls-Royce plc have been subjected to spin testing. These LCF results have been correlated via a macromechanical model which accounts for the orthotropic behavior of the MMC reinforced region of the disc. Author

To date, the fatigue crack growth behavior of metal matrix composites (MMC) has been generally limited to data obtained from relatively small coupons (approximately 150 mm x 25 mm). Although self similar crack growth has been observed in some cases, many observers have noted various complex crack growth phenomena. Behaviors such as fiber bridging and extensive crack branching have been reported in several papers. The purpose of this paper is to present the results of several static and crack growth tests on larger titanium based MMC center cracked coupons (406 mm x 63.5 mm). The use of larger specimens has allowed for more observations during stable crack growth and is much more representative of actual applications. Author

Recent work on the prediction of optimal processing and material characteristics for improved fatigue behavior of metal and intermetallic matrix composites (MMC's/IMC's) is summarized. The method is incorporated into the MMLT (Metal Matrix Laminate Tailoring) code. Excellent correlations between predictions for the isothermal fatigue life of the SCS-6/Ti-24Al-11Nb composite and experimental data are obtained at various temperatures and stress ranges. Finally, the optimal processing conditions for improved isothermal fatigue life of the composite are evaluated and the attained isothermal fatigue life improvements are shown. Author (revised)

where these materials could be used to reduce weight or improve performance. This workshop on the subject of characterization of titanium composites was intended to provide a forum for the exchange of information in this important area. Characterization in this case refers to the understanding of the behavior of the composites as it relates to the ability to predict their performance in real-life applications. It covers various topics that include mechanical test techniques, NDE methods, life prediction models, and other factors that will affect the level of confidence with which these relatively new materials will be accepted for application. For individual titles, see N94-36650 through N94-36670.

High-temperature, light-weight materials represent enabling technology in the continued evolution of high-performance aerospace vehicles and propulsion systems being pursued by the U.S. Air Force. In this regard, titanium matrix composites (TMC's) appear to offer unique advantages in terms of a variety of weight-specific properties at high temperatures. However, a key requirement for eventual structural use of these materials is a balance of mechanical properties that can be suitably exploited by aircraft and engine designers without compromising reliability. An overview of the current capability of titanium matrix composites is presented, with an effort to assess the balance of properties offered by this class of materials. Emphasis is given to life-limiting cyclic and monotonic properties and the roles of high-temperature, time-dependent deformation and environmental effects. An attempt is made to assess the limitations of currently available titanium matrix composites with respect to application needs and to suggest avenues for improvements in key properties. Author

Titanium Matrix Composites have long been known to offer potential for use in aeroengine components. The cost of producing the fiber and fabricating components has delayed large scale developments because of concern over long term component costs. The slow development pace has, in turn, kept the fiber and composite price high through low demand. Composite manufacturing routes using foil and filament wound fiber has been used for many years. The difficulties of maintaining a suitable fiber distribution during hot isostatic pressing and the availability of cheap foil have effectively put this technique on the shelf. However excellent fiber distributions have been achieved even in difficult geometries by a BP proprietary process. Mechanical properties comparable with the most expensive routes can be achieved with this, one of the cheapest manufacturing routes. Author

SiC-fiber reinforced titanium alloys (Ti6A14V and IMI834) were processed by fiber coating and hot isostatic pressing (HIPing). Composites with a well consolidated microstructure, with a fiber volume fraction between 0.2 to 0.6, with a narrow fiber distance distribution and a fine globular grain structure were obtained. Tensile properties according to the rule of mixture are measured with values of the ultimate tensile strength for the 0.4 SiC-Ti6A14V-composite of 2.4 GPa at room temperature and for the 0.37 SiC-IMI834-composite of 1.3 GPa at 900 C. Fatigue properties were measured under loading conditions of R = -1. Different crack initiation effects for different matrix properties and stress amplitudes were observed. Author

The thermomechanical behavior of continuous-fiber reinforced titanium based metal-matrix composites (MMC) is studied using the finite element method. A thermoviscoplastic unified state variable constitutive theory is employed to capture inelastic and strain-rate sensitive behavior in the Timetal-21s matrix. The SCS-6 fibers are modeled as thermoplastic. The effects of residual stresses generated during the consolidation process on the tensile response of the composites are investigated. Unidirectional and cross-ply geometries are considered. Differences between the tensile responses in composites with perfectly bonded and completely debonded fiber/matrix interfaces are discussed. Model simulations for the completely debonded-interface condition are shown to correlate well with experimental results. Author

This review paper considers the experimental characterization of crack growth from unbridged defects in fiber reinforced titanium metal matrix composites subjected to cyclic loading by the use of fracture mechanics parameters. The conditions under which parameters such as the nominal applied stress intensity range, Delta-K(sub app), the nominal maximum stress intensity factor, K(sub max), and the effective stress intensity range, Delta-K(sub eff), are of use, and their experimental measurement are considered. Effects of fiber fracture, stress intensity factor range, mean stress, loading configuration (bending versus tension), test temperature, and fiber-matrix interfacial strength on fatigue crack growth resistance are highlighted. Finally, a possible approach to the prediction of crack arrest in such composites is outlined.

This paper presents an experimental and analytical evaluation of cross-plied laminates of Ti-15V-3Cr-3Al-3Sn (Ti-15-3) matrix reinforced with continuous silicon-carbide fibers (SCS-6) subjected to a complex TMF loading profile. Thermomechanical fatigue test techniques were developed to conduct a simulation of a generic hypersonic flight profile. A micromechanical analysis was used. The analysis predicts the stress-strain response of the laminate and of the constituents in each ply during thermal and mechanical cycling by using only constituent properties as input. The fiber was modeled as elastic with transverse orthotropic and temperature-dependent properties. The matrix was modeled using a thermoviscoplastic constitutive relation. The fiber transverse modulus was reduced in the analysis to simulate the fiber-matrix interface failures. Excellent correlation was found between measured and predicted laminate stress-strain response due to generic hypersonic flight profile when fiber debonding was modeled. Author

This paper presents work on development of test techniques for S-N fatigue, fatigue crack growth, and fracture toughness of titanium matrix composites. Work has concentrated on eight-ply unidirectional Ti-6-4/SM1240 from BP Metal Composites with some preliminary work on eight-ply unidirectional Ti-6-4/SCS-6 from Textron Speciality Materials. For S-N fatigue testing, an approach, used successfully for the Textron material, consistently gave failures in the tab region for BP material. Transverse fracture toughness of Ti/SiC sheets has been determined using a double cantilever beam test. Care has to be taken to restrain specimen twisting. For two BP materials, the transverse fracture toughness correlated with the static strength values. Author

Titanium matrix composites (TMC's) are being considered for a number of aerospace applications ranging from high performance engine components to airframe structures in areas that require high stiffness to weight ratios at temperatures up to 400 C. TMC's exhibit unique mechanical behavior due to fiber-matrix interface failures, matrix cracks bridged by fibers, thermo-viscoplastic behavior of the matrix at elevated temperatures, and the development of significant thermal residual stresses in the composite due to fabrication. Standard testing methodology must be developed to reflect the uniqueness of this type of material systems. The purpose of this paper is to review the current activities in ASTM and Versailles Project on Advanced Materials and Standards (VAMAS) that are directed toward the development of standard test methodology for titanium matrix composites.

The performance objectives proposed for the next generation of military engines (thrust/mass ratio approximately equals 15) suggest extreme conditions of usage of titanium alloys in the compressor discs, while not allowing any consideration for the mass objectives. The composite materials with metal matrices (titanium base matrix reinforced by long fibers of silicon carbide) exhibit characteristics that appear to be encouraging for the construction of compressor discs (rigidity, endurance at high temperature). A complete understanding of the characteristics of fiber reinforced titanium matrix composites is a qualifying condition to the initiation and to the validation of calculation methods on the expected life of the components. The first step is to study their conduct, on laboratory samples, while in a state of traction or oligo-cyclic fatigue. The elements leading to the development of the tests are presented. A review is given on some aspects of designing with continuous fiber reinforced titanium alloys. Issues that are addressed are as follows: (1) Need for multiaxial constitutive relations describing behavior of fiber reinforced titanium for monotonic loading at different temperatures, unloading at different temperatures, cyclic changes in load and temperature both in and out of phase, and general thermomechanical loading. Linear, yielding, incremental plasticity and time dependent deformations are considered. (2) Need for reliable failure criteria that take account of the micromechanisms that contribute to the failure event. (3) Role that micromechanical modeling can play in the development of reliable constitutive relations and design methods. (4) Need for validated test methods to measure the parameters that appear in the constitutive relations that are used for design purposes.

The goal of this paper is to present work related to the development (study, fabrication, qualification) of a box and a bonnet cover out of composite materials intended for airborne electronic equipment on fighter aircraft. Work was undertaken with a double objective: assess mass characteristics compared to a metal case and obtain equivalent electromagnetic shielding performance. The technological step is presented: choice of materials and the processes of fabrication, mechanical and electromagnetic dimensioning. The methods of manufacture are described; they made it possible to obtain the desired characteristics. The metal composite material elements are currently being used on fighter aircraft.

The ever increasing demand in technical and economical performances improvement of aircrafts has a direct incidence for avionics. Except microelectronic integration, the enclosures have a high potential of evolution. The main advantages of composite materials over metals in forming electronic enclosure are: reduction of weight (minimum 30 percent), better resistance to corrosion, improved fatigue and impact resistance, achievement of complex shapes, and low coefficient of thermal expansion. The main problems to be solved in extending the application of the use of composite materials to the field of airborne electronic equipments are to: provide adequate electromagnetic shielding, ensure survival in harsh thermal and mechanical environments, and achieve global competitivity of the final products. Different technologies have been considered: injection molding of short fibers reinforced thermoplastic for small sized equipments (V less than 21), pressure molding of graphite and glass reinforced thermosets for ATR case families, and metal matrix composites. This paper will address the main investigations that have been undertaken in France since 1986 in the first two fields covering both manufacturing and evaluation results.

This article reports our recent progress in the modeling of turbulent combustion for propulsion applications. The description of the reactive flow relies on the flamelet concept and uses a transport equation for the flame surface density. The coherent flamelet description which has evolved from a series of numerical and experimental studies is first reviewed and its recent improvements are explained. We then focus on the premixed version of the model. Two applications of relevance to aeronautical propulsion are then described. The first concerns a flame stabilized by a hot stream of combustion products. The second deals with a ramjet configuration comprising two lateral injection jets. In both cases, the model predictions are compared with experiments. It is shown that the model provides viable representations of these two cases.

The influences of flow rate, fuel air ratio, and bluff body geometry on the predominant frequencies of combustion-driven oscillations were measured in a tube and disc combustor. Small shifts in major frequencies were observed for different stabilizer geometries. By changing mass flow rate and at high velocities by changing the F/A ratio, discrete jumps in the frequency of large amplitude oscillations were produced in some of the configurations. Measurements of the wall pressure oscillations amplitude along the cold duct, upstream from the flameholder, confirm the presence of an acoustic three quarter wave. Changes in the cold cut length implies a difference in the main frequency of the pressure oscillations spectrum that was found to agree with the difference between two acoustic 3/4 waves corresponding to the two tube lengths.

The conference proceedings contains 38 papers that cover new technologies for low NO(x) combustors and advanced high pressure/high temperature cycle engines. The technical evaluation report and the keynote address are included at the beginning,

and discussions follow most papers. The symposium was arranged in the following sessions: technology overview papers (two papers); modeling: pollutant formation (four); modeling: combustor design (five); high temperature fuels and fuel systems (six); combustion research: performance (six); combustion research: emissions (five); fuel atomization: diagnostics and modeling (five); and combustion research: flowfield and mixing (four). The last paper is a contribution from Russia not allocated to a session. For individual titles, see N94-29247 through N94-29285.

The challenges in designing high performance aircraft combustion systems have not changed significantly over the years, but the approach has shifted towards a more sophisticated analytical process. Initially an overview of the U.S. Navy's component technology development procedure is presented to show how technology development is still tied into mission requirements. A more technical discussion on combustion technology status and needs will show that the classic impediments that have hampered progress towards near-stoichiometric combustion still exist. Temperature rise, mixing, liner cooling, stability, fuel effects, temperature profile control, and emissions continue to confront the aerodynamic and mechanical designers with a plethora of engineering dilemmas and trade-offs. In addition, new materials such as ceramic matrix composites (CMC) and intermetallics like titanium aluminides (TiAl) are now being incorporated into every advanced design. The process of combustion design has taken on a new meaning over the past several years as three dimensional codes and other advanced design and validation tools have finally changed the approach from a 'cut and burn' technique to a much more analytical process. All of these new aspects are now integral elements of the new equation for advanced combustion design that must be fully understood and utilized. Only then will the operable, high temperature capable combustion systems needed for future military aircraft be developed. Author

Even with it's marginal performance, Concorde has demonstrated that supersonic civil aircraft are a practical proposition. A second generation machine will need sufficiently good performance for a robust operating system that can provide reliable, frequent service with competitive economics. Additionally, the propulsion system must be acceptable environmentally. That is it must create acceptable noise levels around airports and have acceptable emissions throughout its mission including cruise. Whatever devices may be used to improve the acceptability at subsonic flight conditions, the high operating temperatures at cruise can create difficult targets for the operation of the combustion system both mechanically and in the combustion process itself. While the driving force is ever better fuel consumption and weight to achieve economic viability, a future supersonic transport engine will have cycle temperatures limited only by the mechanical integrity of the major components. The environment of the major components in modern gas turbine engines is dominated by the air delivered by the compressor system. Consequently the maximum compression temperature is governed by materials available for the turbine and compressor discs. The continued improvement of the disc material leads to combustion inlet temperatures beyond today's experience and sets difficult targets for combustion system emissions. This is worsened by the requirement being at cruise and therefore maintained for the major part of the mission. Problems such as creep and oxidation of metallic parts are also considered. PREDICTION OF PROMPT NO(X) IN HYDROCARBON AIR FLAMES

VALERIE DUPONT, M. POURKASHANIAN, and A. WILLIAMS *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines 13 p (SEE N94-29246 08-25) Sep. 1993

(AGARD-CP-536) Copyright Avail: CASI HC A03/MF A04

The gas turbine industry is directing particular attention to very low NOx combustors, whether for aircraft or land based CCGT systems. These low NOx combustors frequently use liquid fuels or natural gas burning under very lean premixed conditions with air or under rich-lean conditions, although only the first case is studied here. In land based systems, diluted steam or nitrogen are sometimes injected into the combustion chambers to reduce flame temperature. The NOx emissions from such systems are the product of three chemical mechanisms which are interrelated: the hydrocarbon prompt NO, the thermal NO (extended Zeldovich mechanism), and the nitrous oxide route to NO. Formation of NO2 from NO also occurs, as well as emission of carbon monoxide and unburnt hydrocarbons. When the fuel-oxidant proportion decreases towards leaner conditions, flame temperatures are lowered, resulting in the total NO being reduced and the thermal-NO contribution greatly diminished to the benefit of the remaining two mechanisms of NO formation. While knowledge of the elementary reactions and their chemical kinetics concerning methane and simple hydrocarbons combustion has existed for a number of years, its use for computer modeling is limited to simple flow dynamics configurations. Nevertheless, understanding of such combusting flows under a wide range of experimental conditions allows for analogies or speculations with more complex actual systems. Such understanding can be achieved by means of one dimensional laminar premixed flame modeling, with a full chemical mechanism which incorporates the three routes of NO formation. Complementary to this understanding is the modeling of the actual combustion system using a full description of the fluid dynamics coupled with a reduced chemical scheme, which is then compared against the first model. The objective of this investigation is to evaluate the relative importance of the three mechanisms of NO formation in lean premixed methane-air combustion with increasing pressure using the one dimensional plug flow package PREMIX, and to test the validity of a three dimensional model with a global chemical mechanism against the one dimensional model in the atmospheric pressure case. Methane is chosen because it is the only mechanism which is reasonably well known and is a good guide to the behavior of other hydrocarbons. The mixture ratio chosen is richer than that in lean gas turbines, but the combustion of this mixture with the low preheat gives realistic gas turbine final flame temperatures. Conditions of NO2 formation are also analyzed in the one dimensional model and results extrapolated to the case of gas turbines. Derived from text

An extension of a flame surface density model, combining flamelet concepts and homogeneous reactor combustion, is proposed to predict NO and CO formation. Results for CO in propane-air premixed flames for different equivalence ratios are compared to available experimental measurements. The agreement is good but the model is sensitive to the determination of the flamelet model parameters such as those governing the effective strain rate. Author (revised)

CFD predictions of nitric oxide and smoke production in a tubular combustor are described for a range of inlet temperature and pressure conditions up to 800 K and 8 bar, chosen to distinguish the effects of both state properties and turbulence on formation rates. Combustion models based on both laminar flamelet and chemical equilibrium representations are contrasted and compared with measurements in the literature. While uncertainties persist with respect to the detailed mechanisms, notably for soot formation, a strategy is identified which extends the role of mixture fraction in the calculation of the influence of turbulent scalar fluctuations on emissions prediction. Soot formation is an important but poorly understood subject. Although significant advances have been made in the last few years, soot formation models for numerical calculation still present recognized shortcomings. Different soot formation models are compared in the calculation of a propane turbulent diffusion flame and the influence of soot agglomeration and refractive index on soot volume fraction values inferred from extinction measurements are investigated. The time-averaged equations governing conservation of mass and momentum are closed by the k-epsilon eddy viscosity/diffusivity model and combustion is modeled using the laminar flamelet approach. Soot prediction involves the solution of transport equations for soot particle number density and soot mass fraction. The uncertainties of soot volume fractions obtained from extinction measurements due to agglomeration and the value of the complex refractive index were studied. Results using Rayleigh approximation were compared with predictions using the model presented by Iskander et al. for scattering and extinction of light by an ensemble of spherical particles. THE EFFECT OF INCOMPLETE FUEL-AIR MIXING ON THE LEAN LIMIT AND EMISSIONS CHARACTERISTICS OF A LEAN PREVAPORIZED PREMIXED (LPP) COMBUSTOR

D. A. SANTAVICCA, R. L. STEINBERGER, K. A. GIBBONS, J. V. CITENO, and S. MILLS *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines 12 p (SEE N94-29246 08-25) Sep. 1993 Sponsored by NASA. Lewis Research Center and GE

(AGARD-CP-536) Copyright Avail: CASI HC A03/MF A04

Results are presented from an experimental study of the effect of incomplete fuel-air mixing on the lean limit and emissions characteristics of a lean, prevaporized, premixed (LPP), coaxial mixing tube combustor. Two-dimensional exciplex fluorescence was used to characterize the degree of fuel vaporization and mixing at the combustor inlet under non-combusting conditions. These tests were conducted at a pressure of 4 atm., a temperature of 400 C, a mixer tube velocity of 100 m/sec and an equivalence ratio of .8, using a mixture of tetradecane, 1 methyl naphthalene and TMPD as a fuel simulant. Fuel-air mixtures with two distinct spatial distributions were studied. The exciplex measurements showed that there was a significant amount of unvaporized fuel at the combustor entrance in both cases. One case, however, exhibited a very non-uniform distribution of fuel liquid and vapor at the combustor entrance, i.e., with most of the fuel in the upper half of the combustor tube, while in the other case, both the fuel liquid and vapor were much more uniformly distributed across the width of the combustor entrance. The lean limit and emissions measurements were all made at a pressure of 4 atm. and a mixer tube velocity of 100 m/sec, using Jet A fuel and both fuel-air mixture distributions. Contrary to what was expected, the better mixed case was found to have a substantially leaner operating limit. The two mixture distributions also unexpectedly resulted in comparable NO(x) emissions, for a given equivalence ratio and inlet temperature, however, lower NO(x) emissions were possible in the better mixed case due to its leaner operating limit. A prime requirement in the design of a modern gas turbine combustor is good lean blowout (LBO) stability to ensure an adequate stability margin. Therefore, a geometrically simple, optically accessible, and acoustically decoupled research combustor was designed to reproduce the gross features of the flow field in a modern annular gas turbine combustor. Its LBO was measured using methane and propane fuels. We successfully observed and documented a systematic and detailed sequence of events comprising an attached flame, a lifted shear flame, an intermittent shear flame, the large-scale instability of the flame front, and LBO. Also, for the sake of comparison, a generic gas turbine combustor was tested and its LBO limits were measured. We found that LBO in the research combustor behaved like a perfectly stirred reactor (PSR) for values of combustor-loading spanning three orders of magnitude. Also, LBO was successfully correlated using a simple PSR theory. Finally, Swithenbank's dissipation gradient approach and an eddy dissipation model with a built-in characteristic extinction time criterion, when coupled with CFD, offer the possibility of an a priori calculation of LBO. The lean stability of a generic gas turbine combustor at peak heat release rates was less than that in a research combustor. Also, in the generic combustor, the flame changes from a lifted to an attached position depending upon how combustor loading is achieved. Due to such complications, modeling of the LBO process that works reasonably well with the research combustor will be seriously challenged by the blowout behavior evidenced in the generic gas turbine combustor. The first results of a research and development program on combustion characteristics of gaseous hydrogen fuel in a 'can' type gas turbine combustor, both in combination with air or with oxygen and water, are here presented. Application of a H2/O2/H2O combustion chamber is suggested for the launch-boost phase of an advanced turboramjet. Experiments have been conducted to determine the configuration and the operation of the hydrogen-air combustion chamber test facility, to be transferred to two different kinds of small power turboshafts. Computations, project details and tests, are presented regarding high pressure and temperature stoichiometric H2/O2 combustion in which water is gradually injected. Referring to an already realized and operated (on behalf of the author) H2/O2/H2O combustor for a water steam closed cycle in a turbine/alternator electrically propelled automobile, a detailed design is developed for a quite higher steam temperature, as required in high performance boost phase of a low noxious emission advanced turboramjet, in which H2 and O2 are stored in liquid form. Conventional and advanced gas turbine engines are coming under increased scrutiny regarding pollutant emissions. This, in turn, has created a need to obtain in-situ experimental data at practical conditions, as well as exhaust data, and to obtain the data in combustors that reflect modern designs. The in-situ data are needed to (1) assess the effects of design modifications on pollutant formation, and (2) develop a detailed data base on combustor performance for the development and verification of computer modeling. This paper reports on a novel high pressure, high temperature facility designed to acquire such data under controlled conditions and with access (optical and extractive) for in-situ measurements. To evaluate the utility of the facility, a model gas turbine combustor was selected which features practical hardware design, two rows of jets (primary and dilution) with four jets in each row, and advanced wall cooling techniques with laser drilled effusive holes. The dome is equipped with a flat-vaned swirler with vane angles of 60 degrees. Data are obtained at combustor pressures ranging from 2 to 10 atmospheres of pressure, levels of air preheat to 427 C, combustor reference velocities from 10.0 to 20.0 m/s, and an overall equivalence ratio of 0.3. Exit plane and in-situ measurements are presented for HC, O2, CO2, CO, and NO(x). The exit plane emissions of NO(x) correspond to levels reported from practical combustors and the in-situ data demonstrate the utility and potential for detailed flow field measurements. Author

As part of an ongoing program of continuous improvement by control of gaseous emissions from the combustors of gas turbines, a unique fuel-staged annular combustor is being developed for application to current and future Pratt & Whitney aircraft engines. The configuration advantages of this combustor are outlined, and discussions are presented on staging considerations and fuel system impacts. Development of the fuel-staged combustor is described by reference to supporting mixing experiments and computational fluid dynamic studies, and rig tests at high pressures. Measured results are given appropriate for the International Aero Engines (IAE) V2500 engine that show progressive reductions in achieved emissions compared to the goals established for this program. The pollutants emissions decrease doesn't seem easily achievable, particularly with advanced engines cycles conditions with high pressure, temperature, and fuel to air ratio. For a given fuel and air split, the combustor size can't be reduced without leading to relight altitude, combustion stability, and emissions concerns. In addition, the liners areas to be cooled remain considerable, the cooling airflow increase leads to higher fuel to air ratio in the primary zone and finally to unacceptable Nox emissions levels due to higher flame temperatures. In order to satisfy the trade off in between the combustor performance at low and high engine ratings, several combustor concepts are in development. Among them, the use of variable geometries to modulate the primary zone airflow seems promotive. Indeed, this concept allows to satisfy the compromise between the different ratings taking into account the decrease of the combustor panels areas to be cooled. That is the reason why this variable geometry concept is particularly suitable to high pressure and temperature engines cycles. In this paper, test results recorded on a five-cups sector fitted with a variable geometry injection system, and some measured performance on a full annular combustor are commented. It appeared that acceptable performance in term of combustion stability can be met with a low volume combustor. The cooling airflow reduction and the primary zone fuel to air ratio control allow to meet quite good and homogeneous combustor exit temperature profiles whatever the engine rating. Author

This paper summarizes the work undertaken by the Defense Research Agency (DRA Pyestock) for the BRITE/EURAM Low Emissions Combustor Technology Project No 1019. The work was jointly funded by the CEC (DGXIIH), the UK DTI (CARAD - ATF4) and the UK MOD (DCSA). The gas turbine emissions problem is summarized and the design philosophy of the experimental program is described. The principal objective was to demonstrate a simultaneous reduction of NO(x) and smoke emissions together with acceptable idling emissions and stability in an unstaged combustor. A secondary objective was to demonstrate the extent to which NO(x) and smoke could be reduced if the combustor was to be used as the main stage of a staged combustor where a poorer idling performance could be accepted. The work consisted of a parametric investigation of the principal factors controlling the emissions produced in the combustor primary zone. Particular emphasis was placed on the influence of the distribution, number, and size of air entry holes and of residence time on pollutant formation. The results from the complete experimental program are summarized. These suggest that NO(x) reductions of about 30-40 percent should be possible together with excellent smoke and idling performance. The results suggest that NO(x) was formed very close to stoichiometric flame temperatures even at very weak combustor mixture strengths and under well mixed conditions. The reductions that were achieved were largely as a result of reductions of residence time. Author

This paper presents an experimental work on the control of pollutants produced in a tubular hydrocarbon fueled combustor, by the injection of hydrogen in small quantities (less than 4 percent of total fuel). Hydrogen is introduced in the primary zone premixed with the air. Using this technique, with lean primary zone, it is possible to reduce the NO(x) emission level while maintaining CO and HC emission index at normal levels (CO and HC levels are greater without hydrogen injection). Injecting butane, instead of hydrogen, shows that there is no beneficial effect, so the influence of hydrogen in CO and HC reduction is due mainly to factors such as hydrocarbon substitution and chemical kinetics. An analysis to estimate the contribution of these factors is also included.

Reaction progress in premixed methane-air flames in round ducts without and with kerosene sprays has been quantified on the basis of species concentration measurements for different fueling arrangements of kerosene with equivalence ratio, proportion of liquid to gaseous fuel, duct length and air preheat temperature as variables in smooth and in rough combustion. The intensity of heat release close to the flame holder in rough combustion was greater than that in smooth combustion, and the duct length necessary to ensure complete combustion decreased with air preheat temperature and upstream turbulence intensity and was weakly dependent on the proportion of methane to kerosene in flow arrangements where the kerosene was sprayed upstream of the flame-holder. The injection of kerosene through the flame holder at a velocity larger than that of the mean flow past the disk led to uneven mixing and incomplete combustion. Pulsed injection of kerosene through a pintle-type injector also resulted in incomplete combustion due to the larger droplet size than in arrangements with a steady flow of kerosene. Oscillations of large amplitude were induced at equivalence ratios usually associated with smooth combustion and oscillations in rough combustion ameliorated by pulsed injection of kerosene comprising around 10 percent of the total fuel. The next generation of commercial aircraft will include turbofan engines with performance levels significantly better than those in the current fleet. Control of particulate and gaseous emissions will also be an integral part of the engine design criteria. These performance and emission requirements present a technical challenge for the combustor: control of the fuel and air mixing and control of the local stoichiometry will have to be maintained much more rigorously than with combustors in current production. A better understanding of the flow physics of liquid fuel spray combustion is necessary. This paper describes recent experiments on spray combustion where detailed measurements of the spray characteristics were made, including local drop-size distributions and velocities. Also, an advanced combustor CFD code has been under development and predictions from this code are compared with experimental results. Studies such as these will provide information to the advanced combustor designer on fuel spray quality and mixing effectiveness. Validation of new fast, robust, and efficient CFD codes will also enable the combustor designer to use than as valuable additional design tools for optimization of combustor concepts for the next generation of aircraft engines. This paper presents experimental results, numerical models, and simulations relating to the behavior of the liquid phase in combustion chambers. These studies concern the initial conditions, boundary conditions, and validations of the models of the various physical processes which must be integrated into the computer codes of reactive flows. Several experiments are presented: characterization of a jet of drops at the aerodynamic exit of a burner, dispersion of the drops in a screen turbulence and a strongly nonstationary flow, trajectories and evaporation of the drops in a turbulent flow, and interaction of the drops with a hot wall. The characterizations of the diphasic flows are carried out by LDA and hot wire for the gas phase and by phase Doppler anemogranulometry and rapid video techniques associated with image processing for the liquid phase. Video techniques and image processing make it possible to restore the trajectories of the drops, their speed as well as the main statistics of dispersion (average trajectory, envelope, and presence rate). The experimental results, in particular those coming from the dispersion of the drops, are compared with the numerical results of simulations. The Lagrangian method is used for transport of the drops, and their dispersion can be calculated starting from the following two approaches: the gas phase is calculated by direct simulation and a deterministic model is retained for the transport of the drops; and the gas phase is calculated starting from a model of turbulence of the type K- and stochastic models are used for the transport of drops. In conclusion, the models most appropriate to the diphasic flows studied are deduced. Author (revised)

A NEW EULERIAN MODEL FOR TURBULENT EVAPORATING SPRAYS IN RECIRCULATING FLOWS
S. WITTIG, M. HALLMANN, M. SCHEURLEN, and R. SCHMEHL *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines 11 p (SEE N94-29246 08-25) Sep. 1993 Sponsored by Arbeitsgemeinschaft Hochtemperatur Gasturbine and DFG
(AGARD-CP-536) Copyright Avail: CASI HC A03/MF A04

A new Eulerian model for the computation of turbulent evaporating sprays in recirculating flows is derived. It comprises droplet heating and evaporation processes by solving separate transport equations for the droplet's temperature and diameter. Full coupling of the droplet and the gaseous phase is achieved by the exchange of source terms due to momentum, heat, and mass transfer. The partial differential equations describing the droplet's transport and evaporation in the new method can be solved using the same numerical procedure as for the gas phase equations. The validity of the model is established by comparison with a well known Lagrangian approach and with experimental data. For this purpose calculations of a recirculating droplet charged air flow within a model combustor are presented. Author (revised)

The rich burn/quick quench/lean burn (RQL) combustion system is a potential concept to reduce both NO(x) and CO, UHC emissions. In view of the concept's crucial mixing process, an experimental investigation of a nonreacting multiple jet mixing with a confined crossflow has been conducted. Temperature distributions, mixing rate, and standard deviation were determined for measurements with round jet orifices by parametric variation of flow and geometric conditions. The results show that best mixing strongly depends on an optimum momentum flux ratio. Too high ratios yield a deterioration of mixing process, due to the mutual impact of opposed entraining jets. Furthermore, over a wide range of geometries investigated, inline and staggered configurations provide similar mixing rates. An appreciable enhancement of mixing with staggered orifice configurations only occurs for high momentum flux ratios and large spacings. Author

A small tubular combustor of normal design and behavior, employing acoustically controlled primary zone air-jet mixing processes, has been successfully tested at scaled 1/4 load operating conditions, and some data was obtained at 1/2, 3/8, and 3/4 loads. The acoustic control produced a distinct richening effect, measured just downstream of the primary zone, which produced a decrease in combustion efficiency and a somewhat increased and flatter combustion gas temperature distribution. The prime cause of richening was due to combustor flow blockage caused by acoustically enhanced jet penetration. This, and the secondary effect of acoustically shed jet toroidal vortices, resulted in up to 35 percent increase in mixing, relative to 'no-drive' measured just downstream of the primary zone. The acoustic drive produced a more uniform exit plane temperature pattern, resulting in up to 35 percent improvement in mixing relative to 'no-drive' and in up to 20 percent relative improvement in the temperature pattern quality. The effects depend on air/fuel ratio and, in general, improved relative to 'no-drive' with richening. At 3/4 load, 150 W single driver power, the acoustic driving effectiveness was reduced by about 80 percent with correspondingly reduced improvements in mixing and quality. The effects of acoustic drive were favorably controllable by means of the driving power, and the exit plane data showed increased flow blockage caused by increased jet penetration by the acoustic drive was the major control mechanism. Combustion theory is an applied science which is syntheses of several fundamental theories such as chemistry, heat and mass transfer theory, hydrodynamics, turbulence, etc. Now the knowledge of these theories is adequate to make calculations for practical purposes. However some difficulties still remain unresolved. The most important one is associated with the steep dependence of chemistry on temperature. As a result chemistry is confined to very thin zones (flamelets). Hence very large memory and speed of computers are needed to resolve flamelets in DNS. This difficulty is aggravated by the large number of intermediate species. The use of turbulence closures does not help since one has to assume that eddy diffusivities of reacting species and their pdf's (which are needed to average chemistry rates) are the same as that of conserved scalar. There are several examples indicating that these assumptions may lead to significant errors. Therefore there is a need to develop some new approach. Author

Recent advances in computer power have made it feasible to carry out Direct Numerical Simulation (DNS) of fundamental test problems in turbulent combustion. Nevertheless the requirements in terms of numerical grid resolution remain very severe and engineering computations will remain beyond the reach of DNS for some time to come. Thus there is an undiminished role for statistical modeling using traditional moment-closure techniques and DNS can be used to provide fundamental data in support of such modeling. The present paper describes a specific example of the use of DNS results to improve the quality of a well-established model of premixed turbulent combustion. A brief outline of the model formulation is given, followed by a short description of the DNS and post-processing techniques employed. Some results of immediate utility are presented in order to illustrate the usefulness of the approach, and the parameterization of some further data is discussed in detail. The significance of the main improvements to the modeling is indicated and some remaining limitations are discussed. The prospects for future model refinement by improved DNS are examined and found to be excellent. Author

Although most research and development effort in turbine alloys has been in the past directed towards the understanding and improvement of basic properties, it is a telling comment on the results that at present we can only manufacture the components with a reliability which, in the example case of a high pressure turbine disk, leads to a service life of less than one-fifth of the theoretical life of the alloy component. The purpose of this presentation is to examine the reasons for this situation and to indicate ways in which we can improve on it. We conclude that the techniques of melting, refining and casting which are now being developed have the potential to make a large change in the in-service life of turbine components without any significant change in the state of alloy development. Due to the ever-increasing demand for improvements in engine performance and better fuel efficiency, complex high pressure turbine (HPT) blade designs have been introduced into military engines. Greater emphasis has, therefore, been placed on increasing the structural integrity and life of engine components. Materials defects must be of a small enough size and sparse enough in population to enable the design of high thrust-to-weight ratio engines. This requirement has demanded the industry attainment of cleaner materials. In order to meet this requirement, possible process improvements were evaluated. Enhancements were incorporated into the melting and casting processes to reduce the size and number of dross defects within high pressure turbine blades. The accomplishment of this goal was through the efforts of a joint United States Air Force, Pratt & Whitney Task Force Team. Process implementation has been successful in reducing the remaining deleterious defects present in directionally solidified single crystal and polycrystalline nickel-base superalloy turbine blade materials. In conjunction with the introduction of melting and casting process improvements, the refinement of non-destructive inspection techniques was investigated. Author

The properties of aircraft engine discs made of a titanium and nickel alloy may be notably improved if deformations and temperatures are monitored during the forging process. On engines of recent fabrication, this optimization through thermomechanical treatment is also systematically applied. As an answer to this need SNECMA is using a monitoring system in its metal processing plant: monitoring devices positioned on the heat deformation machinery record and statistically document the important parameters. This new monitoring system, taking place at the time of fabrication, makes it possible to immediately detect any variance in the fabrication and to rapidly correct any possible abnormality. Thus checking and ensuring total duplication of the fabrication becomes systematic and the quality control checks on the finished project (strongly linked to the conditions of transformation) have improved. Finally, because of the knowledge that was thus gained on the forging process, our command of the thermomechanical treatments was improved. Variations in parameters which were not recorded in the past and had an important influence on the microstructure of the parts were observed. Transl. by FLS

By specific reference to the powder metallurgy alloy API the paper examines the role of defects in generating local residual stress fields. The effects of defect size and location on crack initiation and low cycle fatigue life are discussed. It is shown that at stress levels consistent with those experienced by current engine components, defects can act under cyclic loading as crack nucleators from cycle 1. Methods of calculating appropriate stress intensity factors are briefly reviewed and it is shown that at existing turbine disc operating temperatures, a linear elastic fracture mechanics stress intensity factor can be used to calculate crack growth rates. Finally, the major lifting methods used for aeroengine discs are briefly reviewed, and attention is drawn to the specific problems created by the presence of macrostructural defects. Author

An experimental technique is described that allows for the joint study of the kinetics and of the oxide structure during the high temperature oxidation of metal surfaces. Oxygen is supplied at the metal through an electrochemical oxygen pump and the oxygen pressure, at the metal surface, is measured during oxidation by a YSZ (yttria stabilized zirconia) oxygen sensor. XAS (x-ray absorption spectroscopy) is performed in fluorescence mode at the cation K edge and after each oxidation step. An appropriate analysis of the XAS spectra could provide information on both the oxidation kinetics and oxide structure. Experimental data on the high temperature oxidation of nickel, cobalt, and Fe(64%)Ni(36%) alloy, at low oxygen pressure, are reported and analyzed according to the proposed data reduction. These results indicate the presented technique to be particularly suitable for studying the hot corrosion of oxide film too thick for common surface spectroscopy (AUGER, ESCA) and too thin for conventional thermogravimetric technique. Ceramics have been considered over the last two decades as a possible alternative to refractory metals and alloys to be used as structural materials for aeronautical use. The main disadvantage of these materials is their brittleness and the very low value of the critical size of defects leading to fracture. The concept of ceramic matrix composites has been recognized as one of the ways to escape this difficulty. Extensive work has been performed to identify the mechanisms of crack propagation and general fracture for unidirectional composites, laminates or other fabrics, including the understanding of their long term response: creep

and fatigue effects or environmental degradation. The Workshop which has been held by AGARD SMP at Antalya (Turkey), April 1993, aimed at reviewing the present knowledge on all these aspects. For individual titles, see N94-24229 through N94-24240.

During the last decade, Ceramic Matrix Composites (CMC) have undergone a rapid development, and today, quite a number of composites are available. SiC/SiC and C/SiC, processed by Chemical Vapor Infiltration (CVI), are now produced on an industrial scale. C/SiC composites can currently operate at temperatures above 1600 C for propulsion applications on launchers and missiles. Other composites with oxide or silicon-nitride matrices are under development. The processing routes are moving from CVI to more cost-effective processes such as sol-gel and polymer precursor. These routes appear very promising since they currently use the technologies already developed for Organic Matrix Composites and carbon-carbon composites. The real challenge for these materials is in the areas of the working temperature, which must exceed 1600C, and the environmental behavior. To meet these requirements, new fibers with an increased thermal stability are under development. Author (revised)

Ceramic-and glass ceramic matrix composites are being touted for application in high temperature structural components. Before their potential can be realized, however, understanding of the significance of the fracture modes that occur at very low stress levels well beneath those commonly assumed to initiate microcracking in the literature, will be essential. Unfortunately, at this point in the technology development, the precise definition of these mechanisms, i.e., the geography of the fracture plane(s), has been described rather incompletely in experimental research. In most cases, the experimental observations only provide views of these cracks at their intersection with a surface of the composite. Thus, in this presentation, we will provide some predictions of failure scenarios based upon a hypothetical idealized initial flaw in the matrix-an annular crack in a plane normal to the fibers of an unidirectional composite. Although many of the properties needed for the modeling study have not been realistically determined, especially the in-situ strength/ fracture properties, and the fracture criteria itself incorporates an undetermined parameter, i.e., initial flaw size, it is hoped that the modeling can serve to determine the nature of the parameters that require measurement and to help establish the sensitivity of the response to these parameters, as well as to guide experimental efforts to attempt validation of the failure processes hypothesized. The complexity of these processes seems to demand an iterative approach between the analyst and experimentalist. Derived from text

The paper describes the potential of micromechanical studies using the instrumented Vickers indentation test in force and displacement. For ceramics reinforced by long fibers, it is possible to determine the hardness and the elastic modulus of the components as well as the mechanical characteristics of the fiber-matrix interface. Oxide and covalent (silicon carbide) matrix composites reinforced by SiC-Nicalon fibers are considered as examples. Author

Ceramics reinforced with continuous fibers exhibit delayed failure under pulsating load. A micromechanical model describing the fatigue effects is proposed. It is based on the decreasing of the shear stress at the fiber-matrix interfaces, resulting from interfacial wear due to the see-saw sliding. The main features of this model are the following: during first loading cycle, the material exhibits multiple matrix cracking and some fiber breaks. During subsequent cycles, the interfacial shear stress decreases, leading to increasing the failure probability of the bridging fibers. For a critical fraction of broken bridging fibers, instability occurs and the specimen fails, thus, defining the lifetime. For lower peak stresses, but higher still than the proportionality limit, the material also evolves but no failure occurs (up to one million cycles), indicating that the interfacial shear stress decreases to a non-zero lower bound. Fatigue induced changes of interfacial shear stress are also observed from fiber pull-out length analyses. Author

Rupture and creep behavior of ceramic matrix composites (CMC's) are discussed. The influence of the specimen geometry and size on the R-curve behavior for two types of SiC/C/SiC composite materials were investigated. The experimental results obtained using in-situ matrix crack lengths indicate that the shape of the resistance curve depends essentially on the predominant toughening mechanism (extensive matrix microcracking or fiber-matrix debonding) whereas the frontal process zone size is the same for both types of materials. K(sub R)-Delta(a) curves of SENB and small CT specimens rise as a consequence of the ligament which cannot contain the fully developed frontal process zone. Using large CT specimens, a minimum ligament size necessary to contain the frontal process zone and thus a K(sub R)-Delta(a) behavior free of structure size is observed. Creep results obtained using three point bending tests are also presented for these materials and for SiC-MLAS materials. Author (revised)

A survey is presented of research aimed at an understanding of the relation between microstructure, interface properties, and macromechanical behavior of a range of silicate (glass ceramic) and nitride matrix composites. For silicate ceramic matrix composites (CMC's), hot-pressing cycle (P/T) in relation to matrix chemistry and fiber type is critical in avoiding mechanical and chemical damage of fibers with consequent reduction in ultimate CMC strength. Interfacial debond and shear stresses, measured via a fiber 'push-down' indentation technique exhibit a wide variation, dependent on CMC processing time, temperature and matrix chemistry and thermal expansion. 'Graceful' failure, typified by 3 stage stress-strain curves, may be obtained for debond energies Gamma and shear stresses tau up to approximately 20 Jm(sup -2) and approximately 50 MPa, respectively. Interface-oxidation-induced property degradation occurs at intermediate temperatures (400-800 C) but is suppressed at higher temperatures by passive oxidation of SiC fiber ends which prevents further carbon interface removal by channeled reaction. Higher temperature SiC (Textron CVD) monofilament based CMC's with Si3N4 (SRBSN) matrices were fabricated using tape-cast matrix preforms. Partially sacrificial C-coatings on the monofilaments provide low Gamma and tau interfaces and result in ideal composite response with separation between matrix cracking stress and ultimate stress, followed by filament pull-out. Although interface oxidation is a limiting problem for creep and stress rupture, these properties are superior to turbine superalloys. Author (revised)

Ceramic matrix composites (CMC) are making up a new material family that presents a significant potential for thermostructure design. They show a good specific strength and stiffness up to high temperatures and these characteristics are associated to non-fragile behaviors which do correspond to the designer practical requirements. After a short description of the CMC most used by SEP designers, a thought on part design and dimensioning with these materials is presented. An approach of the currently used general methodology is presented, followed by various comments specific to the use of these materials. Finally, some examples of singular behaviors, which are currently poorly controlled by simple modeling and require advanced rupture criteria, are given. Derived from text

Ceramic matrix composites (CMC) have widely demonstrated their feasibility and performance although no series production has been achieved. Today's status is characterized by long production times, high material qualities with high reproducibility and experience in the first structural components. Some unsolved problems are the joining and attachment of CMC parts, the lack of adequate nondestructive testing methods and the insufficient oxidative stability for long term applications. This paper deals with general valid design aspects as a consequence of the CMC materials characteristics and the demand for structural components of high reliability. Author

Ceramic composite materials with continuous fibers in a SIC matrix, manufactured by CVI, have shown benefits for structural applications due to high fracture toughness and damage tolerance under operational conditions. However, the production time associated with the hitherto applied CVI technique entails development cycles of hardly acceptable long duration. Therefore, there is growing interest for the CVI technique to manufacture reliable CMC parts, focusing special attention on a more efficient production technology. In this paper a current attempt to develop and qualify a new CVI process, the so-called gradient-CVI, is described and discussed. This process offers increased productivity appropriate for industrial production and excellent material properties. Author

This paper outlines new concepts for the utilization of various ultrasonic techniques for the evaluation of different aspects of development and use of ceramic matrix composites. We introduce a novel mechanical parameter called the interfacial shear stiffness coefficient which can be measured using ultrasonic shear wave reflectivity technique to characterize and quantify the fiber-matrix interface. This newly proposed parameter is promising as a common basis of composite evaluation among the composites developing, composites mechanics modeling and composites testing groups. The paper will also discuss other ultrasonic NDE techniques such as ultrasonic microscopy which can provide comprehensive evaluation of the composite system during all phases of development and use. The papers presented reflect significant progress that has been made in understanding and characterizing the response of energetic materials to external stimuli such as shock, fire, and bullet impact. Small scale testing results, statistical data, and approaches to numerical modeling are reported. The need for deeper investigation of the mechanisms involved, for corroboration of the statistical results, and for better fidelity criteria of small scale testing becomes apparent. The NATO Insensitive Munitions Information Center (NIMIC), recently established in Brussels, is charged with providing more exchange of information and international cooperation. The Air Force Insensitive Munitions/Explosives Hazard Reduction Program is discussed. Key initiatives are in the barriers and packaging area are covered. Barriers and packaging which can be designed to prevent the propagation of one munitions item to the next will reduce the Maximum Credible Event (MCE). Barriers can be placed inside or outside munitions containers or between bombs on parked aircraft. Simple changes to the way munitions are packaged, such as orienting missiles within a container so that warheads do not align, may also reduce the MCE. Effective barriers and packaging can limit the MCE to one munitions item in a magazine full of munitions or one bomb in a mission ready aircraft. This will also result in significant reductions in quantity-distances required and allow more munitions to be stored in closer proximity to airbases, flightlines, and hardened aircraft shelters, where they are needed. Since the Pershing booster motor incident occurred in 1985, much has been learned about how to test for electrostatic discharge (ESD) characteristics and what factors influence ESD initiation sensitivity for solid propellants. Small propellant samples have shown enhanced ESD sensitivity when placed under pressure. Since changes in bulk solid propellant ESD traits under the influence of elevated pressures were not found in our literature surveys, equipment was fabricated so that pressure effects on ESD behavior of a hydroxy terminated polybutadiene (HTPB) propellant could be observed. In addition, a limited additive study was conducted to see if large ion salts could reduce the ESD initiation sensitivity of a sensitive HTPB propellant. Author

Composite rocket propellants traditionally developed and produced in Canada are based primarily on ammonium perchlorate (AP) dispersed in a polybutadiene (HTPB) binder. Depending on the atmospheric conditions, such propellants can produce a significant amount of secondary smoke which is undesirable for certain applications. To overcome this problem, the Defence Research Establishment, Valcartier (DREV), has initiated the development of a minimum smoke, low vulnerability propellant. The new propellant uses ammonium nitrate (AN) as the oxidizer and glycidyl azide polymer (GAP) as the energetic binder. The efforts made and the characteristics of a baseline minimum smoke formulation are described. This formulation meets minimum criteria for processing safety, chemical stability, and mechanical integrity. It falls short of the performance of an AP/HTPB propellant. Means of improving the performance are described. Author

Since the late 1970's, the Royal Ordnance Rocket Motors Division has conducted insensitive munitions trials on approximately 500 solid propellant rocket motors and data from over 400 of these have been included in a recently structured database. These trials preceded the current standards of MIL-STD-2105 and OB Proc 42657, and as a result, most of these trials were conducted on an individual bases in order to understand the basic responses to a wide range of threats. Although the trials were not undertaken as a balanced series of experiments, analysis of the data does permit some useful observation and comparisons to be made. In particular, the results of the 0.5 inch bullet impact trials and fuel fire (Fast Cook-off) tests were considered to be particularly relevant to the current UK, NATO, and USA requirements and these are discussed in detail. The general conclusions from these trials emphasize the importance of both the propellant type and body structure in the response to either mechanical or thermal attack. The database has enabled the capability of designing solid propellant rocket motors to meet bullet impact and fuel fire requirements. Author

The purpose of this paper is to describe the different families of fuel-rich solid propellants studied and developed at SNPE and ONERA for ducted rocket applications. These propellants are adjusted for choked gas generator or for unchoked gas generator configurations. They are ordered in three classes depending on their optical signature characteristics and their energetic performance: (1) smokeless propellants without metal; (2) reduced smoke compositions with a low rate of metals for a 'rustique' ducted rocket; and (3) high energy propellants with a high rate of particles--magnesium, carbon, and boron. Major properties of various fuel-rich solid propellants of each family are described. Author

This paper describes a study performed under contract to Air Force Wright Laboratory, Wright-Patterson Air Force Base, Dayton, OH in association with the Naval Air Propulsion Laboratory, Trenton, NJ. The study projected fuel temperature capability requirements for future tactical fighter applications and the payoffs that would be realized by achieving these capabilities. The study was approached on the basis of the maximum benefit that might be realized through the use of high temperature fuels, i.e. elimination of the recirculation system. Heat loads were projected for different missions spanning IHPTET technology phases 1, 2, and 3 at different flight conditions. Fuel temperatures across fuel system components were calculated at these heat loads. Shortfalls of the current 163 C fuel capability were shown, and minimun fuel temperature requirements were defined. The study concluded that elimination of the recirculation system is not feasible but shows how high temperature fuel capability can minimize the weight penalty associated with fuel recirculation. In this way, potential payoffs for high temperature fuel development were shown in the form of reduced weight penalties that would normally be encountered as larger and larger recirculation systems are required to accommodate the increasing heat loads projected for advanced aircraft. The thermal stability of aviation fuels is evaluated according to the ASTM D 2341 method. This characteristic is linked to the presence of generators of instability, mainly diolephins and N and S derivates. The objectives of the present work are as follows: to obtain, in the laboratory, kerosene which is thermally stable; the isolation and identification of generators of instability; and the regeneration of thermally unstable kerosenes. Increases in aircraft performance are leading to increases in the thermal stress on the primary aircraft coolant--the fuel. Fuel thermal stability limitations may offset future aircraft performance gains. The Air Force's Wright Laboratory is sponsoring several research programs to address this problem. The development of an additive package for JP-8 to improve its thermal stability is the primary focus of this paper. This program involves extensive testing of fuels and additives in a variety of test devices, culminating in tests in a fuel system simulator and engine tests. These tests involve Air Force personnel, on-site contractors (University of Dayton Research Institute, Systems Research Laboratories), Pratt and Whitney Aircraft Co., additive manufacturers, and Sandia National Laboratory. The test devices include several flowing and static tests, where the behavior of a fuel is investigated in a wide variety of environments. The study of several baseline fuels in these devices has led to some new insights into the mechanisms of fuel thermal (in)stability. It is becoming clear that a fuel's tendency to oxidize (to form peroxides, for example) is often inversely proportional to its tendency to form insoluble deposits. Author (revised)

Two global-chemistry models for oxidative deposition of jet fuels are evaluated by integrating them into a Computational Fluid Dynamics with Chemistry (CFDC) code. A previously developed two-step global-chemistry model was found to be insufficient to describe the thermal-oxidation and -deposition rates associated with a Jet-A fuel. A new global-chemistry model has been developed systematically based on observations from flowing and static experiments. The global-autoxidation reaction is modified such that the reaction rate becomes zeroth-order with respect to the dissolved oxygen concentration. The generation of deposit-forming precursor is coupled with the autoxidation reaction by introducing a radical species ROO. A formulation for the sticking probability has also been developed. Deposition profiles are well represented by this new model under a variety of temperature and flow conditions. The model correctly predicts the changes in magnitude and spatial location of the deposition peak due to changes in flow. The CFDC model, which is designed for flowing systems, has been extended to static experiments. The model incorporates a non-depleting species F(sub s) representing all non-oxygen compounds responsible for deposition. Static experiments were found to provide a useful and inexpensive method for estimating the concentration of F(sub s) in the fuel. Author

The creation of hypersonic vehicles and the use of jet engines with higher temperature cycles has resulted in a significant increase in the thermal stresses of the engine elements. In order to use the fuel as the coolant for these elements, it is necessary to increase the heat capacity of hydrocarbon fuels. This problem can be solved by taking advantage of such high temperature chemical processes as catalytic dehydrogenation and thermal cracking or pyrolysis of hydrocarbon fuels, including the addition of the initiators and catalysts. The chemical heat capacity of hydrocarbon fuels can be used for the direct cooling of such elements as combustion chambers, nozzles, and front wing edges; indirect cooling of these elements can be accomplished by using a heat-transport medium in the fuel/air or fuel/gas heat exchangers. The gaseous products of the decomposed fuels can be used as a working medium for the drive of the equipment of a fuel/feeding system. Author (revised)

The air defense threat to air strike forces continues to increase, both in quality and quantity. Third World countries now possess Integrated Air Defense (AID) capabilities equaling that of major powers. Radio Frequency (RF) only Anti-Radiation Homing (ARH) weapons are being effectively neutralized by countermeasure improvements in these land based and satellite IAD systems. The cost of piecemeal modification of existing weapon systems or the continuous fielding of threat specific weapon systems is becoming prohibitive. A low funded in-house project was started in 1988 that confronts this defense threat situation with a multi-mode multi-mission weapon system which is affordable to employ in large quantities. The system has capabilities as both a defense suppression weapon and a surgical strike weapon. Employment can be facilitated from a reduced threat environment to air strike forces. Other objectives for this innovative weapon system are the capabilities for high target damage, countermeasure resistance, real time aim point selection, and real time Battle Damage Assessment (BDA). Technical feasibility of the various system and subsystem elements were verified by theoretical analysis. Many were also verified by physical demonstration in prototype hardware. Author (revised)

A typical conceptual design process is described as applicable to an advanced Stand Off Weapon (SOW). Different design requirement sets, which include system performance parameters, are established to satisfy different mission requirements. In order to cope with these sets and to reach the flexibility needed, some specific design criteria are suggested. The trade between modularity and commonality makes the difference among different SOW's and affects them in affordability and effectiveness. The Skyshark weapon system is given as example of an SOW system concept. The description allows the understanding of links between design requirements, design criteria, and technical characteristics. Extensive modularity is adopted for all components that enhance flexibility (Armament, Avionics, Propulsion), while a favorable configuration layout choice allows maximizing commonality. This paper presents an industrial point of view and is related to almost 10 years of Alenia activities on Stand Off Weapons. Author (revised)

Paint stripping and repainting of aircraft surfaces are required periodically during the operating lifetime of an aircraft. Historically, paint removal has been achieved with chemical strippers. These materials often contain toxic components and create hazardous working conditions. It is necessary to ensure that alternate paint removal techniques are available that can be performed in a cost effective, environmentally safe manner without causing damage to aircraft surfaces. For individual titles, see N94-10614 through N94-10629.

PAINT REMOVAL ACTIVITIES IN THE US NAVY

JOSEPH KOZOL *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal 5 p (SEE N94-10613 01-31) Mar. 1993

(AGARD-R-791) Copyright Avail: CASI HC A01/MF A02

Use of methylene chloride and phenol based chemical strippers for aircraft paint removal generates large quantities of hazardous waste and creates health and safety problems for operating personnel. This paper presents an overview of the U.S. Navy's activities in the investigation and implementation of alternate paint stripping methods which will minimize or eliminate hazardous waste and provide a safe operating environment. Alternate paint removal methods under investigation by the Navy at the present time include use of non-hazardous chemical paint removers, xenon flashlamp/CO2 pellets, lasers and plastic media. Plastic media blasting represents a mature technology in current usage for aircraft paint stripping and is being investigated for determination of its effects on Navy composite aircraft configurations. Paint removal activities currently under way in Canada include: research and development of laser paint stripping; development and commercialization of a new blasting medium based on wheat starch; commercialization of a new blasting medium and process using crystalline ice blasting for paint removal and surface cleaning; and the development of automated and robotic systems for paint stripping applications. A specification for plastic media blasting (PMB) of aircraft and aircraft components is currently being drafted by NDHQ for use by the Canadian Armed Forces (CAF) and contractors involved in coating removal for the CAF. Defense Research Establishment Pacific (DREP) is studying the effects of various blast media on coating removal rates, and minimizing the possibility of damage to substrates other than aluminum such as graphite epoxy composite and Kevlar. The effects of plastic media blasting on liquid penetrant detection of fatigue cracks is also under investigation. Author (revised)

In 1987, Fokker Aircraft Services started F.16 air-intake paint removal by means of Plastic Media Blasting (PMB). Especially for this process, a robot has been developed. In a later stage, complete exterior PMB-paint removal has been tested and successfully adopted. The paint removal is carried out in the scope of a thorough corrosion control program. The requirement that all the paint must be removed in order to allow this control program to be carried out properly, leads to severe masking complications. The process parameters are relatively conservative, because of the requirement that absolutely no anodic layer damage is permitted. Following PMB paint removal, corrosion is removed using aluminum oxide blasting. Finally, a highly flexible polyurethane paint system is applied, based upon TT-P-2760 Koroflex primer. To summarize the process, it can be stated that the plastic media blasting itself is straightforward. Proper masking is difficult to perform though, compounded by special customer requirements such as open panel edges. Author (revised)

In order to meet constant financial and reliability concerns, European manufacturers have introduced more and more composite materials on their aircraft. In addition to fairings for which the use of composites has become absolutely necessary, composites are used on each new program for structures which are more and more highly loaded and sophisticated. Similarly to metallic structures, an external paint scheme is applied to these composite structures to protect them from ultraviolet rays, provide general corrosion resistance and allow the airlines to customize their aircraft. Conventional stripping methods using chemical strippers cannot be used as many impregnation resins do not resist chemical strippers. Aerospatiale has endeavored to find new efficient methods that are easy to implement, cause no damage and are applicable both to metallic and composite structures. Dry stripping via plastic media blasting has formed the subject of many tests. These tests proved that such stripping was compatible with the objectives but required automation of the process for large airframe stripping. Author

German Air Force (GAF) has been researching a method of paint removal for a couple of years to replace the chemical method still in use. This is to improve corrosion prevention, environmental protection and health care. With the support of German aerospace company MBB and the University of the Armed Forces in Munich GAF selected Plastic Media Blasting (PMB) as the most suitable method. Having a stripping facility for the entire aircraft at MBB Manching already in existence, GAF decided that the next step forward to gain more experiences is to establish a smaller 'stripping cabin' at an air force base. This cabin is suitable for stripping removable parts and components of aircraft and equipment with the max. size of a half dismantled TORNADO wing. With these gained experiences GAF will be in position to formulate the specific requirements for an entire on-base aircraft stripping plant which will be suitable for F-4's, TORNADO's and EFA's, too.

Hill Air Force Base in Utah developed plastic media blasting (PMB) paint removal process for removing paint from Air Force aircraft. The development of the process involved extensive testing of various abrasives and subsequent parameters to end up with an approved production process. Hill AFB has been using PMB in a production mode since 1985, and completely discontinued chemical stripping of airframes in 1989. We have recently installed and began operating a fully automated PMB facility that utilizes two nine-axis robots to strip an aircraft. This system has enabled us to further reduce the manhours required to strip an aircraft, and also allowed us to remove the employee from the blasting atmosphere into a control room. We have, and will continue to realize, significant environmental and economic savings by using PMB. Hill is also actively involved with the development of future paint stripping technologies. The aircraft maintenance industry is beset by new Environmental Protection Agency (EPA) guidelines on air emissions, Occupational Safety and Health Administration (OSHA) standards, dwindling labor markets, Federal Aviation Administration (FAA) safety guidelines, and increased operating costs. In light of these factors, the USAF's Wright Laboratory Manufacturing Technology Directorate and the Aircraft Division of the Oklahoma City Air Logistics Center initiated a MANTECH/REPTECH effort to automate an alternate paint removal method and eliminate the current manual methylene chloride chemical stripping methods. This paper presents some of the background and history of the LARPS program, describes the LARPS system, documents the projected operational flow, quantifies some of the projected system benefits and describes the High Pressure Water Stripping Process. Certification of an alternative paint removal method to replace the current chemical process is being performed in two phases: Process Optimization and Process Validation. This paper also presents the results of the Process Optimization for metal substrates. Data on the coating removal rate, residual stresses, surface roughness, preliminary process envelopes, and technical plans for process Validation Testing will be discussed. Author (revised)

To date, the DoD has played a major role in funding a number of paint stripping programs. Some technologies have proven less effective than contemplated. Others are still in the validation phase. Paint stripping is one of the hottest issues being addressed by the finishing industry since the Environmental Protection Agency (EPA) has mandated that chemical stripping using methylene chloride/phenolic type strippers be stopped. The DoD and commercial aircraft companies are hard-pressed to find an alternative. Automated laser paint stripping has been identified as a technique for removing coatings from aircraft surfaces. International Technical Associates (InTA) was awarded a Navy contract for an automated laser paint stripping system (ALPS) that will remove paint from metallic and composite substrates. For the program, which will validate laser paint stripping, InTA will design, build, test, and install a system for fighter-sized aircraft at both the Norfolk and North Island (San Diego) Aviation Depots.

Environmental, safety and health issues, forced operators to search for an alternative paint removal process. High pressure water jetting and new integrated paint and stripper systems are Lufthansa's answer to this challenge. AQUASTRIP complies with the specification requirements. In order to receive approval from airframe manufacturers and authorities the process has undergone an extensive research program since 1988. An operation window was established, to enable maximum of safety during operation on metal and composite surfaces. Even though AQUASTRIP is a hybrid process and requires technological investment, it is well on the way to prove its innovative, ecological and economical character in first large scale applications under realistic conditions. Its potential has already been reflected by patents and trademarks, which were registered in conjunction with the development of AQUASTRIP and the vital interest for cooperative work on the process development and other potential utilization.

Research into the possibility of using ice particles as a blast medium was first initiated at Defence Research Establishment Pacific (DREP) in an effort to develop a more environmentally acceptable paint removal method. A paint removal process was also required that could be used in areas where normal grit blasting could not be used due to the possibility of the residual blasting grit contaminating machinery and other equipment. As a result of this research a commercial ice blasting system was developed by RETECH. This system is now being used to remove paint from substrates that cannot be easily blasted by conventional techniques and also to clean soiled or contaminated surfaces. The problems involved in the development of an ice blast system, and its components and their functions are described. Due to the complexity of paint removal using ice blasting, parameters such as air pressure, ice particle size and ice particle flow rate were studied and adjusted to suit the nature of the particular coating and substrate of interest. The mechanism of paint removal by ice particles has also been investigated. A theoretical model has been developed to explain the different paint removal mechanisms such as erosion by abrasion and erosion by fracture as they relate to ice blasting. Finally, the use of ice blasting to removal paint from a variety of substrates is presented as well as examples of surface cleaning and surface decontamination. Author

A review of the Wheat Starch Blasting technology is presented. Laboratory evaluations covering Almen Arc testing on bare 2024-T3 aluminum and magnesium, as well as crack detection on 7075-T6 bare aluminum, are discussed. Comparisons with Type V plastic media show lower residual stresses are achieved on aluminum and magnesium with wheat starch media. Dry blasting effects on the detection of cracks confirms better crack visibility with wheat starch media versus Type V or Type II plastic media. Testing of wheat starch media in several composite test programs, including fiberglass, Kevlar, and graphite-epoxy composites, showed no fiber damage. Process developments and production experience at the first U.S. aircraft stripping facility are also reviewed. Corporate and regional aircraft are being stripped in this three nozzle dry blast hangar. Author

In 1990 the International Air Transport Association (IATA) established a task force to stimulate the development of alternatives for chemical stripping of commercial aircraft. The IATA TaskForce Paintstripping objectives are: to identify the most promising, current alternatives for short term implementation; to prepare a document containing requirements for the development of alternatives; to stimulate the information exchange. After the September 1992 meeting the TaskForce will report back to IATA.

The most tangible result of the TaskForce is the IATA Guidelines containing requirements for the qualification of stripping processes. Author (revised)

In order to meet the requirements of more environmentally acceptable paint stripping processes many different removal methods are under evaluation. These new processes can be divided into mechanical and chemical methods. ICI has developed a paint scheme with intermediate coat and fluid resistant polyurethane topcoat which can be stripped chemically in a short period of time with methylene chloride free and phenol free paint strippers. We examine signal fading statistics over a year period corresponding to two over-water, line-of-site, propagation links in the mid-Atlantic coast of the US. These links are comprised of a transmitter on a tower at Parramore Island, VA operating at 4.7 GHz sending simultaneous cw signals to two receiver systems located on a lighthouse and a lookout tower on Assateague Beach, VA at distances of 44 and 39 km, respectively. The receiving sites are separated by approximately 5 km. Cumulative fade distributions corresponding to yearly, monthly, and diurnal time scales were derived. Fade duration statistics correspond to sustained attenuation events were also derived. These events, which were arbitrarily defined as having fades relative to free space powers in excess of 20 dB for durations of two hours or more, are believed to be generally due to subrefraction. Analysis of synoptic weather conditions and nearby rawindsonde data during two sustained deep fading periods showed atmospheric conditions consistent with extreme subrefraction, where the refractivity-height profile had a positive lapse rate. The efficacy of employing the links as indicators of real time conditions of atmospheric propagation was also demonstrated by a telephone call-up procedure which enabled displays of time series of the fading at remote locations to be generated. In the context of work undertaken by the Propagation subgroup AC 243/RSG8/com. III, two important series of measurements were taken in the neighborhood of the French coast: in the Atlantic (Lorient region) in the Fall of 1989, and in the Mediterranean (Toulon region) during the summer of 1990. These were measurements of over-the-horizon links above the sea, at a sweeping angle, with wavelengths in centimeters and millimeters (from 3 to 94 GHz). In order to precisely characterize the limit layer of the oceanic surface, meteorological measurements were undertaken using automatic stations on buoys placed near the line of sight and radiosondes suspended from balloons. The data set gathered enables the completion and validation of a program for global calculation of propagation in a marine environment. This program is constructed from a propagation model, based on the parabolic equation method and from an environment model developed based on a 'bulk' type procedure. Statistical analysis of the experimental data demonstrates the good quality of the combination of models used. The advantage of a multifrequency approach is also clearly shown. However, the temporal comparison between predicted and measured propagation losses proves to be more complex. An appreciable improvement can be made by taking into account the level of measurements taken and environmental models, complex atmospheric situations, and spatial discrepancies. Transl. by L.B.

The aim in this study is to consider the possibility of identifying the evaporation duct parameters from a fluctuation analysis of a near the horizon satellite-ship path. The latter is split in two different parts and reciprocity is applied. Thus, we get two different field distributions on a connecting interface which has to be suitable for a good calculation of the coupling between both of them. Then, the model is used with the intention of evaluating the fluctuations of the received signal due to the movement of the satellite and their sensitivity to the parameters of the propagation medium: sea roughness, height, and strength of the evaporation duct; and presence of horizontal gradients in the refractive index distribution. Obviously, sensitivity to these parameters is examined for several values of the frequency. Author

A technique is presented for estimating radio wave ducting conditions from shipboard curing cloud-free periods using a lidar system to measure the power from a pulsed laser beam that is backscattered to a receiver from suspended particulates (aerosols) at different ranges. On individual days, the relative humidity measured with altitude using radiosondes launched simultaneously with vertical lidar shots, were highly correlated with the range-compensated power received by the lidar from the same altitude. However, the relationship between the power returns and the relative humidities changed from day to day, indicating an air mass characteristic dependence on the aerosols' optical parameters. Using a combined data set of 13 days, a linear relationship (correlation = 0.73) was determined between the relative humidity at a given altitude and the range-compensated power received by the lidar from the same altitude. While the magnitudes differed in most cases, the gradients in modified radio refractivity calculated using standard vertical lapse rates of temperature and pressure with the experimentally determined relationship were in close agreement with those calculated using the radiosonde measured parameters. Examples of radio signal coverage plots based on the lidar returns are presented and

compared with those calculated from the radiosonde data for both elevated and ground-based ducting conditions. Author

Three-dimensional forecasts of sensor performance require accurate predictions of refractivity features. Numerical weather models like the UK mesoscale model have become sufficiently powerful to provide good refractivity maps. These in turn provide environmental input for parabolic equation models to forecast microwave propagation. The UK mesoscale model and its application to forecasting sensor performance are briefly described. Author

Capabilities of estimating ducting conditions for certain ocean regions (and weather regimes) from meteorological satellite data are under development at the Pacific Missile Test Center, in support of the Navy's Electromagnetic Propagation Assessment and Tactical Environmental Support System (TESS) program offices. Visual imagery patterns are used to infer the occurrence, height, and intensity of ducts, while processed infrared (IR) and visual imagery are used to infer the spatial distribution of duct heights. Special cloud signature techniques were developed on a personal computer to help correct for contamination of cloud-top temperatures due to sea and cloud anomaly features which impact the IR-duct technique. Synoptic, mesoscale, and geographical influences on the propagation environment are considered as part of the effort to develop a predictive capability. Author

Recent measurements by the Mobile Imaging Spectroscopy Laboratory (MISL) have shed new light on the real degradation produced by atmospheric propagation on far-infrared imaging systems. By the hot and cold bars and the unique measurement technique of closeup and distant simultaneously collected matched imagery of a large area blackbody target board, the atmospheric modulation transfer function (AMTF) was shown to be definitely nonzero for both atmospheric horizontal path turbulence and aerosol clouds. In addition, observations of the target board without the bar pattern and uniform backgrounds were used to compare the MISL measured contrast transmission with LOWTRAN calculations. D.R.D.

A channel sounder called RUSK 400 is described. It is capable of recording complex impulse responses (IRs) in mobile environment. Thanks to digital signal processing, RUSK 400 measures IRs with large dynamic range. RUSK 400 was calibrated to allow for quantitative analysis. Doppler analysis of the measured results can be performed because the data are stored rapidly, and therefore, the sampling theorem can be fulfilled. For determination of delays, the resolution is restricted to about 5 microns because of the small bandwidth of only 400 kHz. The resolution is good enough to perform propagation measurements with the goal of improving of propagation models which use topographical terrain data bases. The determination of angles of arrival is restricted; reasons are given and discussed. The shortcomings of poor resolution and left-right ambiguity can be overcome if it is possible to measure complex IRs at the same location by driving in different directions. RUSK 400 will be used for quantitative determination of magnitudes of waves scattered by terrain slopes. The results will be used to improve automatic field strength prediction methods and estimation of the delay spread caused by mountains. Author

Basic principles of radar polarimetry are introduced. The target characteristic polarization state theory is developed first for the coherent case using the three step, the basic transformation, and the power (Mueller) matrix optimization procedures. Kennaugh's and Huynen's theories of radar target polarimetry are verified for the monostatic reciprocal case. It is shown that there exist in total five unique pairs of characteristic polarization states for the symmetric scattering matrix of which the two pairs, the cross polarization null and copolarization max pairs, are identical; whereas, the cross pol max and the cross pol saddle point are distinct. These three pairs of orthogonal characteristic states are also mutually orthogonal on the polarization sphere. The fifth pair, the co-pol null pair lies in the plane spanned by the co-pol max/-cross pol null and the cross pol max pairs which determines the target characteristic circle on the polarization sphere reestablishing Huynen's polarization fork concept. The theory is verified by an example for which next to the polarization fork also the copolarized and cross polarized power density plots are presented. Author

Basic principles of radar polarimetry are applied to radio communications under the conditions that the polarization state of the incoming wave changes according to effects caused by the propagation environment. Since the polarization state of an incoming wave cannot be controlled, the only possible way to control the receiving power is the polarization state of the receiving antenna. Based on basic principles of radar polarimetry, the matching and mismatching conditions are derived using the Poincare sphere. An interesting relation was found between the maximal and minimal polarization states with respect to that of the incoming wave, i.e., these points constitute a great circle on the Poincare sphere and that they form a right angle triangle on the great circle. Therefore, if the polarization of the incoming wave is given, these maximal and minimal polarization points can be determined graphically on the Poincare sphere instantaneously. This concept of adaptive communications polarimetry may be useful not only to cellular radio communication systems, but to fixed station link radio communication systems suffering from atmospheric fluctuations as well. Fiber-optics is progressively changing from the research stage to the field of application. However, new possibilities are emerging, which will bring a new revolution in the field of telecommunications, such as coherent transmission, new transmission material transparent to mid-infrared radiation, active fibers, and soliton propagation. Fiber-optics is gaining increasing importance in tactical missile and aircraft guidance and control. This has been driven by the commercial development of fiber optic cable and related components. The requirements for military guidance and control applications are highly demanding for the characteristics of fibers and necessary related components (transmitters, receivers, connectors, etc.). For individual titles, see N92-28085 through N92-28093.

Coherent lightwave techniques, when compared to direct detection techniques, offer nearly quantum noise limited sensitivity as well as fine tunability similar to that obtained at radio frequencies. These two aspects provide communication systems planners and engineers a means to better exploit the huge bandwidth of single mode optical fibers. Field trials have been performed showing that such techniques are suitable for transmitting multigigabit per second signals to distances exceeding well over a hundred kilometers. On the other hand, coherent multichannel, frequency division multiple access, local area networks have been proposed and experimented with worldwide. This paper will discuss the theoretical advantages and limitations of the various modulation and detection formats together with the state of the art. Moreover some aspects, related to the introduction of coherent systems in local and metropolitan area networks, will be treated. Finally, some experimental data will be provided and future evolution will be discussed. Author

Radical changes are taking place in the computer architecture landscape. The big mainframes are being replaced by networks of microcomputers distributed over a wide geographical area. Increases in the speed and memory of computers has created a need for a communication medium capable of transmitting data at a rate exceeding gigabits per second. The low loss, low dispersion optical fiber is the breakthrough that makes high data rate transmission a reality. H.A.

During a penetration mission, modern tactical aircraft have to fly over regions with heavy electromagnetic environments. To realize such a mission, a minimum knowledge of terrain elevation is needed. Terrain elevation knowledge can be obtained from real time sensors such as radar. The development of terrain following function becoming more and more complicated, it necessitates the use of simulations to analyze the performance of sophisticated data processing and flight control. The aim of this paper is to demonstrate the contribution of interactive real time simulations during the phase of development to optimize radar resources management, in different types of terrain and many configurations of electronic warfare. It is then shown how the operational people can take part to the definition of the radar to obtain the most appropriate comportment. It is finally described how to characterize the radar performances in the complete weapon system and observe the manifestation of error simulation on the security of the system. Author

FUNDAMENTALS AND SPECIAL PROBLEMS OF SYNTHETIC APERTURE RADAR (SAR) [LES ASPECTS FONDAMENTAUX ET LES PROBLEMES SPECIFIQUES AUX RADARS A OUVERTURE SYNTHETIQUE (SAR)]
Aug. 1992 196 p Lecture series held in Bad Neuenahr, Germany, 5-6 Oct. 1992, in Gebze-Kocaeli, Turkey, 8-9 Oct. 1992, and in Ottawa, Ontario, 26-27 Oct. 1992
(AGARD-LS-182; ISBN-92-835-0683-9; AD-A255697) Copyright Avail: CASI HC A09/MF A03

The influence of the antenna parameters on specification and capabilities of SAR and the advantages, necessities, and limits will be considered. Digital SAR processing is indispensable for SAR. Theories and special algorithms will be given along with basic processor configurations and different processing techniques on a hardware and software basis. The simulation of SAR-systems as well as SAR-products will also be a topic of the Lecture Series. A presentation of the present state of the art, giving examples of presently planned and realized airborne and spaceborne SAR with its foreseen applications will conclude the Lecture Series. This Lecture Series was sponsored by the Avionics Panel of AGARD and the Consultant and Exchange Program of AGARD. For individual titles, see N93-13050 through N93-13060.

A synthetic aperture radar (SAR) is basically a coherent scatterometer that employs a coherent real aperture radar with highly sophisticated data evaluation and image processing capabilities. Therefore, the coherence of the system is very important; furthermore, the keypoints for SAR are data storage, evaluation, and processing. These facts entail peculiarities of SAR and special ambiguities which are different from those arising with real aperture radar (RAR). The objective of this paper is to point out the special peculiarities and ambiguities of SAR in comparison to the corresponding properties of RAR. Main topics in this connection are as follows: basic peculiarities like range dependency of signal to noise ratio; azimuth resolution; influence of platform velocity; range and azimuth ambiguities; pulse repetition frequency limitations; velocity effects; and phase error influence, on SAR-image, that can cause motion compensation problems. All these effects will be explained together with different contrast-equations between the target and clutter signals of SAR and RAR. Author

MOTION ERRORS AND COMPENSATION POSSIBILITIES

DAVID HOUNAM *In* AGARD, Fundamentals and Special Problems of Synthetic Aperture Radar (SAR) 12 p (SEE N93-13049 03-32) Aug. 1992

(AGARD-LS-182) Copyright Avail: CASI HC A03/MF A03

The synthetic aperture radar (SAR) technique relies on knowledge of the relative motion between the sensor and the target. If the flight path of the sensor is not accurately known or the SAR processor is limited in its ability to take the flight data into account, the SAR image will be degraded. Motion errors are particularly critical for SAR sensors on small, low-flying aircraft, due to turbulence, and where high spatial resolution is required. The lecture discusses the effects of motion errors on image quality and the requirements on the sensor and processor to compensate for motion errors. The DLR airborne sensor, E-SAR, and associated image processor will be used as examples. Techniques using a priori knowledge of the flight path from independent sensors, e.g., inertial navigation systems (INS), and by extracting the flight data from the SAR data, e.g., autofocus and reflectivity displacement method (RDM), are treated. THE REAL APERTURE ANTENNA OF SAR, A KEY ELEMENT FOR PERFORMANCE

HERWIG OETTL *In* AGARD, Fundamentals and Special Problems of Synthetic Aperture Radar (SAR) 8 p (SEE N93-13049 03-32) Aug. 1992

(AGARD-LS-182) Copyright Avail: CASI HC A02/MF A03

For a SAR system flying on an airborne or spaceborne platform, the real antenna must be designed in such a way so as to avoid ambiguities and achieve the envisaged resolution. Although a SAR is, with respect to geometric azimuth resolution, independent of its distance from a target, the ground range resolution depends on the incidence angle and, of course, on the bandwidth dependent slant range resolution. The antenna size and its half power beam width (HPBW) in azimuth and elevation define its azimuth resolution and, for a given off-nadir angle and chosen altitude, the swath width. The minimum antenna size, measured in wavelengths, depends on the altitude, velocity of the platform, and chosen off-nadir angle. In real antenna design, the aperture size will be somewhat larger in order to allow for amplitude taper (at least in elevation), for electronic beam steering and possibly for beam shaping. This paper explains the interdependence of antenna parameters with SAR system performance. Author

Imaging radar polarimeters are usually implemented using a Synthetic Aperture Radar (SAR) approach to give a high resolution image in two dimensions: range and azimuth. For each pixel in the image a polarimetric SAR gives sufficient information to characterize the polarimetric scattering properties of the imaged area (or target) as seen by the radar. Using a polarimetric SAR system as opposed to a single-polarization SAR system provides significantly more information about the target scattering mechanisms and allows better discrimination between different types of surfaces. In these notes a brief overview of SAR polarimetry is offered. The notes are intended as a text to accompany a lecture on SAR polarimetry as part of an AGARD-NATO course. Covered in the notes are the following: the polarization properties of electromagnetic waves; the concepts of radar scattering and measuring radar backscatter with a SAR; polarization synthesis; scattering matrix, Stokes matrix, and covariance matrix representations of polarimetric SAR data; polarization signature plots; design and calibration of polarimetric SAR systems; polarization filtering for target detection; fitting a simple model to polarimetric SAR measurements of naturally occurring features; and supervised classification of polarimetric SAR data. RADIOMETRIC CALIBRATION OF SAR SYSTEMS

HERWIG OETTL *In* AGARD, Fundamentals and Special Problems of Synthetic Aperture Radar (SAR) 9 p (SEE N93-13049 03-32) Aug. 1992

Most SAR image interpretation performed in recent years was based on data which were often insufficiently calibrated. Ground truth data were used for comparison and interpretation. The importance of calibration was recognized by the need for reproducible data, by the introduction of multifrequency and multipolarization systems (interchannel calibration), and the long term scope of remote sensing. Hydrologists, especially, requested an absolute calibration with tolerances of less than 1 dB. Internal calibration schemes, as well as the use of external passive and active calibrators, were introduced to achieve this goal over the wide dynamic range. The in-flight measurement of the antenna pattern by means of ground based receivers became increasingly important due to pattern changes caused by electronic beam steering and the necessity of beam alignment in case of multifrequency and/or polarimetric operation modes. The use of radiometric corrections to compensate for near range/far range differences caused by the antenna pattern and geometry of illumination will be explained in the lecture. The impact of geocoding on radiometric levels will also be mentioned, including the phenomenon of over-/underexposing hilly regions, caused by incidence angle changes. Author

The use of software tools as an investigative method is particularly important in the case of synthetic aperture radar sensors, as the geometry cannot be reproduced in the laboratory. Also, the complete SAR system, from the target via the propagation path, sensor and image processor to the final image, represents a highly complex data chain, which cannot be treated in part. The lecture discusses different approaches from parametric analysis tools to full-blown simulators capable of analyzing all elements of the SAR system. The latter will be illustrated with the aid of the SARSIM simulator, which was used for confirming parameters of the ERS-1 Active Microwave Instrument (AMI). Particular emphasis will be placed on the simulation of target scattering mechanisms, the understanding of which is essential if the potential of SAR systems is to be fully exploited, and on the modelling of sensor characteristics. ISAR is a technique, based on time and Doppler frequency analysis, which is used for imaging of targets having rotational motions with regard to the radar. In the sixties, observation of the Moon and planets by a radar located on the Earth was one of the first applications. Closely derived from these first trials, imaging of objects in terrestrian orbit by ISAR techniques is performed with interesting results. However, the most current domains of application of ISAR are now measurements of target signatures and target recognition. Author

This Lecture provides a concise summary of the state of the art in SAR systems, both spaceborne and airborne. The first civilian SAR mission in space was the United States' SEASAT (L-band), operating Jul. - Sep. 1978. It was followed by two Shuttle missions of one week duration each, SIR-A (L-band, Nov. 1981), and SIR-B (L-band, Oct. 1984). The 1990's are witnessing a flurry of orbital SAR activity, with Almaz (USSR, S-band, Mar. 1991), ERS-1 (ESA, C-band, Jul. 1991), J-ERS-1 (Japan, L-band, Feb. 1992), SIR-C/X-SAR (USA/Germany and Italy, L-, C- and X-bands, three launches planned after 1993), ERS-2 (ESA, repeat mission), and RADARSAT (Canada, C-band, 1995) taking place in the decade. System parameters are included in Tables, and general characteristics of these radars are compared and contrasted. The lecture also provides an overview of airborne SAR systems, including those of NASA (USA), CCRS (Canada), Intera/MDA (Canada), DLR (Germany), and TUD (Denmark), among others. Author

The field of speech processing is undergoing a rapid growth in terms of both performance and applications and this is fueled by the advances being made in the areas of microelectronics, computation, and algorithm design. The use of voice for civil and military communications is discussed considering advantages and disadvantages including the effects of environmental factors such as acoustic and electrical noise and interference and propagation. The structure of the existing NATO communications network and the evolving Integrated Services Digital Network (ISDN) concept are briefly reviewed to show how they meet the present and future requirements. The paper then deals with the fundamental subject of speech coding and compression. Recent advances in techniques and algorithms for speech coding now permit high quality voice reproduction at remarkably low bit rates. The subject of speech synthesis is next treated where the principle objective is to produce natural quality synthetic speech from unrestricted text input. Speech recognition where the ultimate objective is to produce a machine which would understand conversational speech with unrestricted vocabulary, from essentially any talker, is discussed. Algorithms for speech recognition can be characterized broadly as pattern recognition approaches and acoustic phonetic approaches. To date, the greatest degree of success in speech recognition has been obtained using pattern recognition paradigms. It is for this reason that the paper is concerned primarily with this technique. MULTIVARIABLE FREQUENCY RESPONSE METHODS FOR OPTIMAL KALMAN-BUCY FILTERS WITH APPLICATIONS TO RADAR TRACKING SYSTEMS
C. C. ARCASOY *In* AGARD, Advances in Guidance and Control of Precision Guided Weapons 14 p (SEE N93-22018 08-31) Nov. 1992
(AGARD-CP-524) Copyright Avail: CASI HC A03/MF A02

The problem of multi-output, infinite-time, linear time-invariant optimal Kalman-Bucy filter both in continuous and discrete-time cases in frequency domain is addressed. A simple new algorithm is given for the analytical solution to the steady-state gain of the optimum filter based on a transfer function approach. The algorithm is based on spectral factorization of observed spectral density matrix of the filter which generates directly the return-difference matrix of the optimal filter. The method is more direct than by algebraic Riccati equation solution and can easily be implemented on digital computer. The design procedure is illustrated by examples and closed-form solution of ECV and ECA radar tracking filters are considered as an application of the method. Author

The discussed navigation update system was designed for an unmanned platform with fire and forget capability. It meets the requirement due to fully autonomous operation. The system concept will be characterized by complementary use of the radar seeker for target identification as well as for navigation function. The system works in the navigation mode during preprogrammable phases where the primary target identification function is not active or in parallel processing. The dual function radar seeker system navigates the drone during the midcourse and terminal phases of the mission. Its high resolution due to range measurement and doppler beam sharpening in context with its radar reflectivity sensing capability are the basis for topography referenced navigation computation. The detected height jumps (coming from terrain elevation and cultural objects) and radar reflectivity features will be matched together with topography referenced features. The database comprises elevation data and selected radar reflectivity features that are robust against seasonal influences. The operational benefits of the discussed system are as follows: (1) the improved navigation performance with high probability of position fixing, even over flat terrain; (2) the operation within higher altitudes; and (3) bad weather capability. The developed software modules were verified with captive flight test data running in a hardware-in-the-loop simulation. Author (revised)

Modern defense systems must have a comprehensive surveillance capability. A key component of a surveillance system is the ability to detect and to locate radio signals in the entire radio spectrum from extremely low frequencies through millimeter wavelengths. Various techniques are used to determine the angle of arrival of a radio signal and the distance to the source. This often involves complex signal processing techniques. The symposium addressed first propagation aspects with emphasis on ionospheric characteristics and effects. Two sessions were devoted to the description of radio location techniques such as single site location and another two to radio location measurements and systems. One session covered signal processing techniques in radio location applications. One session covered classified subjects and will be published in a classified addendum. For individual titles, see N93-23599 through N93-23631.

LATERAL DEVIATION OF VLF RADIO WAVES DUE TO DIFFRACTION AND SCATTERING FROM COAST-LINES, MOUNTAIN RANGES, AND POLAR ICE CAPS
JAMES R. WAIT *In* AGARD, Radiolocation Techniques 12 p (SEE N93-23598 08-32) Nov. 1992
(AGARD-CP-528) Copyright Avail: CASI HC A03/MF A03

This paper deals with a physical theory of radio wave propagation in the earth ionosphere waveguide when allowance is made for lateral non-uniformities in the lower boundary. A combined hybrid ray and mode analysis is adopted which reduces to the now conventional formulation when the lower boundary is uniform. For obvious reasons, the mathematical details will not be presented but the optical interpretation is given and the physical concepts are illustrated in a meaningful fashion. A case of particular interest is when the global propagation of the VLF signal arrives from both the direct path as well as a sometimes very strong resonant scatter from a continental mountain range 1000 km or more off the great circle path. Other examples occur when the signal actually diffracts around convex coast-lines and continental margins such as the Antarctic ice cap. In such cases, the direct path signal over the highly lossy medium is highly attenuated and may be out of contention. In the simplest theory of 'horizontal bending' of VLF wave guide modes, the conversion of modes, of one order to another, is ignored. But, by employing mode match techniques, the conversion of modes of order m to modes of order n (reflected) and to modes of order p(transmitted) can be estimated. Both a scalar and a vector version of the formulation are outlined. Actually the scalar version is really more appropriate for dealing with acoustic ducts with inhomogeneous walls when the horizontal direction of propagation is oblique to the junction planes. Strictly speaking the full blown vector problem must be dealt with in the electromagnetic case if proper allowance is to be made for the inevitable coupling between the TM (transverse magnetic) and TE (transverse magnetic) modes. PROPAGATION CHARACTERISTICS OF THE IONOSPHERIC TRANSMISSION WINDOW RELATING TO LONG WAVE RADIO LOCATION ISSUES
PAUL A. KOSSEY and EDWARD A. LEWIS (Systems Integration Engineering, Inc., Lexington, MA.) *In* AGARD, Radiolocation Techniques 17 p (SEE N93-23598 08-32) Nov. 1992
(AGARD-CP-528) Copyright Avail: CASI HC A03/MF A03

Most applications of long radio waves (ELF/VLF/LF/MF) are ground-based and exploit the fact that such signals can propagate to great distances via reflections from the lower ionosphere. It is known however that, owing to the influence of the earth's magnetic field, long wave signals can penetrate through the ionosphere as well; at times, the waves penetrate with relatively little loss, depending on ionospheric conditions and other propagation factors. This has prompted investigations of the long wave 'ionospheric

transmission window' as part of efforts to assess the feasibility of deploying long wave emitters in space for terrestrial applications and/or for exploiting, in space, signals emanating from ground-based long wave transmitters. This paper outlines results of theoretical and experimental investigations of the ionospheric transmission window over the frequency range from about 100 Hz to 500 kHz, with emphasis on directional issues associated with long wave penetration of the ionosphere. Unambiguous locations for target transmitters are based on lines of bearing (LOB's) obtained by radio direction finding (DF) methods. These target location estimates based on intercepted LOB's are subject to error if multipath exists. This multipath may result from sky wave interference or sea scatter from rough seas. Sky wave multipath becomes important for ranges greater than 300 km while ground wave multipath may be significant for ranges less than about 100 km. Although, the groundwave loss may be greater than the one-hop sky wave mode, it may be comparable to the loss associated with the two-hop mode. Therefore both groundwave and sky wave multipath may contribute to LOB errors for a given fleet exercise. For the case of sky wave multipath, newer DF systems will be able to differentiate sky wave signals from ground wave signals when the elevation angle is greater than about 18 deg. In this paper, groundwave multipath is estimated using the compensation theorem. This method provides a convenient analytical tool for relating the change in mutual impedance between a transmitting monopole and a receiving loop over a rough sea surface and a flat sea. The change in mutual impedance, in turn, is related to the change in current in each of the receiving loops used to generate LOB's. Some predicted and observed examples of fleet exercise LOB errors from wind generated swell will be given based on target transmitter frequency, wind direction, and speed of the ship carrying the DF system.

Estimates are made of the propagation errors that can be made in the measurement of the geographic coordinates of an HF emitter when utilizing HF direction finding techniques. The sources of the errors considered in this analysis are those due to the following: (1) imprecise knowledge of the ionospheric reflection height; (2) ionospheric tilts, i.e., gradients of electron density; and (3) tropospheric refractive bending. Modeling of the ionosphere is a necessity in numerous applications: the physical study of an area, telecommunications, transhorizon radars, and radio location. Radio location from a single sensor is particularly attractive but requires, in the decametric propagation range, knowledge with a sufficient precision of the ionospheric area within which the trajectories of the radii are controlled, not only by the vertical profile of the ionization, but also by the horizontal gradient. A tracing of a radius in an ionosphere is investigated by making use of a Bradley-Dudeney model in the presence of horizontal gradients whose transversal components are not null. One can see that the components draw the propagations outside of a large circle with important deviations on the ground due to the reflection occurring in region F. Taking into account these gradients is indispensable for a correct location, which makes their estimation necessary. Radio location from a single sensor necessitates therefore the placement in the same location of a means of measurement. A retrodiffusion probe easily brings anisotropies to light. It represents a simple means which is possible to put to work with very little power and is therefore attractive. The principal difficulty of this technique is in the resolution of an inverse problem which, aside from the measurements obtained, permits the discovery at all points of the observation zone of the vertical profile from which the gradients are deduced. It is a difficult problem which has not yet really received a totally satisfactory solution in spite of important efforts produced by the scientific world. The stabilization of the solution appears to be possible thanks to new techniques which allow the measurement of new parameters. The angle of elevation of retrodiffused radii is one of these parameters, the importance of which was predicted during the 1960's. The utilization of this parameter, together with the data furnished by a retrodiffusion probe, permitting the observation of all azimuths, is developed in this presentation.

Preliminary results from the measurements of high frequency (HF) backscattered signals from the auroral ionosphere using the Verona-Ava Linear Array Radar (VALAR) system are presented. VALAR is an experimental HF backscatter system capable of obtaining high resolution synoptic mapping of HF signals backscattered from field-aligned electron density irregularities in the auroral ionosphere. The receive system includes a 700 meter long linear array, providing the high azimuthal resolution required for determining the spatial distribution of HF auroral backscatter. Since the completion of the system tests and calibration at the end of 1989, experimental campaigns have been carried out on a near-monthly basis. In this paper, we provide a brief description of VALAR and present preliminary measurements of three types of phenomena: ground backscatter, slant-F, and auroral backscatter. Author (revised)

THE LONGITUDINAL OCCURRENCE OF EQUATORIAL F LAYER IRREGULARITIES
JULES AARONS *In* AGARD, Radiolocation Techniques 12 p (SEE N93-23598 08-32) Nov. 1992 Sponsored by ONR
(AGARD-CP-528) Copyright Avail: CASI HC A03/MF A03

Determining the morphology of F layer irregularities as a function of longitude in the equatorial region is vital for understanding the physics of the development of these irregularities. We aim to lay the observational basis which then can be used to test theoretical models. The question is whether the models are consistent with the morphology as we see it. According to our criteria, the data used should be confined to observations taken near the magnetic equator during quiet magnetic equator during quiet magnetic periods and at times within a few hours after sunset. Anomaly region data should be omitted for studying the generation mechanism. The questions to be answered by proposed mechanisms are (1) why do the equinox months have high levels of occurrence over all longitudes?; (2) why are there relatively high levels of occurrence in the Central Pacific Sector in the Jul.-Aug. period and in the 0-75 degree West Sector in the Nov.-Dec. period?; and (3) why are these very low levels of occurrence in Nov. and Dec. in the Central Pacific Sector and in Jul. and Aug. in the 0-75 degree West Sector? Satellite in-situ data, scintillation and spread F observations are reviewed. The limitation of each data set is outlined particularly as relevant to the bias produced by the existence of thin versus extended layers of irregularities. A cartoon of the occurrence pattern, as we see it, as a function of longitude is shown. Author (revised)

IRREGULAR MEDIA EFFECTS ON RADIOWAVE SIGNALS USED IN NAVIGATION AND POSITIONING SYSTEMS
EZEKIEL BAHAR *In* AGARD, Radiolocation Techniques 12 p (SEE N93-23598 08-32) Nov. 1992
(AGARD-CP-528) Copyright Avail: CASI HC A03/MF A03

Radiowave signals, over a very broad range of frequencies, are used extensively in navigation and propagation systems. These signals that propagate to very large distances from the transmitter across the earth's surface or through the ionosphere are significantly affected by media irregularities. Some of these irregularities are fixed while others fluctuate due to, for instance, the diurnal variations in the ionosphere. The magnitude and phase of CW signals are affected by the medium through which they propagate. Since these effects are frequency dependent, transient (pulsed) signals also undergo distortions and delays, which have a very significant impact on navigation and positioning systems. Thus, when CW signals are used for navigation or positioning, it is necessary to predict the deviations in the phase of the received signals (phase anomalies) due to medium effects. When pulsed signals are used for navigation and positioning, it is necessary to predict the signal delays due to the medium effects. Moreover, for given propagation paths, it is necessary to avoid the use of carrier frequencies that are more prone to signal distortions which make it very difficult to predict the time of arrival of the radio signals. It is necessary to obtain accurate predictions of the received signals as the demands on the navigation system become more stringent. Thus, for most relevant propagation problems, it is not sufficient to use idealized models of the propagation medium. The models that need to be considered consist of layers of nonuniform thickness with varying electromagnetic parameters. Since the ionosphere also needs to be considered, the medium is generally considered to be both inhomogeneous and anisotropic. For these irregular models of the curved earth-ionosphere propagation environment, it is not possible to obtain standard separable solutions for the propagation problem. Furthermore, since the solutions should be valid for a very broad range of radio frequencies, the physical/geometrical optics (high frequency) approach or the small perturbation (low frequency) approach cannot be used in general. In this work, a full-wave approach is described in detail. Radio wave propagation over irregular propagation paths is examined in detail. The phase anomalies and pulse delays and distortions for radio signals transmitted across hills and valleys on the earth's surface or over the oceans and through irregular layered models of the earth's crust and the ionosphere are determined using the full-wave approach. This paper deals with some propagation effects which can influence Single Station Location systems. We consider first, the direct problem which consists of estimating several directions of arrival of the incoming waves. For this purpose and for a given state of the ionospheric medium, the angles of all propagation paths and modes are determined. In a second step, the simplified model of waves coming from the ionosphere which has been developed before, permits us to simulate the behavior of radiogoniometers. We analyze the performance of goniometric systems based upon interferometry, data processing, and space-time processing. Proximity in such propagation modes leads to the addition of a polarization filtering procedure. The problem in reverse consists of locating the emitter thanks to the previous radiogoniometry results. We look at the effect of an imperfect knowledge of the profile, before introducing two SSL methods: the first dealing with vertical sounding results; and the second works from a partial updating profile. We also give an example of an influence of tilt. Author

A CURRENT ASSESSMENT OF SINGLE SITE LOCATING TECHNOLOGY
ROBERT B. ROSE *In* AGARD, Radiolocation Techniques 8 p (SEE N93-23598 08-32) Nov. 1992
(AGARD-CP-528) Copyright Avail: CASI HC A02/MF A03

This paper describes the observed performance of a HF Single Site Locator (SSL) which employs current interferometer technology. One hundred and forty two locations were obtained from non-cooperative targets over a five day period in April 1989. Locations were determined from fast, high resolution azimuth and elevation angle of arrival measurements and a knowledge of the ionospheric reflecting medium. Exact emitter locations were determined post facto with ground truth data from the field units. Five modes of transmission were encountered and the signals were successfully located. Miss distance accuracies varied between 12.5 kilometers to 40.5 kilometers over ranges that varied from 109 kilometers to 526 kilometers. Performance varied as a function of modulation type with SSB voice being the most difficult to prosecute and packet, and burst signals were the easiest to locate. Also, performance varied as a function of range and the relationship of the operating frequency to the maximum usable frequency between the SSL and the target. Author

This paper considers the problem of passive radio location for the case of HF multipath propagation. A new technique is developed for the estimation of interpath time delay applying an eigen based super-resolution spectral estimation method. The technique samples the wavefield received by two spatially separated antennas to compute intersensor delay time for each constituent signal through a normalized eigen cepstral analysis. The intersensor delays and interpath delay are used in concert to estimate the location of the transmitter. The method is applied to experimental data in a preliminary proof-of-concept analysis. The location of an HF transmitter may be derived by either of two methods, depending on what observations of the target transmitter are available. In the traditional approach currently adopted for strategic DF networks, the location is determined by triangulation using Lines of Bearing (LOB) of the signals observed at two or more HF-DF sites. This approach is called the LOB approach. Alternatively, the location may be derived by observations at a single DF site, if the observations are extended to include that of the elevation angle as well as the bearing of the incoming radio waves. Triangulation in the vertical plane containing the observed LOB, using a model of the propagation medium (the ionosphere), leads to an estimate of the position of the target transmitter. This approach is known as the Single Site Location (SSL) method. The success of the LOB approach depends heavily on two or more DF sites being able to hear and process the signals from the target transmitter, as well as on having reasonably favorable geometries. When these conditions are not met, the LOB approach fails. The SSL method, on the other hand, is applicable under almost all conditions. This paper, therefore, compares and contrasts the two approaches to determining the location of an HF transmitter. The relative advantages of the SSL approach are shown to be such that all HF-DF sites should logically be SSL sites. Author

A simple parametric target model fitting algorithm that gives a least squares fit to the observed in-phase and quadrature data across a linear sampled aperture array is outlined. The performance of this algorithm with various simulated signals and noise levels is presented. In particular, it is shown that this approach is quite robust in the presence of noise. The algorithm was developed for the analysis of data obtained on a large HF sampled aperture receiving array operated near Ottawa. An example of this analysis is given. In this instance, a long range signal exhibiting typical ionospheric fading (on individual array elements) is shown to be resolvable into three stable, coherent components spread over a 2.5 degree arc. Recent conflicts have highlighted the benefits of 'soft-kill' electronic warfare (stand off, escort, and self screening jamming), during intrusion into areas protected by Air Defence (AD) radar networks. These conflicts have highlighted the need to protect and supplement the Recognized Air Picture (RAP) with the ability to locate and track the intruding jammers. A Passive Jammer Location (PJL) system, and some of the theory behind it, currently under development at the Marconi Research Center are described. The two basic geometrical techniques for locating unknown emitters, usually termed triangulation and trilateration, are identified. The main problems associated with triangulation techniques, those of target ghosts and ghost resolution in denser scenarios, are discussed and trilateration processing using correlation offered as a solution. The main feature of an operational PJL system is noted as being the need to positively resolve jammer positions, to sub-beam accuracy, in dense jamming scenarios. This includes the 'pop-up' target appearing over the radar horizon and the agile sophisticated jammer. In addition a number of other features are identified which would be desirable in any future NATO PJL system. Over a number of years the UK MoD and GEC-Marconi have undertaken a number of studies relating to PJL architectures and data processing techniques. In 1991 these studies led to the Air Defence Emitter Location Equipment (ADELE) Technology Demonstrator. The objectives of the ADELE program are to demonstrate that the requirements of a PJL system can be met at a price affordable by AD system procurers. Additionally to confirm that the new PJL data processing techniques, developed during these previous studies, perform as predicted during live trials. The main hardware and software modules making up the ADELE demonstrator are discussed including: the multi beam antenna, the resistive matrix beam former, the PJL multi-channel signal sampling hardware, radar interfaces and synchronization, signal and data processing, display and recording, and simulation resources. A year long experimental program was conducted to measure refractive bending, or how much the signal deviates from true line of sight, at low VHF frequencies (29.5 MHz), and to determine whether this deviation or error could be predicted using large scale ionospheric models such as the Ionospheric Conductivity and Electron Density (ICED) program. An experiment to directly measure the angle of arrival of a 29.5 MHz signal from an orbiting satellite was successfully completed. The satellite was in a circular orbit at an altitude of 1000 km. It was shown that refractive errors can be directly related to the electron density along the measurement slant range. Ionospheric disturbances such as sporadic E and ionospheric storms produce large, short term errors that can approach 10 degrees. In addition to day/night variations, seasonal and solar cycle sensitivities were found. The refractive error varied so rapidly with respect to time and space that its prediction with a median value ionospheric code is almost impossible. Author

Strong gradients in electron density associated with sunrise and sunset are a well known feature of the ionosphere and will produce off great circle bearings, particularly if the propagation path is parallel to the dawn or dusk terminator. Measurements were undertaken of the direction of arrival of signals in the range 3 to 23 MHz radiated by a transmitter located at Clyde River in the Canadian Arctic (70 deg N, 70 deg W). The path from this transmitter to the receiving site at Boston, USA, is parallel to the dawn dusk line and consequently systematic changes in bearings are expected to occur. Bearings measured during January 1989 indicate a positive error of a few degrees at around sunrise. As the day progressed the error decreased, becoming zero at local noon at the path mid point. As the dusk approaches, the tilts in the ionosphere are reversed in gradient and there is a smaller negative swing in the mean bearing. The bearing error at dusk is smaller than at sunrise since the ionospheric gradients at this time are less steep. The diurnal swing in the bearing occurs during the winter and equinox periods but is absent (or very small) during summer. This is because the ionospheric gradients in summer are smaller than those at other seasons due to the relatively low values of the F-region critical frequency (foF2) which occur during the summer daytime. It is well known that the auroral zone ionosphere contains steep time varying gradients in electron density which can produce large off-great circle bearings in the direction of arrival of HF radio signals reflected from this region of the ionosphere. Recent DF measurements at a high latitude site indicate that large bearing errors are also observed in signals reflected from the polar cap ionosphere which is generally regarded as being a much less disturbed region than the auroral zone. A feature of these measurements is a large (+ or - 50 deg) quasi-periodic swing in the direction of arrival observed for both short and long propagation paths. These changes in angle of arrival are attributed to reflection from patches or 'blobs' of over-dense plasma which travel with the convection current flow across the polar cap region from dayside to nightside. The periods of large bearing swings are well correlated with the onset of magnetic activity as measured by the Kp index. Author (revised)

The performance of high frequency (HF) direction finding systems is related to the mode content of the received signal and to the signal frequency. In order to fully investigate this effect, an experiment was devised to measure the direction of arrival of oblique ionospheric sounding signals emitted by the worldwide

network of BR Communications chirp sounders. These signals are radiated as a constant sweep chirp signal from 2 to 16 or 30 MHz thus enabling the DF performance to be measured over the full range of frequencies propagating from the chosen transmitter. Simultaneous oblique ionograms are also recorded for the paths of interest in order to determine the mode structure at any frequency. Preliminary tests of the system were undertaken at Ottawa, Canada and Cheltenham, UK with the directions of arrival measured by a wide aperture goniometric DF system. Several interesting features were identified in these measurements. A further measurement campaign was conducted during Apr. 1992 at Alert, a very high latitude site in the Canadian Arctic where very large bearing errors and systematic bearing swings, sometimes in excess of + or - 50 deg, are known to occur.

A computer based model of an automated wide aperture goniometric HF direction finder (type DF6) was developed to investigate the system performance under various simulated signal environments. Several test runs of the model indicated that the original DF6 algorithm could be modified to yield a significant improvement in the measured bearing accuracy and in addition provide a meaningful indication of the quality of the measured bearing. These modifications were implemented and tested at two sites in Canada. A system located in Ottawa was tasked against known transmissions from Halifax, Nova Scotia (950 km) and several hours of data collected. These measurements confirmed that the changes implemented as a result of the computer modeling produced improved bearing measurements. Further tests were conducted at Alert, a very high latitude site in the Canadian Arctic. At this site, the bearings often varied rapidly by several tens of degrees. These latter observations indicated that further changes to the DF algorithm should be made for systems deployed at this high latitude sight. Author

Skywave signals in the HF band experience a plethora of effects which distort them in the time, space, and spectral domains. The ability of a particular measurement to resolve discrete components which faithfully represent a single signal source (i.e., useful for angle-of-arrival estimation) is a somewhat random occurrence given any one fixed integration time. However, the fact that the signal components can be resolved in the spectral domain by our Doppler technique much of the time seems to indicate that there are indeed a finite number of discrete components in any sky wave signal and that the Doppler shift for each component varies independently such that they may be resolvable in the spectral domain.

The method of radiogoniometry from a single sensor operating from the Losquet Island retrodiffusion probe is described. The experimental results of the determination of the azimuth and the elevation of the waves having transitioned through the ionosphere, obtained by well-located emitters, are presented. The measured angles are compared to the results from a propagation model and to the arrival directions calculated by an oblique transposition of vertical ionograms. It is shown that the azimuth in which the emitter is found can be determined with a precision which is that of the accuracy of the measurement, and at elevation, the method allows the measurement of the angles associated with the dominant trajectories even if their performances are limited in the presence of multitrajectories. The Advanced Translator Processing System was developed to provide a low cost alternative to tracking translated GPS signals. It is backwards compatible with the Translator Processing System (TPS) currently used to track Ballistic Missile Translators (BMT) by the US Ranges. NAVSYS has also developed a BMT compatible Translator. A key element of the ATPS is the Preamplifier/Downconvertor (P/DC) module which was developed by NAVSYS to condition the received Translator signal so it can be tracked with a conventional C/A code receiver. This significantly reduces the cost of the hardware by allowing the ATPS to be constructed mostly from off-the-shelf components. The ATPS and Translator were tested against the RAJPO Ballistic Missile and Translator Processing System Specifications. This paper presents the results of tests demonstrating the performance of the ATPS and Translator under different operating conditions. NAVSYS has also developed a Post Test Processing System (PTPS), incorporating the same components, which records the Translator data during the tests. When this data is played back, high-accuracy Time and Space Position <iformation (TSPI) data can be computed on the vehicle even under extreme dynamics. Author

Modern defense systems depend on comprehensive surveillance capability. The ability to detect and locate the radio signals is a major element of a surveillance system. With the increasing need for more mobile surveillance systems in conjunction with the rapid deployment of forces and the advent of technology allowing more enhanced use of small aperture systems, tactical direction finding (DF) and radiolocation systems will have to be operated in diverse operational conditions. A quick assessment of the error levels expected and the evaluation of the reliability of the fixes on the targeted areas bears crucial importance to the effectiveness of the missions relying on DF data. This paper presents a sophisticated, graphics workstation based computer tool developed for the system level analysis of radio communication systems and describes its use in radiolocation applications for realizing such accurate and realistic assessments with substantial money and time savings. The rapid expansion of telecommunication has practically saturated every band of Radio Frequency Spectrum; a similar expansion of electrical and electronic devices has affected all radio communications which are, in some way, influenced by a large amount of interferences, either intentionally or unintentionally produced. Operational consequences of these interferences, particularly in the frequency channels used for aeronautical services, can be extremely dangerous, making mandatory a tight

control of Electromagnetic Spectrum. The present paper analyzes the requirements and the problems related to the surveillance, for civil application, of the Electromagnetic Spectrum between 20 and 1000 MHz, with particular attention to the detection and location of radio interference sources; after a brief introduction and the indication of the advantages of an airborne versus ground installation, the airborne system designed by Alenia in cooperation with Italian Ministry of Post and Telecommunication, its practical implementation and the prototype installation on board of a small twin turboprop aircraft for experimentation purposes is presented. The results of the flight tests are also analyzed and discussed.

The accuracy which is now required in the target approach of the modern missiles, requires the use of several sensors. Inertial systems, GPS when available, and imaging sensors are combined to improve the overall accuracy by the means of filtering and data merging techniques. Several tasks can be realized by the imaging system: targets detection and identification, missile position and motion estimation. The resulting information will be used as command parameters under certain conditions of robustness and accuracy. Our goal is not only to compute these parameters but to specify their domain of usability. Our approach is based on the development of a global simulator. The models of the inertial systems, the information computed by the imaging sensors are combined in a global Kalman filter scheme. The goal is to provide the user with the ability of studying the sensibility of the vision algorithms to some system parameters and external conditions in order to get the best overall accuracy. In the first part of this paper, we present the Kalman filter scheme and the issues involved. In the second chapter, the data that can be obtained from imaging techniques and the associated treatments are presented. We specify what are the constraints and the conditions under which these data can be obtained and study their sensibility to some system parameters. Author (revised)

The complexity of the arrays is directly tied to the number of antennas of which they are composed. The laws of radiation in the far field are well known and are inferred from the law of illumination of the antenna. The worry of the inventor is, as always, to determine, for a number of possible antennas, their spatial partition which assures the most advantageous law of radiation. The electronic orientation of the lobe of the antenna and the functioning within a wide band makes the problem more complex. The desire to obtain a lobe of narrow principal radiation and to limit the amplitude of secondary lobes is always contradictory. Regular structures used fix the characteristics of the diagrams of radiation in which the variations which obey the known laws are less favorable than the optimization of the diagrams. Aleatory structures can be used, but the correct results are not obtained until after multiple attempts, without which it is possible to be assured that the solution kept is the best. Fractal structures give results which one knows determine, a priori, the characteristics. Certain structures take particularly well to the construction of antennas and permit the best adjustment to finesse the principal lobe and remount the secondary lobes. Particular fractal themes permit the regulation of the problems of arrays in 1, 2 or 3 dimensional space. The fractal structures can be obtained by deterministic processes but also by the introduction of aleatory fluctuations around the deterministic model, which result in pseudo-aleatory fractal structures, or models built by totally aleatory processes which result in fractal aleatory models.

The use of techniques of transmission by evasion of frequency or gusts in VUHF in order to fight against conventional ECM systems is more and more widespread. The appearance of rapid goniometric sensors makes the interception and goniometry of these signals possible. The localization of these signals by a conventional system requires that the emission be set on standby. In order to avoid this problem, a system of extraction of the emissions with evasion of frequency and gusts with goniometry before localization is proposed, this being carried out on 'synthetic' emissions calculated from goniometric detections. The calculation of these 'synthetic' emissions requires an algorithm allowing the reconnaissance and the identification of the types of emissions. Beginning with the reconnaissance carried out on several goniometers, emitters are sought which have the same characteristics on the various sensors before carrying out localization by the Cartesian least squares method.

An eigenstructure based, doubly adaptive array processing algorithm is described. This algorithm resolves the differential time of arrival (DTOA) between the direct signal and a delayed replica that arrives over a different ray path. Simulations, using theoretical responses of a circular eight element dipole array, illustrate the resolving characteristics of the algorithm. Author

(AGARD-CP-528) Copyright Avail: CASI HC A02/MF A03

In this work, a new algorithm for multiple emitter direction finding for circular arrays is proposed. The algorithm uses a single snapshot for processing. The observation is first transformed into frequency domain. Then, by using the Fourier series coefficients of pattern of the sensors, it is transformed into a suitable sequence. The linear prediction method is applied to the resulting sequence to determine the direction of arrivals from the zeros of corresponding linear prediction filter. An iterative correction scheme is used to improve the accuracy of the estimates. Computer simulations have been performed to evaluate the performance of the algorithm. It has been observed that the algorithm operates successfully if the array circumference is comparable to the wavelength. Author

This paper presents two examples of low level strategies using multi sensor data fusion, one for bridge extraction, and one for urban area extraction. These extractions are made from a

couple of coregistered Synthetic Aperture Radar (SAR) and SPOT images. These features are very different by their dimensions, their shape, and their radiometry. Thus we can prove the reliability of our approach on various types of features. Our method uses the notion of complementarity of each sensor, and the notion of context in the observed scene. For bridge detection, we first segment water in the SPOT image, to spatially constrain the bridge research in the SAR image. This research is achieved using a correlation method. To detect an urban area, we first use the knowledge that it produces very bright texture in SAR imagery. Thus, the main part of urban backscatters is extracted using an adaptative thresholding which keeps the upper band of the gray level histogram of the SAR image. This mask is then used for classification as a training mask of urban area texture in SPOT image. We determine the non urban zone training set using a distance map of the urban training zone boundaries. Classification is performed with a multivariate Gaussian classifier. The results we obtained are very encouraging, especially if we consider the robustness of the bridge detection method. Author

(AGARD-CP-528) Copyright Avail: CASI HC A03/MF A03

This paper is a product of theoretical and practical work done with geostationary and low earth-orbiting (SARSAT) satellites. Reliability, efficiency and cost considerations have resulted in an all digital implementation with standard processors. The analog signal is represented by complex samples calculated from real sampling with an algorithm based on an original concept. Any telecommunication (or radar) signal is represented by reversible transformations of a sinusoidal carrier. Maximum likelihood synchronization and demodulation must be used and consists of reconstructing the 'best' carrier from the received signal. Depending on the uncertainty level, one tries a certain number of time-frequency hypotheses, and for each hypothesis, one makes optimum estimations of 3 carrier parameters: modulus, phase and frequency. Since one deals with one circular function, it is straightforward to develop the phase, so that phase and frequency are the 2 parameters defining a straight line in the developed phase-time plane. The 2 corresponding estimators are decorrelated. For a terrestrial vehicle, one can have a good estimation of its velocity, and even for a stationary satellite there is an apparent periodical known motion, which can be used to locate the vehicle by a convenient combination of elementary estimations. Of course some frequency spreading, clock stability and delay are necessary, but explicit performance is easy to derive as functions of operational conditions. Analysis of numerical results may suggest useful practical systems. Author

A system for recording Extremely Low Frequency (ELF) noise bursts produced by global lightning activity is described. The location of the source lightning flashes for some 320 such events has been deduced from these data. The range of the sources was found by modelling the data using a least-squares fit to the complex wave impedance obtained from the standard propagation theory applicable to the Earth-ionosphere spherical-shell waveguide. The source bearings were deduced from two orthogonal components of the magnetic field vector using the usual goniometric technique. The source range and bearing serve to locate each source on the surface of the Earth. The data show that the majority of ELF event sources are located in tropical regions, an average of 7.4 Mm away from the observing station situated at 51.14 degrees North, 1.44 degrees West (Geographic). The use of such a system to monitor worldwide thunderstorm activity, so far as this relates to ELF events has been demonstrated. Author

The research of sequences presenting good periodic correlation functions is a subject on which much research has been focussed over a long time. The binary sequences are of particular interest because of their simplicity of generation and of treatment. The W.G. (Wolfmann-Goutelard) sequences presented in this report possess quasi perfect periodic correlation functions, such that outside of the central pic, these functions are null except at one point. It is shown therefore that the structure of W.G. sequences is unique and that it is the result of the interlacing of three periodic sequences. The properties of these sequences are studied and it is shown that the algorithms of determination reduce the complexity of their research. The conditions for the existence, or nonexistence, of these sequences are given and the existing sequences for the lengths $N = 8$ alpha $+ 4$, $N = 16$ alpha $+ 4$, and $N = 32$ alpha $+ 4$ where alpha belongs to Z are given up to $N = 20000$. The symposium dealt with small satellites used for tactical applications that might be of value to NATO. The 11 sessions covered TacSat concepts and needs, aspects of TacSat applications, TacSat system applications, communication concepts, launch systems, spacecraft bus, advanced technology, radar concepts, electro-optics concepts, and two panel discussions. The information generated by the symposium will be used by Working Group 16 to report on the utility of such satellites and applications to meet future NATO needs. This paper addresses the concept of a satellite based system serving the needs of tactical users for direct access to communications and various forms of surveillance. Such a system must take account of the most effective methods for deployment and maintenance during its intended period of operation. In terms of the mission needs, the Tactical Satellite System (TACSAT) is required to provide the services for tactical users over a relatively small region of maybe some 1000-2000 km diameter. Also, the concept is likely to involve relatively short periods of operation of about 3 to 6 months for a typical operation scenario. The paper, therefore, addresses a system concept in which the emphasis is placed on reducing the scale of the logistics involved in the deployment of TACSAT elements and simplifying the ground operations and facilities necessary for the users to gain access to the services provided. This paper addresses the following: (1) the need for 'launch on demand'; (2) the possibility of launches being directly under the control of the area commander; (3) operating concepts for TACSATs, comparing the approach of launch-via-residual-mass as part of a larger mission, not dedicated to the TACSAT mission with the approach of dedicated, launch-on-demand; (4) identification of information flow requirements for TACSAT integrity and status evaluation and for surveillance data recovery; (5) determination of technical and cost drivers influencing the form and cost of ground installation and logistic issues; (6) integration of TACSAT facilities and services with other communications and surveillance systems available to the Tactical Commander; and (7) investigation of techniques

minimize the ground control and data collection overhead.

The National Delegates Board of AGARD, upon recommendation by the Avionics Panel of AGARD, approved in March 1986 the establishment of WG-13 to study satellite communications for NATO under the direction of Prof. Dr. Nejat Ince of Turkey. Some 14 scientists/engineers, from research and industrial establishments of Canada, France, the Federal Republic of Germany, Norway, Turkey, the United Kingdom, the United States of America as well as from International Military Staff of NATO and SHAPE Technical Centre, participated in the work of WG-13. This paper is a brief summary of the studies carried out by the group in the period 1988-1990 on the type of satellite communication systems which NATO can have in the post-2000 era including the critical techniques and technologies that need to be developed for this purpose. The communications capabilities provided by EHF satellites can range from low data rate services (75 to 2400 bps per channel) to medium data rate links (4.8 kbps to 1.544 Mbps per link) depending on the payload configuration. Through the use of EHF waveform standards, the EHF payloads will be compatible with existing and planned EHF terminals. Advanced technologies permit the development of highly capable, lightweight payloads which can be utilized in a variety of roles. The key payload technologies include adaptive uplink antennas; high speed, low power digital signal processing subsystems; lightweight frequency hopping synthesizers; and efficient solid-state transmitters. The focus in this paper is on the signal processing and frequency generation technologies and their application in a lightweight EHF payload for tactical applications. Author

In the area of MILSATCOM, considerable effort is currently being expended on the development of systems operating in the EHF frequency bands and employing onboard processing. Two of the principal advantages of employing these features are that the MILSATCOM system will be capable of increased throughput and will possess increased immunity to jamming and other channel impairments. Most of the previous research and development in EHF MILSATCOM has concentrated on Low Data Rate (LDR) waveforms, for data rates up to 2.4 kbps. In order to meet the requirements for increased throughput, Medium Data Rate (MDR) waveforms are being developed. These systems include data rates up to and including T1. This paper examines the constraints that communicating at MDR data rates places on synchronization and provides an overview of some of the various techniques and algorithms that can be employed for both spatial and time acquisition as well as tracking. Both channel and equipment impairments affecting synchronization are examined. Robust open and closed loop acquisition and tracking algorithms are examined in conjunction with onboard processing techniques. Performance is discussed in terms of SNR, acquisition time, probability of correct acquisition and probability of false acquisition. Tradeoffs in a MILSATCOM system design based on various user requirements are also presented. Author

This paper examines communications coverage from five non-geostationary satellite orbits. These orbits are as follows: circular inclined synchronous; GPS; Molniya 12 and 24 hour; and Tundra orbits. It also shows the increase in propagation loss due to irregular terrain and the foliage loss at mm waves, as well as the combined effect of terrain and foliage on satellite view duration. It is concluded that coverage calculations for EHF satcom earth terminals need to take into account terrain and foliage losses.

A reliable knowledge of radio signal amplitude and phase characteristics is required to design and maintain communications and navigational circuits at VLF and LF. The ability to accurately calculate signal levels as a function of frequency, position, and time is of considerable importance in achieving reliable assessment of communication and navigation coverage. Detailed computer models based on multiple mode waveguide theory were developed. These models were found to produce good comparisons between measurements and calculations of signal variations as a function of propagation distance. However, results can be very sensitive to the ionospheric inputs to these computer models. This paper

presents an overview of the computer model and results of empirical modeling of the propagation medium. Author (revised)

In this paper, we have presented a tutorial overview of ELF propagation. We have also compared the Greifingers simple form approximate expressions (which relate ELF propagation constants to realistic ionospheric conductivity profiles) with experimentally derived results for both daytime and nighttime ambient propagation conditions. The inverse problem has also been considered. We have used the experimentally determined values of effective attenuation rate and excitation factor, along with the modified Greifinger equations, to establish representative ionospheric parameters for each propagation path considered. These parameters include the reflection height h(sub o), the inverse scale height Beta (which is equal to 1/Zeta(sub 0)), and the reference height H of the equivalent exponential ionospheric conductivity profile. We have recently analyzed some of the field strength data taken at the U.S. Navy's four land based ELF monitoring sites (New London, CT; Norfolk, VA; Kings Bay, GA; and Pearl City, HI). Both the daytime and nighttime inferred values of excitation factors and daytime attenuation rates are in good agreement with previous 75 Hz band measurements taken over various propagation paths. However, the summertime nighttime attenuation rates are substantially lower (approximately 0.6 dB/Mm compared to approximately 1.0 dB/Mm). Also, the summertime daytime attenuation rates (approximately 1.25 dB/Mm) are lower than measured during other times of the year (approximately 1.50 dB/Mm). Author (revised)

THE CONE STRUCTURE AND FOCUSING OF THE ELECTRIC FIELD OF VLF AND LF WAVES AT HIGH ALTITUDES OF THE IONOSPHERE
Y. L. ALPERT (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA.) and J. L. GREEN *In* AGARD, ELF/VLF/LF Radio Propagation and Systems Aspects 11 p (SEE N93-30727 11-32) May 1993
(AGARD-CP-529) Copyright Avail: CASI HC A03/MF A03

This paper presents a short review of the frequency and angle dependencies of the electric field radiated by an electric dipole E = E(sub 0)cos(omega)t in a magnetoplasma and detailed results of numerical calculations of (E) in the VLF and LF frequency bands 0.02f(sub b) is less than or equal to F is less than or equal to 0.5f(sub b) in the ionosphere and magnetosphere in the altitude region Z = (800 - 6000) km (F is approximately (4 - 500) kHz and f(sub b) is approximately equal to (1.1 to 0.2) MHz is the electron gyro-frequency). The amplitudes of the electric field have large maxima in four regions: close to the direction of the Earth magnetic field line B(sub 0) (it is the so called Axis field E(sub 0); in the Storey E(sub St); Reversed Storey E(sub RevSt); and Resonance E(sub Res) Cones. The maximal values of E(sub 0), E(sub Res), and E(sub Rev ST) are the most pronounced close to the low hybrid frequency, F is approximately F(sub L). The flux of the electric field is concentrated in very narrow regions, with the apexes angles of the cones delta(beta) is approximately (0.1 - 1) degree. The enhancement and focusing of the electric field increases with altitude starting at Z is greater than 800 km. At Z is greater than or equal to 1000 up to 6000 km, the relative value of E, in comparison with its value at Z equals 800 km is about (10(exp 2) to 10(exp 10)) times larger. Thus, the flux of VLF and LF electromagnetic waves in the Earth magnetoplasma produces and is guided by very narrow pencil beams, similar, let us say, to laser beams. Author (revised)

The Research, Development, Test, and Evaluation (RDT&E) division of the Naval Command, Control and Ocean Surveillance Center (NCCOSC), and its predecessors, Navy Electronics Laboratory (NEL), Naval Electronics Laboratory Center (NELC), and Naval Ocean Systems Center (NOSC), have had a continuing program to develop a reliable VLF/LF communications coverage prediction capability for the U.S. Navy. This involves the measurement of field intensity of many communication stations, the development of propagation models to fit the data measured, and the validation of these models to verify predictions for all seasons world-wide, including possible solar cycle effects. During the current campaigns, data were recorded using various platforms including numerous aircraft, six ships, three submarines, and up to 28 fixed sites since 1981. Currently, data are being recorded aboard two ships and at seven fixed sites. An attempt is made to maintain an overall root-mean-square (rms) accuracy of 0.5 dB, with system calibration and stability measured to the order of 0.1 dB ring. The goal for the model under development is to fit these data and extrapolate predictions to other propagation conditions to within 1 dB. This was a challenging task where local environmental effects can cause significantly larger perturbations. A review of the literature is presented summarizing and comparing methods and techniques used by other researchers in the field. This is followed by discussion of the commercial equipment used, the calibration and recording procedures followed, a comparison of results obtained simultaneously using various platforms and sites, and an estimate of the overall accuracy/reliability of the data obtained. VLF PROPAGATION MEASUREMENTS IN THE CANADIAN ARCTIC
WILFRED R. LAUBER and JEAN M. BERTRAND *In* AGARD, ELF/VLF/LF Radio Propagation and Systems Aspects 12 p (SEE N93-30727 11-32) May 1993
(AGARD-CP-529) Copyright Avail: CASI HC A03/MF A03

For the past three years, during a period of high sun spot numbers, propagation measurements were made on the reception of VLF signals in the Canadian Arctic. Between Aug. and Dec. 1989, the received signal strengths were measured on the Canadian Coast Guard icebreaker, John A. MacDonald in the Eastern Canadian Arctic. Between Jul. 1991 and Jun. 1992, the received signal strengths were measured at Nanisivik, Baffin Island. The purposes of this work were to check the accuracy and estimate variances of the Naval Ocean Systems Center's (NOSC) Long Wave Propagation Capability (LWPC) predictions in the Canadian Arctic and to gather ionospheric storm data. In addition, the NOSC data taken at Fort Smith and our data at Nanisivik were used to test the newly developed Longwave Noise Prediction (LNP) program and the CCIR noise predictions, at 21.4 and 24.0 kHz. The results of the work presented and discussed in this paper show that in general the LWPC predicts accurate values of received signal strength in the Canadian Arctic with standard deviations of 1 to 2 dB over several months. Ionospheric storms can gauge the received signal strengths to decrease some 10 dB for a period of several hours or days. However, the effects of these storms are highly dependent on the propagation path. Finally the new LNP atmospheric noise model predicts lower values of noise in the Arctic than the CCIR model and our limited measurements tend to support these lower values. Author (revised)

The coverage area of a VLF transmitting station, located in the northern part of Germany, is analyzed. In order to predict the

receiving skin depth for the complete operation area of the VLF station, some investigations were made in theoretical propagation models. Then a computer program based on the wave guide mode theory was implemented. To verify the validation of the theoretical model, measurements of field strength in some specific areas were carried out. The first part of the paper is concerned with a description of the theoretical approach of the coverage analysis. The second part describes some properties of the operation area and gives in detail results from measurements. Finally, a comparison of theoretical and measured data then shows the quality of agreement between theory and praxis.

VLF Radiowave propagation provides one of the few viable tools for exploring the properties of the lower D-region ionosphere. Conversely, VLF communications coverage analysis and prediction is directly dependent on the quality of models for the D-region ionosphere. The VLF Omega navigation signals are an excellent and under-utilized resource for conducting D-region research in direct support of VLF communications. Stations are well placed for investigating polar, mid latitude, and equatorial phenomena. Much can be learned by fully utilizing the very stable signals radiated at five frequencies, available from each of the eight transmitters, and taking full advantage of modal structure. While the Omega signals, 10.2 to 13.6 kHz, are well below the VLF communications band, we contend that much of the knowledge gained on D-region characteristics can be directly applied at the higher frequencies. The opportunity offered by Omega needs to be exploited. With the Global Positioning System (GPS) coming onboard as the prime means for global navigation, pressure is mounting to phase out Omega. In this paper we describe how we are using Omega along with computer codes of full wave VLF propagation, provided to us by the U.S. Naval Ocean Systems Center (NOSC), for ionosphere research and by example illustrate the potential for other investigations. This paper describes certain characteristics and statistics of the Trimpi effect, as observed near to and equatorward of the Antarctic Peninsula region, inferred using data from specially designed narrowband OPAL (Omega Phase and Amplitude Logger) receivers deployed in 1989 at Faraday and Halley stations, Antarctica. The amplitude and phase of signals from four Omega VLF transmitters were recorded in each Omega segment (8 segments per 10 s). A 12 month data set was scanned for Trimpi events which, however, were observed on only three of the eight paths, namely Hawaii-Faraday, Argentina-Faraday, and Argentina-Halley, due to inadequate signal-noise ratio on the other paths. The great majority of the approximately 3500 observed events occurred at night. For the all-sea, Hawaii-Faraday path at night, with a single mode dominant at the receiver, lightning-induced electron precipitation (LEP) was inferred to be occurring up to approximately 1.8 Mm from Faraday. A scatter plot of Trimpi amplitude versus phase for this path is interpreted to infer that LEP regions responsible for the events occurred mostly in the L-range 2-3, with the horizontal size of an affected region in the ionosphere being typically 50 km latitudinally and 200 km longitudinally. In recent years, at least two different ways in which energy from lightning discharges couples into the lower ionosphere and the radiation belts have come to the fore. In this paper, we briefly review these recent results especially from the point of view of their effects on VLF/LF radio propagation in the earth-ionosphere wave guide. We separately discuss two different mechanisms of coupling, namely lightning-induced electron precipitation, and lightning-induced heating and ionization of the lower ionosphere. We also discuss a planned active VLF wave-injection experiment designed to investigate ionospheric heating by VLF waves under controlled conditions and to generate ELF waves by modulated VLF heating. Low frequency (30-300 kHz) radio waves can propagate to great distances with little attenuation in the cavity formed by the earth and the ionosphere. Because of the relatively high frequency at LF, many active propagation modes can occur between the transmitter and receiver. Changes in the ionospheric conductivity or reflection height can influence the phase and amplitude of these modes and, hence, produce mutual interference. Because of these interference effects, the propagation is less stable than at VLF and the received field strength becomes more difficult to predict. In the present investigation, the WAVEHOP program was employed in conjunction with a range of ionospheric models to estimate the receiver field strength over a number of experimental paths. The predicted values were compared with those measured in an attempt to validate the ionospheric models and the method of calculation. Author (revised)

ELF PROPAGATION IN DEEP AND SHALLOW SEA WATER
C. P. BURKE and D. LLANWYNJONES *In* AGARD, ELF/VLF/LF Radio Propagation and Systems Aspects 8 p (SEE N93-30727 11-32) May 1993 Sponsored in part by Defence Research Agency

In this paper, electromagnetic wave propagation at Extremely Low Frequencies (ELF) in deep and shallow sea water is considered. The term 'ELF' is used here somewhat loosely to refer to the frequency band 0-3 kHz. The radiation source is considered to be located in the sea water and is taken to be a horizontal electric dipole (HED) or a vertical electric dipole (VED). For the deep water ease, a comparison is made between results computed using complex image theory and results calculated using the full Sommerfeld integral formulation. Both of these formulations include the lateral waves which propagate along the air-sea interface. Moving on to the case of shallow water, there are two lateral wave modes of propagation-lateral waves which propagate on the sea surface and along the seabed. These modes are included by numerical evaluation of the Sommerfeld integrals which appear in the complete solution. We also compare the relative efficacy of subsurface horizontal electric dipoles and vertical electric dipoles as radiators. For the case of zero frequency (dc), the Sommerfeld integrals simplify considerably enabling the fields to be evaluated as the sums of infinite series. This dc formulation leads to much reduced computation time. Finally, the effects on propagation of long-wavelength water gravity waves or tides on the surface of the sea are examined by considering these waves as a perturbation to the sea-air interface. COMPARATIVE STUDY OF UNDERSEA FIELDS PRODUCED BY VARIOUS DIPOLES
G. ANNAERT and A. BAREL *In* AGARD, ELF/VLF/LF Radio Propagation and Systems Aspects 9 p (SEE N93-30727 11-32) May 1993
(AGARD-CP-529) Copyright Avail: CASI HC A02/MF A03

ELF/VLF/LF-radiation by electric or magnetic dipoles located above or on the surface of the earth or sea is investigated from the exact Sommerfeld potentials. Due to the nonzero conductivity of the ground or sea water, the waves are strongly attenuated and only a small near field can be effectively used for communication in a low frequency range. The Fresnel coefficient approximation technique, which presumes a planar plane wave propagation, is correct in the far-field but loses great accuracy in a region close to the radiator. It is the purpose of this paper to review the electromagnetic propagation in layered media based on the rigorous spectral domain method. This theory expresses the Hertz potentials, either of the magnetic type A or the electric type F, in terms of Sommerfeld integrals. A communication range, as the maximum depth at which satisfactory signal reception is still possible, is derived in function of ground parameters, frequency, and dipole orientation. Author (revised)

This paper describes a method of predicting the depth performance of a VLF/LF (Very Low Frequency/Low Frequency) communications system for submarine reception. The method uses a Long Wave Propagation Capability program which includes parameters of the system to be considered, such as transmitter power, aerial, and receiver sensitivities. Results from an analysis for a particular communications system are presented including an audio visual format to show the expected variations in depth performance with reference to operational frequency, transmitter power, time of day and year, and the signal to noise requirements for the system. The analysis method is flexible and could be adapted for similar communications systems. Author (revised)

A computer model that predicts both horizontally and vertically polarized noise in the ELF to LF band (10 Hz-60 kHz) is described. Since naturally occurring radio noise in this band is produced by lightning, and propagates to the receiver via the earth-ionosphere waveguide, the model starts with average lightning flash density data which it turns into radiated power for horizontal and vertical noise. Adjustments are made to the radiated power to account for seasonal and latitudinal differences in the lightning processes. The noise power is then integrated over fairly large geographic areas into horizontal and vertical equivalent noise transmitters. The power radiated from each of these transmitters is propagated to the receiver location using standard anisotropic long wave propagation algorithms and well-known models of the earth-ionosphere waveguide. From the received power, the model predicts RMS noise, standard deviation, voltage deviation VD, and the amplitude probability distribution of the noise for both polarizations. Since the model is based on theory, it can also predict these parameters under disturbed ionospheric conditions. The model's agreement with data is demonstrated.

Within the framework of the TSS1 (Tethered Satellite System)-Project, a measurement program on the electromagnetic background noise was performed. This program, called OESEE (Observation on the Earth Surface of Electromagnetic Emissions), intends to carry out a number of passive detections of possible emissions by the orbiting tethered system. From theoretical considerations on the cold plasma theory in the ionosphere, the expected frequency band of these emissions should be in the order of about 1 Hz up to 60 Hz. In order to design an optimal receiver of such a signal, the noise statistical characteristics have to be taken into account. From the literature, it was shown that this noise is characterized, from the statistical viewpoint, by a non-gaussian and non-stationary behavior. This paper outlines some recently proposed applications of non-gaussian and non-stationary signal processing techniques which can be usefully applied to ELF (Extremely Low Frequency) electromagnetic noise characterization for detection and parameter estimation purposes. Some simulation examples are presented together with some results obtained from experimental data of natural background noise in the ELF range recorded at Canary Islands as a preliminary test of the TSS1 mission. The TSS1 (Tethered Satellite System) is a NASA/ASI (Agenzia Spaziale Italiana) research project.

We report simultaneous measurements of ELF/VLF radio noise (10 Hz-32 kHz) at three high latitude locations (Thule and Sondrestromfjord, Greenland; and Arrival Heights, Antarctica) during a number of moderately large and large solar particle events (SPE's) including some of the largest that have been observed during the last three decades. Thule is close to the center of the northern polar cap and thus the ELF/VLF noise signals reaching it are particularly exposed to the ionospheric effects of the SPE's, whereas the ELF/VLF noise signals at Sondrestromfjord and Arrival Heights, which are located closer to their corresponding auroral zones, should be less affected. These general expectations are supported by the results of our measurements, which show major changes occurring in the Thule noise statistics following the start of the polar cap absorption (PCA) caused by the SPE's and smaller changes at Sondrestromfjord and Arrival Heights. The changes depend markedly on the frequency of the noise signals. At Thule, for frequencies in the approximate range 250 Hz to 1.5 kHz, the diurnal variation in the ring noise amplitudes is typically suppressed during the 2-3 days following the start of the PCA, and in most of the examples we have examined there tends to be a decrease in the average amplitude. Nevertheless, increases can occur. Following the event of 12 Aug. 1989, the noise amplitudes increased by as much as 10-15 dB. For most other frequencies in the range 10 Hz-32 kHz there is little change in the noise statistics. However, in the range 3-10 kHz there tends to be a marked decline in the ring noise amplitudes at Thule in the 24 hours following the start of the PCA, after which there is a rapid recovery to the undisturbed levels. At Sondrestromfjord and, to a lesser extent, at Arrival Heights, the most marked change appears to be the suppression of the diurnal variation noise peaks and thus

lower average noise amplitudes in the 2-3 days following the start of the PCA. Author (revised)

A 16-bit digital spectrum analysis system was designed and built to provide measurement capabilities not currently available in commercial systems. The system provides the wide dynamic range necessary to observe very weak signals in the presence of strong signals. Large sample size allows for high frequency resolution. System outputs include spectral densities, amplitude probability distributions, diurnal amplitude variations, and time domain plots. Measurements were made to characterize the ELF/VLF H-field noise environment in a sampling of office buildings. These include two buildings in New York City and two Denver office buildings. Measurements were made for all hours of the day and include business day and weekend coverage. Results reveal a complicated signal environment. Associated with the power distribution frequencies were strong odd harmonics with higher harmonics evident into the kilo Hertz range; other man-made noise components were also evident. Author

Very Low Frequency (VLF) transmitting antenna design is a specialized field of engineering that requires the combined skill of radio, civil, and mechanical engineers. The antenna systems used for this band (15-30 kHz) are enormous structures. Vertical radiators with very extensive top-loading (non-radiating top-hats) are necessary because the electrical height of practical towers is small. For tower heights of 300-450 meters (1000-1500 feet) the electrical heights are only fifteen to forty-five one thousandths of a wavelength. This presentation discusses the following topics: antenna design concepts, antenna fundamentals, tools for antenna modeling, a mini-study of conventional antennas, multiple tuned antenna systems, and a comparison between performance (measured and predicted) for multiple tuned antennas vs. single tuned antennas. This study considers the use of an array of VLF antennas distributed throughout the UK, instead of a single, high powered antenna, for submarine command broadcasts. Such an array offers survivability and environmental advantages. The coverage of the array would, however, not be omni-azimuthal, but would have nulls every few degrees as a result of the interference between the signals from the individual antennas. The study investigates the effect on the array coverage of a number of impairments (operating frequency, phase and frequency errors, and antenna loss) and discusses the advantages and disadvantages of steering the main beam to the receiving platform. Consideration is also given to how the received signal will be distorted depending on the location of the receiving platform. It was concluded that a VLF array would not be suitable for providing wide area continuous and assured communications. Author (revised)

As is well known, the far field pattern of an aperture is related to a distribution of radiating sources by the Fourier Transform. In this paper, we show that it is also possible to use a Fourier Transform to perform the analysis and synthesis of short antennas. In this way, we can easily have both the analytical and graphical representation of the antenna pattern and the errors that we make with the usual approximating models. It is also possible to make use of know how from the field of signal processing to perform the analysis and synthesis of the radiation pattern. All the theory is based on the Theorem of the Small Complex Translation meaning that we can represent all the current distribution on the antenna by complex translations of an infinitesimal element of current. The correspondent pattern can be found using an adequate spatial variable representation. Author (revised)

This paper presents a numerical procedure which can be effectively used for the analysis/design of a very-low frequency capacitive antenna system on complex platforms and for charge distribution computation. The 'quasi static' radiation problem was solved by means of the corresponding electrostatic solution, by using a Method Of Moments (MOM) procedure. Pulse basis functions, defined on surface patch domains, and the point-matching test procedure are used in conjunction with a powerful postprocessing numerical tool. Given the platform model, the postprocessing tool allows us to analyze all possible antenna

configurations by running the MOM computer code only once. The following parameters can be evaluated: (1) antenna radiation pattern; (2) antenna Norton equivalent circuit, from which the effective voltage at the input of the receiver can be evaluated; (3) induced charge distribution; and (4) scattered electric field distribution near the platform. The proposed solution is particularly useful for applications where the criticality of the structure requires a peculiar attention in defining structural elements that constitute the 'electrical doublet' (conformal antenna). An orbital emplacement for the transmitter and the antenna of a communications link at ELF (30 to 300 Hz) and VLF (3 kHz to 30 kHz) to submerged submarines has been considered since the very inception of the space age. However, only recently has space technology reached a sufficient level of maturity for system designers to undertake serious studies of this link configuration. The optimistic outlook stems from recent space technology developments, such as the design and construction by NASA of long orbiting tethers, and the testing, onboard Shuttle Orbiter ATLANTIS, of the first spaceborne 20 km metal wire. This is known as the Tethered Satellite System-1 (TSS-1), a space mission that might be possibly followed by other flights, with tether lengths that could reach 100 km. Once deployed at a height of, say, 300 km, from a Shuttle Orbiter, or from another suitable platform, a long, thin tether aligns itself along the local vertical by virtue of the gradient of the Earth gravity field. If made of metal, the tether can function as a VED (Vertical Electric Dipole) transmitting antenna at ELF and VLF. Author (revised)

MICROWAVE PROPERTIES AND SYSTEMS OVERVIEW
RONALD LAWRENCE *In* AGARD, Rocket Motor Plume Technology 35 p (SEE N94-15217 03-20) Jun. 1993
(AGARD-LS-188) Copyright Avail: CASI HC A03/MF A03

Of particular significance to the operational success of a missile using microwave communications is the interference introduced by the rocket exhaust plume. As a hot and turbulent gas stream the exhaust has electrical properties that can seriously degrade guidance and tracking. Also present is the potential for missile detection offered by energy scattered from microwave signals impinging upon the plume to present a radar cross section, and an exhaust signature from inherent emission sources within the plume. This paper presented in AGARD Lecture Series 188, follows from AGARD Advisory Report 287 submitted by Propulsion and Energetics Panel Working Group 21 entitled 'Terminology and Assessment Methods of Solid Propellant Rocket Exhaust Signatures.' It provides a description of microwave propagation through a rocket exhaust, the cause of signal attenuation, and the generation of phase and amplitude sideband noise. Consideration is given to the effects of missile flight velocity and altitude. Diffraction and refraction processes are discussed, particularly in relation to plumes containing high density concentrations of free electrons. Radiation sources, mainly at millimetric wavelengths, are included together with signature implications. The effects of exhaust interference with communications is examined from a system point of view and some methods of relief from the interference are considered. Author (revised)

The electromagnetic radiation originating from the exhaust plume of tactical missile motors is of outstanding importance for military system designers. Both missile- and countermeasure engineer rely on the knowledge of plume radiation properties, be it for guidance/interference control or for passive detection of adversary missiles. To allow access to plume radiation properties, they are characterized with respect to the radiation producing mechanisms like afterburning, its chemical constituents, and reactions as well as particle radiation. A classification of plume spectral emissivity regions is given due to the constraints imposed by available sensor technology and atmospheric propagation windows. Additionally assessment methods are presented that allow a common and general grouping of rocket motor properties into various categories. These methods describe state of the art experimental evaluation techniques as well as calculation codes that are most commonly used by developers of NATO countries. Dominant aspects influencing plume radiation are discussed and a standardized test technique is proposed for the assessment of plume radiation properties that include prediction procedures. These recommendations on terminology and assessment methods should be common to all employers of plume radiation. Special emphasis is put on the omnipresent need for self-protection by the passive detection of plume radiation in the ultraviolet (UV) and infrared (IR) spectral band. Author

The increasing sophistication of surveillance systems, both civilian and military, has generated a great deal of interest in techniques of multi-target tracking and sensor integration. To help SHAPE and the NATO Air Command and Control System (ACCS) Management Agency (NACMA) to specify and implement the ACCS surveillance subsystem, in particular in the areas of data fusion and identification, the SHAPE Technical Center (STC) is currently developing an ACCS Surveillance Exploratory Prototype (ASEP) as an element of its new integrated testbed. The purpose of the ASEP is to demonstrate the feasibility and operational benefits of future air picture generation systems. The significant difference between this advanced system and currently available systems is that ASEP will provide better tracking continuity, more accurate estimates of track positions, velocity, acceleration, and additional information on targets. The provision of this information on air targets is also of great importance for civil ATC systems, especially in view of growing requirements for ATC planning, conflict alert and conflict resolution. The use of multiple sensors and sources requires the fusion of different types of data, including sensor reports containing measured attributes such as the target type and other target features. Since advanced fusion algorithms are using kinematic data as well as attribute data for the identification process, the majority of all air targets can be identified automatically. This paper gives an overview of the following components that are implemented in the ACCS Surveillance Exploratory Prototype at STC: scenario generation and sensor simulation; real-time multi-sensor tracking; real-time radar data integration; external track and flight plan data integration; and air picture presentation on a Surveillance Workstation using new human-computer interface (HCI) techniques. This publication reports the papers presented to a specialists' meeting held by the Electromagnetic Wave Propagation Panel at its Spring 1993 meetings. The topics covered include: the effects of natural obscurants (haze, clouds, fog, rain, snow and dust) on system performance; the effects of man-made smokes, battlefield-induced smokes and enhanced scintillation on system performance; atmospheric effects on target and background signatures, and target to background contrast; multispectral camouflage -- weather-related propagation effects on camouflage and obscurants effectiveness and contrast reduction, and theoretical and/or experimental evaluation of camouflage effectiveness; systems mitigation aspects -- methods to mitigate the above-mentioned factors, e.g., image processing, sensor fusion, tactical weather intelligence, and tactical decision aids. For individual titles, see N94-30496 through N94-30514.

The possibility of exploiting measurements obtained through a C-band dual polarization radar is examined, as an auxiliary tool for the planning of radio relays operating at millimeter frequencies. C-band weather radars, though featuring several advantages related to their cost and reduced size, provide partially attenuated rainfall measurements with respect to their S-band counterparts. However, good reliability of rainfall rates based on C-band dual polarization measurements is achieved after proper processing based on iterative procedures for propagation attenuation due to rain. A simulation program has been utilized to provide synthetic rainfall and C-band dual polarization reflectivity data related to several storms, corresponding to different meteorological conditions. Simulated data, after proper correction of radar data, have been utilized to evaluate path attenuation statistics useful to predict fading at millimeter frequencies and related outage probability. Results show that a C-band radar can be profitably exploited for the purpose, prediction being feasible under different space-time rain patterns. On the other hand, the analysis has shown that differential reflectivity is not so essential for the aforementioned purpose as absolute reflectivity, even if it could be utilized with success in real contexts for the identification of hydrometeors (hail, graupels, wet snow) other than rain, which may be responsible for more pronounced scattering and absorption phenomena. Propagation characteristics of the atmosphere are modeled for the frequency range from 1 to 1000 GHz (1 THz) by the modular millimeter-wave propagation model MPM. Refractivity spectra of the main natural absorbers (i.e., oxygen, water-vapor, suspended droplets and ice particles) are computed from known meteorological variables. The primary contributions of dry air come from 44 O2 lines. Results from extensive 60-GHz laboratory measurements of the pressure-broadened O3 spectrum were applied to update the line data base. The water-vapor module considers 34 local H2O lines plus continuum contributions from the H2O spectrum above 1 THz, which are formulated as wing response of a pseudo-line centered at 1.8 THz Cloud/fog effects are treated with the Rayleigh approximation employing revised formulations for the permittivities of water and ice. The influence of the Earth's magnetic field on O2 absorption line becomes noticeable at altitudes between 30 and 120 km. Anisotropic medium properties result, which are computed by the Zeema propagation model ZPM. Here the elements of a complex refractivity tensor are determined in the vicinity (plus or minus 10 MHz) of O2 line centers and their effect on the propagation of plane, polarized radiowaves is evaluated. A spherically stratified (0-130 km) atmosphere provides the input for the codes MPM and ZPM in order to analyze transmission and emission properties of radio paths. Height profiles of air and water vapor densities and of the geocoded magnetic field are specified. ZPM predicts polarization- and direction-dependent propagation through the mesosphere. Emission spectra of the 9+ line (61150 plus or minus 3 MHz) for paths with tangential heights ranging from 30 to 125 km are consistent with data measured by the shuttle-based millimeter-wave limb sounder MAS. THE INFLUENCE OF THE EVAPORATION DUCT ON THE ANGLE OF ARRIVAL AND AMPLITUDE OF THE BACKSCATTERED SIGNAL FROM TARGETS LOW ABOVE THE SEA
H. SITTROP, H. GRAVESTEIJN, and H. J. M. HEEMSKERK *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation 13 p (SEE N94-30495 08-32) Nov. 1993
(AGARD-CP-542) Copyright Avail: CASI HC A03/MF A03

The impact of multipath and atmospheric refractions on the amplitude, the apparent Radar Cross Section, RCS(sub a), and the Angle of Arrival, AOA, of low altitude target radar backscatter at 9.4 GHz, can be described as typical for 3 ranges, and 3 duct

height intervals, i.e., respectively 6, 10, and 19 km, and 10 m, 10-18 m and 18-26 m. The targets are tri-hedrals mounted on poles injected into the sea-bed at the above mentioned ranges. Sensor height is 23 m above normal low sea-tide and the target heights vary from 4.5 m to 8 m depending on the sea-tide. Whereas the RCS(sub a) and the AOA show opposite behavior at 10 km and at 19 km, i.e. and RCS(sub a) decrease and an AOA decrease at 10 km, both for duct heights of 18-26 m, the opposite occurs for duct heights of 10-18 m. However, in this latter case no dramatic differences occur with respect to the AOA. At the 6 km range the RCS(sub a) is persistently larger (4-8 dB) than the free-space RCS(sub o), for duct heights less than 10 m, whereas the AOA is predominantly negative for all recorded duct heights (0-26 m). On the other hand the RCS(sub a) at this range reduces from circa +6 dB to -6 dB relative to RCS(sub 0) for increasing target height and duct heights of 10-26 m. This characteristics target/duct height behavior may introduce misleading information about the type of target. Particularly at long ranges (19 km) and target heights of circa 6 m, the RCS(sub a) may be -20 dB with respect to the free-space RCS(sub o), and the AOA +.6, for duct heights of 10-26 m. Detection probability reduces significantly, and if the target is detected, the height position is entirely wrong, i.e. circa +200 m, whereas the target is only 6 m above sea. At duct heights between 10-18 m the RCS(sub a), and hence the detection probability increases at 19 km. On the other hand this RCS(sub a) can be 10-20 dB lower at 10 km, particularly at target heights between 4-6 m. A lost tract at 10 km may therefore be possible, if detection was just feasible at 19 km at these duct heights. PCPEM predictions and measurements at 5.8 km show in general a fairly comparable trend for target heights between 6-7 m, however, for duct heights of 0-18 m, a too high RCS(sub a) is predicted and for the observed duct heights of 18-25 m a too low RCS(sub a). Within the region of transition from a too high to a too low prediction, comparable values are observed. For target heights between 5.5-6 m PCPEM predicts too large values for all duct heights. A fog system capable of producing water droplets with diameters between 5 and 40 micrometers was used for multispectral transmittance measurements. Measurements were conducted at an arid, desert field location on the White Sands Missile Range, New Mexico. The fog system consists of a supply of local tap water, 50 gallon holding barrels, high pressure hoses and connectors, and an array of specially designed spray nozzles. The spray nozzles have precision made .006-inch diameter orifices. Water under 1000 psi of pressure is forced through the small orifice and impacts onto a curved metal pin causing droplet formation and dispersion. Droplet size distribution of the man-made fog were measured by forward scattering particle-measuring instruments. The advantages of using the fog generation system are low energy requirements, high rates of droplet production, environmentally safe dispersion, and commercial availability. Transmittance measurements were taken by a Multi-Path Transmissometer/Radiometer (MPTR). The MPTR is capable of obtaining transmittances at .4-.7 micron, 1.0-1.1 micron, 3.5-4.8 micron, and 7.9-12.3 micron spectral bands. Results will be presented on transmittance comparisons between the different wavelength bands during varying fog density conditions. The transmittance data from the line of sight were tested for optical depth linearity in the various wavelength bands. Author

Transmittance in the visible and thermal infrared may be estimated from a variety of in-situ and remote techniques using ground-based or airborne sensors. However, estimation of transmittance in the troposphere from data gathered by sensors on space platforms remains a problem, especially over land surfaces. This paper presents two preliminary methods: one to compute visibility using changes in contrast from a series of luminance images or measuring changes in the nonzero frequency amplitudes from the associated frequency domain images, and the other to calculate thermal infrared transmittance over a horizontal, vertical, or slant path that uses estimates of precipitable water from satellite data, combined with sounding data from satellite or other sources. AN EXPERIMENTAL AND COMPREHENSIVE METHOD TO MEASURE EMISSION CHARACTERISTICS [UNE METHODE EXPERIMENTALE ET GLOBALE DE MESURE DE L'EMISSIVITE]

R. MARCHAL *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation 8 p (SEE N94-30495 08-32) Nov. 1993 In FRENCH

(AGARD-CP-542) Copyright Avail: CASI HC A02/MF A03

The characteristics of emission may be of thermal infrared multispectral processes: either through direct measurements on the emitted flux, which are compared to a reference black body, or through measurements on reflectivity and application of the Kirchoff laws. Both approaches have advantages and drawbacks according to the type of emission characteristics that are studied. The method which is used in this study uses the first principle: it concerns itself with relatively high levels of emissions (greater than 0.5), which are directional and controlled by a given sensor. In order to maximize the precision of measurements, testing respects the following conditions: (1) lessening of residual parasite flux, through the use of low emission materials and a cooled diaphragm, thus creating a confined enclosure; (2) taking into account the residual parasite flux, through models of radiation exchange within the enclosure; (3) assessment of the homogeneity in temperature of both the sample and the reference materials; and (4) calculations on the confidence levels, in function of the variances in the beginning parameters. This use of models, added to technical advances, make it possible to build a very inexpensive test site, at least as far as specific purchases were concerned. Several comparative measurements showed that the range of measurable emissions goes from 0.5 to 1, with an absolute confidence level of 0.05 to 0.02, according to the material. The best performance was obtained when highly emissive and highly heat conductive materials were used. Transl. by FLS

During 1993, Canada, France, Germany and the United Kingdom will be participating in the Smoke and Obscurants Countermeasures Materials Evaluation Tests (SOCMET). The tests will be carried out under the auspices of the NATO Army Armaments Group, AC/225, Panel VI, Sub-Panel 7 whose interests include multispectral smoke screening systems. The tests will comprise two sets of trials; one under cold climate conditions in Quebec, Canada, during February/March 1993 and the other in temperate conditions in Bourges, France during September 1993. This paper provides an insight into the management and aims of SOCMET. The evaluations will be seeking to identify candidate materials which create effective obscurant screens in the visible,

infrared and millimetric bands of the electromagnetic spectrum. These materials will be disseminated through a range area dispersal. A key element of the trials will be the evaluation of field test instrumentation which may eventually lead to the development of standardized evaluation techniques. Following the trials, a scientific workshop will be held to review the results. A final report will be presented to NATO which will form the basis of future collaborative developments on multispectral screening systems leading towards standard NATO documentation on smoke and obscurant systems. This paper provides an unclassified overview of the U.S. Army program that collects and disseminates information about the effects of battlefied smokes and obscurants on weapon system performance. The primary mechanism for collecting field data is an annual exercise called SMOKE WEEK. In SMOKE WEEK testing, a complete characterization is made of the ambient test conditions, of the electromagnetic radiation propagation in clear and obscured conditions, and of the obscuring cloud that the particles that comprise the cloud. This paper describes the instrumentation and methodology employed to make these field measurements, methods of analysis, and some typical results. The effects of these realistic battlefield environments on weapons system performance are discussed generically. Author

Target detection using passive electro-optic devices operating in the 8 to 14 micron band is often limited by background clutter. A possible method of overcoming this limitation may be to use the polarization content of the image to discriminate between man-made targets and natural background. Laboratory measurements are presented of the polarization state of 10 to 6 micron radiation reflected from, and emitted by, a range of materials. It is concluded that elliptical polarization is not of primary importance and that measurements of the degree of linear polarization appear to provide useful discrimination between man-made objects and 'natural' ones. In order to assess very accurately the performances of millimeter wave imaging passive systems, efforts have been made towards the development of a straightforward easy to use computer code. This simulation model has been used to evaluate the influence of meteorological conditions on radiometric contrasts. The following parameters are studied: frequency, terrain emissivity, and radiometer position. A first set of simulations is done in the scatter-free atmosphere assumption. Then scattering by hydrometeors is taken into account. In each case, ground surface discrimination by their radiometric temperature is discussed. Author (revised)

Error probabilities are calculated for the detection of a target illuminated through a random medium in the presence of ambient noise. Comparisons are made between monostatic operation, in which double passage of the radiation leads to an enhanced amplitude and fluctuation of the received signal, and bistatic operation, where the outward and return radiation paths traverse uncorrelated regions of the intervening random medium. It is shown that although common transmit/receive optics are advantageous in the case of low signal to noise ratios, in normal regimes of operation a bistatic arrangement leads to lower total error probability, particularly when the scattering medium generates strong scintillation in the target plane. During the last four years, the Microwave Remote Sensing Laboratory of the University of Massachusetts has studied the polarimetric backscatter response of natural and man-made surfaces at 35, 95, and 225 GHz. These surfaces include grass, asphalt, snowcover, and trees. In addition, ground-based and airborne backscatter measurements of clouds and precipitation were made at 95 GHz. The results of these experiments are summarized by presenting histograms of normalized radar cross section for trees, snowcover, and clouds. The temporal dependence of the normalized radar cross section for snowcover is also presented for 95 and 225 GHz which shows a strong diurnal variation due to melting and refreezing. Also presented is the angular dependence of backscatter from grass and asphalt at 35, 95, and 225 GHz, as well as volume backscattering coefficients for airborne measurements of clouds and precipitation at 96 GHz. A HYBRID ELECTROMAGNETIC-STATISTICAL APPROACH FOR CHARACTERIZING MMW SCATTERING BY TERRAIN
FAWWAZ T. ULABY, PAUL SIQUEIRA, and KAMAL SARABANDI *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation 8 p (SEE N94-30495 08-32) Nov. 1993
(AGARD-CP-542) Copyright Avail: CASI HC A02/MF A03

The performance of millimeter wave (MMW) radar systems in target detection, navigation, and other applications depends in part on the scattering characteristics of the terrain background. Two different approaches have been pursued in the literature for characterizing MMW scattering by terrain. The first approach relies on the development of electromagnetic scattering models that relate the backscattering coefficient sigma of a given terrain type (such as bare ground surfaces, snow cover, and vegetation) to the physical properties of the terrain target, and then verifying model predictions though experimental observations conducted under semicontrolled field conditions. The second approach is entirely empirical in nature; it relies on the acquisition of extensive radar data from which statistical distributions are generated. This paper provides an overview of how the hybrid approach can be used to simulate the statistical properties of terrain backscatter at millimeter wavelengths for several types of terrain, including bare soil surfaces, vegetation, and snow cover. The hybrid approach incorporates scintillation effects associated with coherent sensors together with information about the mix of terrain categories present in the scene. Two types of input data (or a merged set of both) can be used as input to the clutter simulation package: measured data that is available in a University of Michigan data base or data generated by electromagnetic models. The data base is

available as a handbook that contains MMW scattering observations reported in the literature for certain terrain types and conditions. Alternatively, a set of electromagnetic models can be used for calculating the backscattering coefficient sigma of the specified terrain type. These models, which are semiempirical in form, are based on highly complicated theoretical models that had been tested against experimental observations. With this approach, it is possible to generate a probability density function for the backscatter from a certain type of terrain without the need for a measured clutter data base. This is particularly attractive at millimeter wavelengths because only a limited amount of terrain clutter data is currently available. Author

GRANULOMETRY IN ENVIRONMENTS WITH VERY SMALL PARTICLE CONCENTRATIONS [GRANULOMETRIE DE MILIEUX A FAIBLE CONCENTRATION DE PARTICULES]
A. DELFOUR, B. GUILLAME, and ALAIN P. JUNCHAT *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation 10 p (SEE N94-30495 08-32) Nov. 1993 In FRENCH
(AGARD-CP-542) Copyright Avail: CASI HC A02/MF A03

The principle of granulometry through particle light diffusion in environments with very low levels of concentration was studied. A model was built and its response, when particles were randomly distributed in the measured volume, was numerically simulated. Atmospheric, urban, rural, and seaside conditions were used in models with extended ranges of concentration. Several wavelengths of light were tested. Atmospheric aerosol granulometry is feasible if the concentration per volume is greater than or equal to 10(exp -5) ppm, and if the light wavelength is of the same order as the average size of the particles. The particles' contribution to atmospheric visibility may be measured if a preliminary calibration of the detection system is put into place. Laboratory equipment was used to validate the use of models. In order to simulate the appropriate particles' concentration, a 10 dm(exp 3) test chamber was built. Experiments, conducted with licopode powder (25 to 35 micron in diameter) in known concentration per volume, were correctly reproduced. Transl. by FLS

Radar cross section (RCS) measurements were made on an extensively instrumented ground-clutter patch over a period of one month from late summer to early fall. The instrumentation allowed collection of a full set of data on meteorological conditions, solar flux, and soil moisture content. The RCS measurements were made using a 95-GHz, polarimetric, monopulse instrumentation radar. The radar is all solid-state, coherent, frequency steppable over a 640-MHz bandwidth, and completely polarimetric for linearly or circularly polarized radiation. The clutter area measured was located in Grayling, Michigan, and consisted of a rectangular patch of ground, 50 by 100 m in area, at a range of about 100 to 250 m from the radar. The clutter patch included areas of bare sandy ground, short grass, low shrubs, evergreen trees, and deciduous trees and was similar to a NATO European environment. A wide range of atmospheric conditions were observed over the measurement period, including a few days of measurable snowfall. The paper describes analysis of the effects of different clutter types and different atmospheric conditions on the measured RCS of the clutter patch. Author (revised)

This paper reports piloted simulation results from the Integrated Control and Avionics for Air Superiority (ICAAS) piloted simulation evaluations. The program was to develop, integrate, and demonstrate critical technologies which will enable United States Air Force tactical fighter 'blue' aircraft to achieve superiority and survive when outnumbered by as much as four to one by enemy aircraft during air combat engagements. Primary emphasis was placed on beyond visual range (BVR) combat with provisions for effective transition to close-in combat. The ICAAS system was developed and tested in two stages. The first stage, called low risk ICAAS, was defined as employing aircraft and avionics technology with an initial operational date no later than 1995. The second stage, called medium risk ICAAS, was defined as employing aircraft and avionics technology with an initial operational date no later than 1998. Descriptions of the low risk and medium risk simulation configurations are given. Normalized (unclassified) results from both the low risk and medium risk ICAAS simulations are discussed. The results show the ICAAS system provided a significant improvement in air combat performance when compared to a current weapon system. Data are presented for both current generation and advanced fighter aircraft. The ICAAS technologies which are ready for flight testing in order to transition to the fighter fleet are described along with technologies needing additional development. Author (revised)

Since early 1991, the Electro-Optic Systems Department (EOSD) of GEC Marconi Avionics Ltd. (GMAv) has been collaborating closely with radar systems designers from GMAv's Radar System Division (RSD) to develop Multiple Target Track-While-Scan (MTTWS) algorithms for tracking applications involving the use of electro-optical sensors. This work has progressed to the stage where simulations of EO-adapted MTTWS systems are now available and are implemented in representative processing hardware. The paper gives a general 'top level' overview of the EO-adapted MTTWS design, including functional block diagrams and a description of each of its three key elements. Illustrative diagrams show the detection data path and the important decision-making processes involved in correctly identifying possible airborne targets from clutter and noise. Examples of the MTTWS simulation output are also given. This information is presented in the form of pseudo-IR imagery overlaid with the relevant track information to give an 'at-a-glance' view of system performance. A number of interesting examples effectively serve to demonstrate 'general' system performance, and superior system performance in non-standard/testing conditions. The paper hints at further extending performance in the integration of airborne radar and EO sensors, and discusses the related key issue of accurate inertial stabilization and referencing. Author

A modified Hough transform is proposed for multitarget track initiation. The proposed technique can initiate target tracks using data from as few as three scans. Simulated data as well as real radar plot data are used to test the initiator. Results show that its performance is superior to the conventional Hough transform in terms of false track rate without degradation in the probability of track detection. Author

The low-elevation tracking performance of naval fire-control radars may be degraded by specular multipath. Performance can be significantly improved provided the radar has sufficient frequency agility and the appropriate signal processing is used. This paper examines the performance of a number of alternative techniques: monopulse averaged over a group frequencies within the agile band, monopulse with averaging weighted according to the signal-to-noise ratio and the use of a detailed propagation model in a maximum likelihood estimation technique called the Refined Maximum Likelihood (RML) method. Simulation results are presented to show that moderate improvement can be obtained by using monopulse with frequency averaging with a better improvement given by weighted averaging, the degree of improvement increasing with agile bandwidth. Where very precise height tracking of targets in a specular multipath is required, the RML technique is best. While RML was originally developed for antenna array signal processing, it can be applied to the two sub antennas of a phase monopulse system provided a sufficient degree of frequency agility is available. In this latter application, the technique has been designated RMONO for Refined monopulse. The basis of the RML technique is presented followed by an evaluation of its performance using results obtained from two experimental trials. Author

CONTACT LEVEL FUSION OF RADAR AND IRST CONTACTS ON ALMOST ELECTROMAGNETICALLY SILENT PLATFORM
FRANCOIS BEGIN, MARC-ALAIN SIMARD, and PIERRE VALIN *In* AGARD, Pointing and Tracking Systems 9 p (SEE N94-36616 12-18) May 1994

The fusion of data coming from dissimilar sensors (passive/active) such as the IRST and radar raises the problem of the coordinate system used in the computation of the state vector. In single sensor tracking the IRST tracks are usually computed using an angle and angle rate coordinate system. In radar tracking, the state vector and the covariance matrix are generally computed in cartesian coordinates. Recent papers have shown the advantage of the modified spherical coordinates over cartesian coordinates in tracking passively AAW targets. It is thus natural to investigate if this advantage exists for fused sensors in an almost electromagnetically silent situation. Due to the missing range of the IRST, at the contact level fusion, the cartesian form of the 'purely' linear Kalman filter cannot be used directly without making non rigorous modifications. In this case, a linearized measurement matrix (H) can be used in a modified Kalman filter. This research pursues two goals: first, it analyzes the pertinence of the spherical and modified spherical coordinate formulation of the extended Kalman filter over the cartesian coordinate formulation and second, it evaluates the extent to which the platform can stay electromagnetically silent without damaging the quality of the tracking. The analysis shows the feasibility of data fusion in all three coordinate systems. The investigations are showing equivalent or better performances for the extended Kalman filter in cartesian coordinates. Sparse radar contacts are interleaved with regular IRST contacts, the former providing occasional range measurements to be fused with the regular more accurate angular information of the IRST. Electronic warfare (EW) has emerged as a critical driving force in modern warfare. New generations of weapon systems directly impact EW requirements and strategies. Modern combat aircraft are faced with a drastic change of a possible threat scenario consisting of a mix of Western and Eastern weapon systems. The deployment of advanced pulse doppler radar systems in A/A and G/A application augmented by extensive electro-optic capabilities, directed energy weapons (laser or particle beam), and electromagnetic/shockwave weapons requires a detailed reassessment of NATO EW processes. The complexity and diversity of future threat scenarios necessitate changes in NATO EW system concepts, and an update of existing equipment including modifications of tactics and combinations of EW resources to improve survivability. In recent years, powerful, flexible modelling tools for assessing and exploiting propagation conditions became available. Rapid advances in mini and microcomputer technology have put complex models with sophisticated user interfaces at the disposal of non-specialists. These range from system design tools to near real-time operational and tactical decision aids that include models and databases of necessary environmental parameters. Prediction tools are required for communications, radar, and navigation applications, and cover the frequency spectrum from extremely low frequency (ELF) to optical. These lectures concentrate on the prediction tools, but also cover the background required to understand the models. Topics include the ionosphere, ground wave propagation, terrain diffraction, refractive effects, hydrometers, atmopsheric gases, electro-optics, and remote sensing. For individual titles, see N95-14826 through N95-14835.

The use of ionospheric models and ray tracing models as components of a propagation model are discussed. These can be used as decision aids to support human interpretation of ionospheric propagation. The physical basis for ionospheric decision aids is introduced by reference to ionospheric morphology and the basic theory of ionospheric propagation, which, along with ray tracing techniques, is then reviewed. This lecture on ground wave and diffraction deals with the attenuation of a radio signal resulting from its interaction with the ground, and in some cases, with its interaction with objects on the ground. At lower frequencies, the electrical characteristics of the ground are very important, and the height variations less so, while at higher frequencies, the opposite is true. At lower frequencies the wave is usually vertically polarized, since antennas are close to the ground in terms of wavelength and a horizontally polarized wave tends to be shorted out by the conductivity of the earth. At the higher frequencies, both polarizations are used, and at the highest frequencies, it makes little difference which is used. Derived from text

Sensing of radio refractivity has historically been accomplished with direct sensing techniques such as radiosondes. While direct sensing techniques provide good data for propagation assessment purposes, remotely sensed data would be more desirable. Various direct and remote sensing techniques and an assessment of their potential operational usefulness are reviewed. Included are radiosondes, refractometers, radar sounders, lidars, satellite-based sensors, radiometric and radio propagation techniques. The need for and feasibility of providing three-dimensional, time-varying refractivity fields for propagation assessment are addressed. Aerosol extinction is often the atmospheric parameter limiting electrooptical systems performance. For proper performance assessment, slant path extinction must be known. For several decades, attempts have been made to infer aerosol extinction from lidar backscatter measurements. A discussion of selected lidar techniques and their limitations is presented. Author

Radio wave propagation in the very high frequency (VHF) to extremely high frequency (EHF) bands at low elevation angles and near the earth's surface is almost always affected by refraction. This lecture details these effects and the various methods used to model them, from simple effective-earth-radius factors for standard refraction to parabolic-equation methods for range-dependent ducting environments. Refraction and Snell's law are discussed and standard and nonstandard propagation mechanisms are defined. To establish the significance of nonstandard propagation effects, some statistics on the occurrence of ducting around the world are presented. Author (revised)

The basic propagation theory is presented in a form usable for electro-optical systems engineers. Starting with the different contributions which affect an electro-optical system under environmental conditions (background, target-signature, atmospheric propagation, sensor specifications, signal-processing) the atmospheric transmittance separated into molecular and particle contributions is discussed. Both absorption and scattering terms as well as scattering functions are given with respect to their wavelength dependence. For statistical system performance analysis extinction coefficients for Nd:YAG and CO2 laser radiation derived from measured OPAQUE data of Southern Germany are discussed. They are given as a function of the month of the year for specific cumulative probabilities. Optical turbulence which is affecting laser systems more than broad band systems is discussed with emphasis on intensity and phase fluctuation in the atmospheric boundary layer. Nonlinear effects encountered in high-energy laser beam propagation through the atmosphere are illustrated. Author

The presence of rain on a propagation path can cause severe attenuation in the super high frequency (SHF) and extremely high frequency (EHF) frequency bands, reducing the performance of communications and radar systems. Rain, snow and ice can also give rise to scatter, causing radar clutter and the potential for interference to, and an increased probability of intercept of communications links. The structure of precipitation and cloud is discussed, and an overview of the physics of scatter of electromagnetic waves by rain is given. This is followed by a description of practical, statistical methods for the prediction of rain attenuation on terrestrial, radar and satcom systems, and simple cross section models for radar clutter and bistatic scatter. Atmospheric gases absorb energy from electromagnetic waves because of molecular resonances at particular frequencies in the SHF and EHF bands. The mechanisms are discussed and practical prediction procedures for the calculation of gaseous attenuation given.

The requirement for highly survivable communications (HSC) for essential command functions in military operations does not need any justification. The ability to communicate under extreme jamming levels and adverse propagation conditions, including high altitude nuclear events, is a very important requirement. There are also many natural disaster related requirements that also need such highly survivable communications. The prevalent and in a sense classical, approach to provide highly assured connectivity can be summarized as follows: Take a particular propagation medium and try to obtain the ultimate performance from it. There are many examples of this philosophy some successful, most not. Our approach, on the other hand, is to use complementary multi-media or mixed-media where communication links utilizing essentially commercial-off-the-shelf (COTS) equipment are integrated using packet radio (PR) techniques. There is also, in our view, an even more fundamental, recently discovered consideration why the expectation of continuous incremental refinement of a system using a given single media may be be achievable. This is derived from the theory of 'deterministic uncertainty' or more popularly known as 'theory of CHAOS', systems whose state space behavior has fractal characteristics. We will elaborate on this novel argument. Complementary multi-media approach has been the focus for all HSC communications activities at STC since 1982. The original STC studies and prototypes were in response to requirements of broadcasting (i.e., one-way transmission) information. A high frequency (HF)/meteorburst (MB) system was developed/prototyped/tested demonstrating the cost effectiveness of the approach. These results are reviewed. More recently, in 1992 STC has completed the development/test of an Open Systems Interconnection (OSI) HF packet radio protocol as no such open or non-proprietary protocol exists. This protocol has been fully tested, documented and made available to all NATO nations/industries. These extensive results show that significant improvements in throughput of up to many times are obtained. A similar development for an OSI MB protocol has also been completed and combined with the HF protocol to obtain an OSI HF/MB link layer protocol with unique properties for HSC networks. Description of these protocols and the relevant results are presented. The conclusion is that, HSC networks using standard COTS transceivers/modems with OSI PRO protocols can provide highly survivable connectivity, by providing the most important ingredient of survivability, media diversity.

QOS DRIVEN ROUTING IN PACKET SWITCHED NETWORKS OF MULTIPLE TRANSMISSION MEDIA
C. TAMVACLIS *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 9 p (SEE N95-20921 06-32) Jul. 1994
(AGARD-CP-543) Copyright Avail: CASI HC A02/MF A04

This paper discusses the application of Quality of Service (QoS) driven routing on packet-swtiched, heterogeneous networks. It is assumed that the network makes use of multiple transmission media of different types including narrowband radio based media such as those used in military tactical and emergency networks, e.g. ECCM SATCOM, HF radio, etc. A critical problem in the operation of such networks is the volatile performance of the transmission media, compounded by the fact that each transmission medium may respond differently to stress conditions. QoS driven routing provides an effective way to handle transmission media

performance fluctuations and optimizing the use of all the available communication resources. QoS driven routing means that packet routes are selected according to a global optimization criterion that takes into account not only network connectivity, but also the application QoS requirements, and the currently available QoS from the network links. A routing architecture is described for implementing QoS driven routing on a connectionless internetwork of multiple transmission media. This architecture is based on the use of civilian networking standards and it is implementable using commercial off-the-shelf equipment. Author

Modelling codes exist for many of the propagation mechanisms which may prevail in the frequency range of approximately 2 to 200MHz and many of the models are embodied in CCIR recommendations. Within the past few years, a number of simulation codes have been developed for use within various projects carried out by the Hull-Lancaster Communications Research Group (HLCRG). The proposed paper will describe current work aimed at bringing together the various models and simulation codes in order to produce a realistic simulation of the multiple mechanism propagation path. The multiple mechanisms under consideration conventionally include groundware, ionospheric skywave, sporadic E, ducting and the various scatter modes. In addition, recent work carried out by the HLCRG has revealed that tropospheric reflection may be responsible for stable propagation which is usable in the frequency range 30 to 70MHz for short (up to 400km) over the horizon paths. The development of a propagation model for this mechanism will be included in the presentation. Author

In automatic repeat request (ARQ) systems, i.e. those that depend on feedback from the receiver as to the state of the received message, relatively low 'overhead' check digits are required for reliable error detection. A properly designed system of this type can be very reliable, but under poor channel conditions the number of repetitions become excessive. Forward error correction techniques that can correct a mixture of burst and random errors are most suitable for predictable real channels. Recently, an adaptive coding technique has been introduced. The main purpose of an adaptive coding scheme is to permit only the necessary degree of error correction to be applied to the transmitted information according to the channel conditions. The concatenated codes, first introduced by Forney, are formed by cascading two encoders, an inner and outer, where the first is usually a linear binary code, or a combination of two linear binary codes, and the outer is usually a multi-level Reed-Solomon (RS) code over GF(2 exp m). It is known, that with choice of inner and outer codes, concatenated codes become very powerful codes for random and burst error correction. The objective of the proposed paper is to investigate adaptive concatenated codes, which can provide a more efficient error protection in channels with different types of errors. Derived from text

A recently completed study of passive sensing techniques for hf communication systems has shown that these sensing techniques can yield data which may be of use in the control of adaptive hf communication systems. The aim of this paper is to review work carried out to date on these techniques and to examine the feasibility of applying similar techniques to radio systems utilizing higher carrier frequencies, up to around 200MHz, where many propagation modes other than ionospheric skywave may exist. Whilst inputs for the control of adaptive radio systems may be derived from a number of sources, many techniques, such as pilot-tone soundings and the transmission of training sequences, involve radiation of signals which may be undesirable in a tactical situation. System control information may also be derived by monitoring other signals which are already present in related parts of the radio spectrum, allowing more covert operation and avoiding unnecessary pollution of the radio spectrum. Derivation of such control information for use in hf systems has been studied in some detail, utilizing the following types of radio signals existing in the hf band: swept frequency sounder signals radiated by other uses of the hf spectrum, broadcast signals, standard time signals, meteorological data signals (RTTY), and overall statistical occupancy measurements of the spectrum. Some of these techniques would also be applicable to the multimechanism case, provided that the more complex propagation inversion, which is due to the greater range of propagation mechanisms available, can be taken into account. Additional, higher frequency, sources of RF energy which may provide data through passive monitoring, include aeronautical navigation beacons, amateur beacons and various types of radar signals. Use may also be made of low-orbiting satellite signals, although these present tracking problems in terms of doppler shift and give data mainly related to ionospheric scintillation and hence magnetic storm effects. We have analyzed the duty cycle from a very high frequency polar cap path in Greenland. We find that at 35 MHz and 45 MHz the path is often sustained by sporadic E layers rather than by meteor scatter. At the higher frequencies of 65 MHz and 85 MHz we find that the path is generally dominated by meteor scatter modes. The diurnal, seasonal and geomagnetic variations of sporadic E are examined and off line decision aid models are provided to evaluate the magnitude of multiple mechanism propagation on the path. This paper deals with some experimental results. These correspond to radio links operating in the low VHF band (30 - 80 MHz) and in the range 300 - 500 km. For those distances and frequencies, the received signal is affected by fast and slow variations. On the one hand, time-frequency analysis (wavelength transform) shows that the mainly dominant propagation mode is due to partial reflection on random surfaces (sheets). At a given time, only three or four reflections are significant and contribute to the received power. On the other hand, statistics of slow variations are examined and a log-normal distribution is observed. These slow variations are correlated with meteorological data (radiosonde). Best correlations are obtained with atmospheric pressure, refractive index and height of the tropopause. Author

PROBLEMS OF CODING IN MULTIPATH CHANNELS [LES PROBLEMES DE CODAGE DANS LES CANAUX A TRAJETS MULTIPLES]

C. GOUTELARD *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 9 p (SEE N95-20921 06-32) Jul. 1994 In FRENCH

Transmission channels are essentially multipaths. Multipaths are introduced by birefringences of the medium as in the ionosphere, by inhomogeneity as in the ionosphere and troposphere, or by reflections on obstacles as in urban or tropospheric links. The multipaths create phenomena of interference which introduce modifications of amplitude and phase of the transfer function of the channel. The stationarity of the channels complicates their use, in particular in numerical telecommunications or in teledetection. Countermeasures for fading problems call upon particular techniques of modulation or coding devices. The choice, a priori, of a modulation to carry out a system of telecommunication often involves a complexity of coding necessary to correct the errors introduced by the channel. A general method for the analysis of the channels and choice of the modulation and coding is proposed in this presentation. It is shown that the optimum choice cannot be done without an analysis of the distribution of the errors which depends on the transfer function of the channel, but also on the noise and the interferences. From the knowledge of the transfer function, interferences and noise, it is shown that a general method can be created resulting in a model of error distribution that can support code selection. The codes to be used are often very complex. The technique of interlacing can be used to avoid packages of errors, however quasi interval fadings which appear in the channels with multipaths often make regular interlacing ineffective and it then becomes necessary to consider random or pseudo-random interlacing.

The split-step parabolic equation (SSPE) has been used extensively to model tropospheric propagation over the sea, but recent efforts have extended this method to propagation over arbitrary terrain. At the Naval Command, Control and Ocean Surveillance Center (NCCOSC), Research, Development, Test and Evaluation Division, a split-step Terrain Parabolic Equation Model (TPEM) has been developed that takes into account variable terrain and range-dependent refractivity profiles. While TPEM has been previously shown to compare favorably with measured data and other existing terrain models, two alternative methods to model radiowave propagation over terrain, implemented within TPEM, will be presented that give a two to ten-fold decrease in execution time. These two methods are also shown to agree well with measured data. Author

The propagation of radio waves in the atmosphere is determined by the index of refraction which is sensitive to the pressure, temperature and moisture of the air. In the vicinity of the surface of the sea, there is a strong gradient of moisture related to the evaporation of water; it gives rise to a fast decrease of the index of the air creating a conduit of propagation in vicinity of surface. A source located in the interior of the conduit (i.e., at an altitude ranging between that of the minimum of the modified index and sea surface) sees most of its energy remaining captive inside this conduit. This has as an operational consequence - a considerable increase in the range of the radio hardware working in the vicinity of the surface of the sea. In addition, the propagation inside the conduit is characterized by the presence of multipaths related to the successive reflection of the .electromagnetic wave on the surface of the sea and the boundary of the conduit. What results is a series of reinforcements and attenuations of the field being propagated in the conduit. Taking into account the practical importance of these effects it is advisable to have suitable methods of evaluation. In this talk three methods are examined: (1) parabolic equation method, (2) method of modes, and (3) method of geometrical optics. The parabolic equation method consists of making an approximation of the wave equation by supposing that the field is propagated around a primary direction. Under these conditions one reduces the equation of propagation to a partial derivative equation of parabolic type which leads to an easy algorithm to work with. The method of modes makes it possible to carry out calculations in an entirely analytical way by supposing that the profile of the index follows a simple law. This method constitutes an analytical reference with respect to the two other methods which are numerical. The method of geometric optics is an asymptotic method. It consists of considering the trajectory of the rays resulting from the source by solving the eikonal equation. The intensity of the electromagnetic field can be given in conjunction with the equation of the trajectories; the calculation of the divergence of the wave vector tangent to the ray passing by the point where the field is evaluated. One thus obtains a system of ordinary differential equations which can be solved numerically by the method of Runge-Kutta. Each one of these methods is analyzed and a comparison between them is carried out on a number of concrete examples. In each case the theoretical limits, the advantages, and the limits of use of the three methods are highlighted. Transl. by CASI

Telecommunication between a fixed basic station and a vehicle moving on the surface of the ground are subjected to multiple

reflections. When the frequency of the carrier is of the order or higher than 1 GHz, the majority of the obstacles located between the emitter and the receiver has dimensions much larger than the wavelength and a predictive model of the conditions of propagation can be based on the theory of rays and in particular on the uniform theory of diffraction (UTD). The first part of this article presents a brief review of the mathematical formalism and the way of introducing the complex permittivity of the ground into the ideal models. In the case of propagation in an urban environment, a comparison between the results obtained using the UTD and those based on approximate models which account for multiple diffractions is carried out. An important geometrical configuration for which the multiple reflections play a very important part relates to the propagations in tunnels. The analysis is undertaken by successively considering the intrinsic propagation in the tunnel, i.e. by supposing that the tunnel is infinitely long, then the free-tunnel transition space. The study is carried out in the frequency domain then temporal domain closely connected to highlight the fluctuations of amplitude of the signal and the delays to the multipaths. The theoretical predictions are then compared with the experimental results. Transl. by CASI

Multipath, jamming, listening and detection are the main limitations for mobile radio communications. Spread spectrum techniques, especially frequency hopping, can be used to avoid these problems. Therefore, a wideband simulation for multipath mobile channels appeared the most appropriate evaluation technique. It also gives useful indications for system characteristic improvements. This paper presents the design and realization of a new UHF-VHF propagation simulator, which can be considered as an extended version of Bussgang's one. This frequency hopping simulator (up to 100,000 hops per second) is wideband thus capable to deal with spread spectrum signals. As it generates up to 16 paths, it can be used in almost all mobile radio propagation situations. Moreover, it is also able to simulate high mobile relative speeds up to 2000km/h such as air-air communication systems. This simulator can reproduce, in laboratory, 16 rays Rician or Rayleigh fading channels with a maximum time delay of about 15 ms. At the highest frequency of 1200 MHz, Doppler rates up to 2 kHz can be generated corresponding to vehicle speeds up to 2000 km/h. Let note that the Bussgang simulator was defined for narrowband and fixed radio communications. In both equipments, in-phase and quadrature signals are obtained using two numerical transversal filters. Simulation results were derived in various situations especially in terrestrial urban and suburban environments, where they could be compared with measurements. The main advantage of the simulator lies in its capacity to simulate the high speed and wideband mobile radio communication channels. Author

Radiowave propagation on mixed land/sea paths is affected by both atmospheric refraction and terrain effects. The parabolic equation method provides a numerical solution for calculation of field-strength in these circumstances. We give a few applications of the finite-difference PE method, which is particularly well-adapted to problems where ground effects are important. A case in point is that of detection of low targets above a rough sea surface. For air-defense applications, PE computing requirements are prohibitive. We describe a novel method, the horizontal PE method, which allows fast computation of signal strength in large domains, and apply it to calculations of radar coverage. Author

MODELING TROPOSPHERIC DUCTING EFFECTS ON SATELLITE-TO-GROUND PATHS

HERBERT V. HITNEY *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 5 p (SEE N95-20921 06-32) Jul. 1994

(AGARD-CP-543) Copyright Avail: CASI HC A01/MF A04

Satellite-to-ground propagation paths are frequently affected by tropospheric refraction and ducting at very low elevation angles. Common effects are substantial enhancements of signals at ranges that would normally be beyond the horizon, and severe distortions of the patterns created by the coherent interferences of multiple propagation paths, in particular the direct and sea-reflected signals. Traditional methods to model tropospheric ducting effects, such as waveguide or parabolic equation methods, are difficult to apply to typical satellite heights. This paper will describe a parabolic-equation and ray-optics hybrid method to model these sometimes important effects, and compare modelled and measured results using a 1000-km high satellite transmitting at 1239 and 2891 MHz. Modeling of electromagnetic propagation in the troposphere has been advanced in the last decade to the point where both the vertical and horizontal variation of refractivity can be accommodated readily. In particular, parabolic equation models inherently allow for lateral and vertical inhomogeneities. A hybrid ray-optics/parabolic equation model is utilized to predict propagation loss for a range-varying refractive structure to demonstrate the model obeys the Sommerfeld-Pfrang statement of the Lorentz Reciprocity Theorem. For a radar system in a maritime environment, the probability of detection of a target at a low altitude is strongly dependent on the conditions of the atmosphere and the sea surface. In order to determine the detection probability of a target at low altitude, these conditions should be taken into account. This paper presents numerical methods to calculate electromagnetic propagation in an evaporation duct and to calculate sea clutter returns. Author

By inducing scintillation of the transmitted signals, atmospheric turbulence affect both satellite and line-of-sight communication systems in the millimeter-waves range. After a characterization of the scintillation effect from theory and experiments, this paper presents two deterministic models developed at the Microwaves Laboratory U.C.L. for the simulation of scintillation. The first model accounts for the physical process of cloud induced turbulence

that yields scintillation on satellite links and the second one deals with the turbulence in the lower atmospheric layer that affects terrestrial paths. These models allow to retrieve the turbulent configuration that produce scintillation, to simulate the scintillation effects on various links and finally to predict the impact of scintillation on the performances of communication systems. Experimental results of radio propagation measurements at 853 MHz are given for a 500 km troposcatter link in the Canadian High Arctic. The experimental data were acquired using a narrow band measurement system that was developed to permit a transmitting power of only 100 Watts while using a 4.5 meter dish at each end of the link. The system includes a digital signal processor (DSP) receiver for signal strength computation and a high stability noise source reference for amplitude calibration. The main characteristics of this system are described in this paper. Detailed fading distributions are presented for examples of slow and fast fading periods and compared with Rayleigh distributions. An estimate of the long term median path loss is made and compared with values predicted using accepted techniques. The results are believed to be the first ever presented for a microwave troposcatter link above the 80th parallel. Author

LARGE BISTATIC ANGLE CLUTTER DEPOLARIZATION STUDY

D. J. MCLAUGHLIN, E. BOLTNIEW, J. BARCLAY, R. S. RAGHAVAN, and M. J. SOWA (Rome Lab., Hanscom AFB, MA.) *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 10 p (SEE N95-20921 06-32) Jul. 1994

(AGARD-CP-543) Copyright Avail: CASI HC A02/MF A04

A bistatic radar test bed has recently been developed to measure the depolarization behavior of clutter at large bistatic angles in Eastern Massachusetts. Results presented in this paper describe the co- and cross-polarized S-Band NRCS for low resolution (300m by 300m) forested clutter cells viewed at low grazing angles. We also describe the variation in mean scattered power versus linear receiver antenna orientation angle for both vertical and horizontal transmitted polarizations. Measurements of a 20 km by 20 km region of rolling hills show that vertical copolarized NRCS exceeds horizontal copolarized NRCS by an average of 8 dB over a range of bistatic angles from 100 degrees to 160 degrees. The average polarization ratio is minus 12 dB for vertical transmitter polarization and minus 5 dB for horizontal transmitter polarization. For both transmitter polarizations and variable linear receiver antenna polarization, maximum scatter power was observed when transmitter and receiver antennas were copolarized while minimum received power was observed when the antennas were crosspolarized. Power fluctuation statistical distributions are approximately exponential for all linear receiver antenna polarization angles. Author

In this paper, ray-tracing simulation is used to model the dynamic behavior of the propagation channel in presence of a single super-refractive layer. Three typical mechanisms of layer formation and evolution are simulated according to experimental observations. (1) A ground-based layer formed by nocturnal cooling of the Earth's surface, its intensity increasing with time, (2) an elevating layer, that is a ground-based layer which weakens in rising, its intensity decreasing linearly with height, and (3) an elevated layer formed when a warm dry air mass is produced in the upper atmosphere; this layer grows with time. For each of these three types of layer, a ray-tracing program is used to compute the variations with time of the ray parameters and of the received signal level. As the statistics of the speed of layer formation and evolution are not precisely known, the time scale used in this study is somewhat arbitrary. However, this technique allows one to identify three typical fading patterns and to help interpret the physical mechanisms involved in the generation of multipath propagation. The frequency selective nature of the propagation channel bandwidth is then investigated over a 10.7-11.7 GHz in looking for the influence of each type of layer on the transfer function. Some experimental evidence relating to, and confirming, the predicted behavior values is also considered. Author

This paper describes the features of measurement equipment developed to measure impulse response estimates of mobile radio channels in less than a ms per measurement. The development of such equipment was required to measure mobile radio channels in realistic operating scenarios, in a normal sized vehicle moving at typical speeds in different environments. Up to speeds of 70 km/hr, the measurement period is short enough to assume the equipment is measuring the same channel during the whole sampling interval. AT the transmitter end of the measurement system, a wideband signal (10 MHz) is produced by modulating a carrier frequency with a 511 bit pseudo random sequence at 5 Mb/s and transmitted through the radio channel. The received signal is down-converted to 70 MHz and demodulated by a complex demodulator. The quadrature baseband signals at the demodulator outputs are then filtered and sampled at high speed by two fast digitizers. During this process, the data are stored in large memory banks to allow a fast sampling rate during a long period of time. Data are transferred to laser disks for further processing in the laboratory. Impulse response of radio channels are estimated by performing a software correlation between a measurement system back to back reference and real time measurements. A minivan was modified to hold the receiver, digitizers, memory banks and the computer. A shaft encoder was attached to its rear left wheel to trigger measurements while moving. Features of the system are discussed along with the effects of data block length, signal to noise ratio, sampling rate, memory size and phase stability on the design of the measurement equipment. Finally, some measurement results are presented and discussed. Author

LINE-OF-SIGHT MULTIPATH PROPAGATION MEASUREMENTS AT 15 GHZ OVER 500 MHZ BANDWIDTH

M. TOUATI, G. ELZEIN, and J. CITERNE *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 10 p (SEE N95-20921 06-32) Jul. 1994

(AGARD-CP-543) Copyright Avail: CASI HC A02/MF A04

An experimental wideband grazing radio link at 15 GHz has been set up on a 17.6 Km line-of-sight between Laille and Rennes to measure the variations of the propagation medium characteristics (attenuation and group delay versus frequency) due to meteorological effects. For this, a meteorological system was set up at the receiver station in order to measure the variations of the meteorological parameters (temperatures, pressure, rain precipitation, speed and direction of the wind). Consequently, the atmosphere refractive index is obtained. A particular interest is given to the occurrence of multipath fading in clear air caused by low-level layering in the troposphere. The collecting and recording of the propagation data (attenuation and group delay), from the MLA (microwave Link Analyzer), and that which relates to the meteorological characteristics, from the meteorological station, are executed using a computer program in a sequential manner. The channel impulse response, corresponding to each measured data, is calculated to deduce the number of rays detected and their different delays respectively. Besides this and using the meteorological parameters data acquired, the refractivity gradient is calculated in order to correlate the multipath fading occurrence to the meteorological parameters. EXPERIMENTAL STUDY OF THE HELICOPTER-MOBILE RADIOELECTRICAL CHANNEL AND POSSIBLE EXTENSION TO THE SATELLITE-MOBILE CHANNEL

V. BLANCHETIERE-CIARLETTI, M. SYLVAIN, and P. LEMENN *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 12 p (SEE N95-20921 06-32) Jul. 1994

(AGARD-CP-543) Copyright Avail: CASI HC A03/MF A04

The use of satellite seems to be an answer to the radioelectrical covering problem for the mobile communications, particularly in the low populated areas. Frequency bands at 1.5 and 2.5 GHz have been dedicated to these future services. Satellite-mobile links will be much more affected by propagation phenomena than the existing links between satellites and fixed stations. The reasons for that are twofold: The probable use of LEO (Low-Earth-Orbit) satellites instead of GEO; such satellites will have to be received at relatively low elevation to limit their number; the use of mobile communication terminals with small and non directive antennas that must work in various environments instead of terrestrian stations located at carefully chosen places and equipped with large diameter paraboloids. These propagation phenomena mainly consist in the fading of the signal level (shadowing of the link), and a frequency selective fading due to multipath propagation. The experience run by C.R.P.E. is aimed at a better understanding of the satellite-mobile propagation channel at fixed frequency as well as on a large band. In this paper, we discuss preliminary results from a series of propagation measurements performed (by lack of any experimental satellite) on an experimental radio link at 1.45 GHz on a of 20 MHz bandwidth between a helicopter flying at a height of 2 km and a mobile receiver. The whole experiment has been run in a rural environment in Brittany (France). In a first part, we illustrate the quality of the data collected during the experiment on a typical case study and give a possible physical interpretation of the observed phenomena. Then we present statistical results concerning the various characteristics (attenuation and delay spreads) of the propagation channel. Finally, we discuss the problem of using a helicopter (flying at a height of 2 km) as a substitute for a satellite at about 1000 km and try to estimate to what extent it is possible to use the data collected during this experiment to characterize the satellite-mobile channel. To do that, both the helicopter-mobile and the satellite-mobile propagation channels are simulated under the same environmental conditions. Author

COMPARATIVE STUDY OF C- AND K-BAND PROPAGATION MECHANISMS BEYOND THE HORIZON

UVE H. W. LAMMERS, RICHARD A. MARR, ROBERT K. CRANE (Oklahoma Univ., Norman, OK.), and MAGNUS WENNEMYR (Oklahoma Univ., Norman, OK.) *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 7 p (SEE N95-20921 06-32) Jul. 1994

(AGARD-CP-543) Copyright Avail: CASI HC A02/MF A04

At intervals over a period of several years, we conducted simultaneous troposcatter measurements at frequencies of 4.95 and 15.73 GHz on a 161 km path in the northeastern United States. This ensured a fair comparison within a largely unspecified but identical propagation medium. Besides signal level, both systems yielded Doppler information on the propagation mechanism. In addition, the Ku-band system provided delay resolution by pseudorandom phase modulation. On the basis of these data, three primary propagation mechanisms could be identified: clear air turbulent scatter, rain scatter, and ducting. Criteria are given for the identification of these mechanisms along with the resulting received signal level and delay spread distributions under each propagation condition. Author

ANGLE DIVERSITY ON DIGITAL MICROWAVE LINKS: ANTENNA DESIGN AND EXPERIMENTAL RESULTS

D. BEAUFORT and L. P. LIGHART (Technische Hogeschool, Delft, Netherlands.) *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 7 p (SEE N95-20921 06-32) Jul. 1994

(AGARD-CP-543) Copyright Avail: CASI HC A02/MF A04

PTT Research and Delft University of Technology examined the merits of angle diversity for multipath fading reduction on digital microwave links. A dual-polarized hybrid reflector array, suitable for beam switching in the vertical plane, was designed and produced. The antenna specifications were based on extensive propagation studies. The antenna was tested for two years on a 45 km hop in The Netherlands. It was found that switching between the antenna beams is superior to adaptive (maximum power) combining. Switching reduces the time that the Bit Error Ratio (BER) exceeds 10(exp -3) by a factor 27. Author

MITIGATION OF EFFECTS OF MULTIPLE PATH NULLS AT SUPER-HIGH FREQUENCIES THROUGH DIVERSITY AND NETWORKING

N. DAVE *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 12 p (SEE N95-20921 06-32) Jul. 1994

(AGARD-CP-543) Copyright Avail: CASI HC A03/MF A04

The goal of this work is to investigate the design issues implied by multipath effects for a high bandwidth communication network consisting of platforms in a Navy battle group. This communication network is designed to operate using super-high frequency (SHF) or ultra-high frequency (UHF) line-of-sight (LOS) propagation, and must be robust to variations in link quality due to platform motion or deletion, as well as to the effects of multipath propagation. High bandwidth in this context implies data rate in excess of 1.544 megabits per second (Mbps), known as 'TI' in the commercial world. Multipath nulls at the above frequencies can render links useless at certain ranges. In this work, we briefly discuss the well-known methods of height and frequency diversity, as well as a less frequently used but potentially powerful method of 'path diversity' through networking, to alleviate the ill effects of multipath nulls. The communication system configurations discussed are appropriate for expected platform separations in post-Cold War battle group scenarios, which envision most platforms within line-of-sight (LOS) distance from each other, i.e., separated by no more than about 20 nautical miles (nmi).

MULTIPATH IMPACT ON GROUND-BASED GLOBAL POSITIONING SYSTEM RANGE MEASUREMENTS: ASPECTS OF MEASUREMENT, MODELING, AND MITIGATION

G. J. BISHOP and E. A. HOLLAND (Northwest Research Associates, Inc., Bellevue, WA.) *In* AGARD, Multiple Mechanism Propagation Paths (MMPPs): Their Characterisation and Influence on System Design 10 p (SEE N95-20921 06-32) Jul. 1994
(AGARD-CP-543) Copyright Avail: CASI HC A02/MF A04

Multiple mechanisms propagation paths (multipath) can be the most important error source in ground-based Global Positioning System (GPS) measurement of range to the satellites. This multipath error, arising from a combination of the direct path and reflections from objects relatively close to the receiving antenna, can at times exceed the ionospheric delay error, which the two-frequency (1228 and 1575 MHz) GPS signal format is designed to measure and correct. GPS multipath can seriously degrade Differential GPS (DGPS) navigation, geodetic measurements, ionospheric monitoring, and other GPS applications, yet the source of the problem may not be evident without the use of specialized tests. Several techniques have been proposed to reduce the effects of GPS multipath; these include: improved receiver technology, specialized antenna designs, and various modeling or filtering approaches. This paper illustrates the nature of the two-frequency GPS multipath problem with measurement data from typical ground-based installations, exhibiting variation in multipath conditions, ranging from low to quite high for the varying geometries of the available satellite tracks. Leading mitigation techniques are reviewed, with emphasis on multipath modeling. A new simple modeling approach currently being studied by Phillips Laboratory is discussed. This technique takes advantage of the daily repetition of the GPS observation geometry from a ground station to create a 'multipath template' specific to each satellite pass, and reduce multipath effects on successive days. Data is presented showing significant improvement in a severe multipath environment and contrasting the effectiveness of this approach with all-sky modeling techniques. Mitigation techniques for GPS multipath show potential to enable GPS ground-based range and ionospheric measurement to greatly reduce errors at low elevation angles, leading to improved accuracy and wider coverage area capability. Propagation mechanisms have a detrimental effect on the accuracy of satellite positioning systems such as GPS and GLONASS. The ionosphere at times of high activity will cause the greatest error due to the propagation medium. This paper describes a dual GPS/GLONASS receiver that is capable of measuring the ionospheric delay in the measured GLONASS pseudo ranges using both the code and carrier phases. This allows the pseudo ranges to be corrected for ionospheric delay and a more accurate position solution to be calculated. This paper describes the receiver architecture and fundamental accuracy; receiver measurement noise and calibration are also discussed before the impact of propagation mechanisms on the measurements are investigated. The measurement of the line of sight ionospheric delay, from a GLONASS satellite, is shown and compared with the GPS transmitted ionospheric model. An example of GLONASS P code navigation is given with and without correction for the ionosphere. Author

In recent military operations trans-ionospheric satellite to ground communications have been utilized in the equatorial region. One problem for the predominantly 250 MHz systems has been fading due to irregularities in the region within plus and minus 20 degrees of the magnetic equator. A similar problem has been encountered at high latitudes. For minimizing the effect of the fading, one might expect that radio links sufficiently separated in frequency and polarization would be effective in combating scintillation. Unfortunately frequency separations would have to be of the order of 100 MHz to obtain an adequate diversity improvement. The use of right and left circular polarization or of orthogonal linear polarizations is not effective. However, time diversity is a demonstrated procedure for overcoming scintillation but there is a loss of using coding or redundancy and a reluctance to complicate the system with modems. If the paths from a single satellite are sufficiently well separated then fading on two links is uncorrelated and diversity gain may be achieved. Unfortunately at equatorial latitudes separations of the order of a kilometer are involved. Another use of 'space diversity' can be effective. If the paths from two satellites with spacing between them are available and there is recognition that scintillation is causing the fading on the path to one satellite, then operators can utilize the path to a second satellite. For equatorial paths the operator must be alert as to the time development of irregularities and the dynamics of plume development. The differences in activity on the paths are due to two aspects of the irregularity plume i.e. the start time as the sunset moves westward and the spacing between plumes on the very active days. Examples of the time difference between the start of equatorial scintillations on one path versus that of another have been recorded in many sectors of the world. The results of these studies as applied to the problem of multiple paths will be shown. At high latitudes during moderate magnetic activity, it is possible to find paths that are not dominated by irregularities. However at auroral latitudes when a magnetic storm commences, the irregularity development moves equatorward with great rapidity and encompasses large areas. It is then difficult to find a path free of irregularities. Author

The general theory describing reflection of electro-magnetic waves from irregular reflectors was formulated by using path integral techniques. The general formulae reproduce the well known reflection coefficients for wave scattering from random rough surfaces derived by using Kirchhoff's theory or perturbation theory. The theory was used to determine the degradation of an OTH radar signal scattered from irregular Artificial Ionospheric Mirrors (AIM). The cases of density irregularities induced by fluctuations in the ambient neutral density and by fluctuations in the heater power were separately examined. Scaling laws and bounds for minimal signal loss were derived. Author

Analysis of approximately one year's data from an operational OTH radar shows that equatorial clutter, originating in the ionosphere in regions up to 14,000 km from the radar, directly impacts the radar's performance. The radio wave propagation to these regions often involves from three or more ground hops depending on the radar's azimuth. These phenomena are important to all OTH radar systems in that great circle paths always cross the magnetic equator. The special data processing developed for this program uses both the long range (to 8000 nm) wideband 6 to 28 MHz) backscatter ionograms made routinely at selected azimuths and the radar's amplitude, range and Doppler data format, measuring the frequency of occurence, location and intensity of the clutter as a function of time and azimuth. These data indicate that intense ionospheric irregularities connected with the nighttime equatorial activity produce sufficient Doppler spread scattered energy that directly affects the performance of the radar. With the Parametric Ionospheric Model developed at the Phillips Laboratory and numerical ray tracing the specific interaction regions for the radar signal and the ionospheric irregularities are shown and an explanation for the observed temporal behavior is proposed. Several mechanisms for Doppler spreading of the clutter signal are also reviewed. Author

The electromagnetic wave propagation in the ionosphere is complex; the anisotropy and the inhomogeneity introducing multiple paths and the non stability of the Doppler effects. The ionospheric models usually used make it possible to account for the multiple paths and the Doppler shifts. According to these models, based on ray tracings, it appears that there is only one triplet (amplitude, Doppler, time travel) which makes it possible to plot simple diagrams. The experimental observation shows that, if one finds the signatures envisaged in the classical theory of the ray tracings for the signals of great amplitude, one observes, with systems of measurement of great sensitivity, signals of low amplitude which seem to translate the existence of diffuse propagations. The results of an oblique bistatic survey and of a backscattering study given in this presentation, show the appearance of effects of the second order. A method of characterization of these effects is proposed by the introduction of measurement of fractal dimensions of the functions of scattering, obtained by a method of high resolution spectral analysis. The performance of communications equipment (especially data modems) designed to work over high frequency paths which can propagate by a number of different mechanisms is dependent on their ability to work with a wide range of signal to noise conditions and with varying degrees of frequency and time dispersion. The latter phenomena are a particular problem for systems operating over high latitude paths and yet there appears to be little available data documenting their severity or frequency of occurrence. DAMSON (Doppler And Multipath SOunding Network) is an oblique channel sounding system which has been developed by the UK Defence Research Agency (DRA) to measure a number of real-time channel parameters using low power pulse compression waveform transmissions. Extensive use is made of digital signal processing techniques. The system will allow signal time-of-flight, time dispersion (multipath dispersion), frequency dispersion (Doppler spread and Doppler shift) and signal strength to be measured over point-point communications paths. The DAMSON experiment is to be deployed to make measurements over a number of mid and high-latitude paths. This paper provides an introduction to the DAMSON system, its basic operation and measurement performance. The initial experiments to be conducted and the associated system deployment are presented. We present a system which is able to separate the propagation paths and also to identify the type of polarization of the modes. The studied links are between Monterfil (48 deg 05 N latitude, 2 deg W longitude) and all types of known location transmitters which work on carrier. The experimental analysis is performed using a 'goniopolarimeter' which is a device determining both the arrival angles (goniometrical function) and the type of polarization of the corresponding incoming skywaves. We apply a high resolution non linear frequency analysis associated with a reiterated method of filtering matched to this polarization. Author (revised)

The paper introduces the principles of a new macroscopic diversity scheme employing maximum likelihood, symbol-level, diversity combining. The performance of the scheme is compared with that of other classical post-detector diversity combining methods. It is shown that the new scheme has a performance similar to the classical techniques; however, its complexity is significantly lower. The application of macroscopic diversity in the HF band is then described, and the results of practical on-air trials presented. Author

In this work three superresolution direction finding algorithms for use with arbitrary array geometries are described, all of which are capable of dealing with coherent signals, as typically found in the multi-path environment. DOSE is a quick single snapshot algorithm developed by the authors which operates on the received data vector. The IMP and Maximum Likelihood (ML) algorithms are used to process time averaged data covariance matrices. All three algorithms attempt in different ways to find a multi-dimensional solution to the inverse problem of direction finding. It is shown that calibration of arrays of identical elements is simplified by the use of these multi-dimensional algorithms when compared to 1 dimensional methods such as MUSIC. A common methodology for the implementation of these multi-dimensional algorithms is presented, and a quick method of implementing the ML algorithm and determining the number of signals present is described. In this paper, we present the use of high resolution techniques and polarization diversity in order to analyze HF links in ionospheric propagation, links which are characterized in general by the presence of several modes of propagation giving rise to several incident waves with the reception. These modes are strongly correlated and can have very different polarizations. The high resolution techniques have the capacity to simultaneously measure several incident waves present in a given frequency channel of analysis, and are thus adapted particularly to the situation of jamming where a frequency and/or temporal separation is no longer possible. The use of a network with polarization diversity allows, beyond obtaining certain parameters of polarization, an increase in the resolution of the methods considered, because of the difference in polarization of the modes. A better knowledge of the phenomenon of propagation waves in this medium is the anticipated result of the application of these techniques. For a given connection and at first approximation (one neglects the effects due to the 'tilt', or the rebound on a tilted ground), the modes arrive under the same azimuth with different angles of elevation. In the experiment described in this paper, the measurement of the angles of elevation is made by supposing a knowledge of azimuth. Thus we use a linear network and let us direct it in order to obtain good performances for the estimate of the angles of elevation. The method high resolution with diversity of polarization used is method MUSIC adapted in order to take account of the use of sensors having gains different according to polarization from the received wave. As part of the joint German/US SAXON-FPN remote sensing experiment a series of mm-wave radar backscatter measurements were carried out in the German Bight of the North Sea in November 1990, 1991 and August 1992. The dependence of the reflectivity sigma(sup o) on wind speed and direction was determined by means of a 94 GHz (W-band) radar mounted on the German Research Platform North Sea (FPN). The radar backscattering measurements were performed at an incidence angle of 45 deg and at azimuth angles relative to the wind direction ranging from upwind to crosswind. Based on the data evaluation of the three measurement periods values for the wind speed exponent gamma defined by an empirical relation between the reflectivity sigma(sup o) at vertical polarization and the windspeed U measured at a height of 46 m above mean sea level at the FPN were obtained. The values of gamma range between 2.33 and 2.50 depending on wind direction and the wave spectrum. This result shows that the wind speed exponent at W-band is higher than those at X-, Ku- and Ka-band indicating that either an enhanced generation of higher amplitudes of short waves in the millimeter range or other processes exist like specular scattering from facets reinforcing the backscatter cross section. The precise localization of the areas of the ionosphere by HF forward-scatter radars depends on the parameters characteristic of the propagation at the time of the survey, and often requires the use of calibration techniques. To gauge the data of the sounder with backscattering data from the Losquet Island, the National Center of Studies of Telecommunications (CNET) implemented a HF mobile monofrequency responder radar. This paper presents the results of surveys obtained in 'scanning of site' mode with this responder and established to approximately 1000 km the Losquet Island; these data are used to calculate the position of the responder. It is shown that the multipaths are the primary source of the statistical error of localization in radial distance and that the use of simple methods of treatment allows the reduction of this error. The MAMA (Mixed Arithmetic, Multiprocessing Array) module is being developed to evaluate new packaging technologies and processing paradigms for advanced military processing systems. The architecture supports a tight mix of signal, data,and I/O processing at GFLOP throughput rates. It is fabricated using only commercial-on-the-sehlf (COTS) chips and will provide a high level of durability. Its attributes are largely the result of two new interconnection and packaging technologies. Chip-in-board packaging is used to reduce local x-y communication delays and solder joints, while significantly improving board-level packaging density. A unique 3-D interconnection technology called a cross-over cell has been developed to reduce board-to-board communication delays, drive power, glue logic, and card-edge pin-outs. These technologies enable true 3-D structures that are form, fit and connector compatible with conventional line-replacable

modules. The module's design rational, packaging technology, and basic architecture will be presented in this paper. Author

Production of microelectronic devices encapsulated in solid, molded plastic packages has rapidly increased since the early 1980's. Today, millions of plastic-encapsulated devices are produced daily. On the other hand, only a few million hermetic (cavity) packages are produced per year. Reasons for the increased use of plastic-encapsulated packages include cost, availability, size, weight, quality, and reliability. Markets taking advantage of this technology range from computers and telecommunications to automotive uses. Yet, several industries, the military in particular, will not accept such devices. One reason for this reluctance to use the best available commercial parts is a perceived risk of poor reliability, derived from antiquated military specifications, standards, and handbooks; other common justifications cite differing environments; inadequate screens; inadequate test data, and required government audits of suppliers' processes. This paper describes failure mechanisms associated with plastic encapsulation and their elimination. It provides data indicating the relative reliability of cavity and solid-encapsulated packaging, and presents possible approaches to assuring quality and reliability in the procuring and applying this successful commercial technology. The objective of the 'Advanced SEM Processes' effort is to simplify the development and qualification processes and reduce the related process times and costs from the current way of doing business. Advanced technology developments and qualifications typically are completed in three to five years from conception. The Standard Hardware Acquisition and Reliability Program (SHARP) is working in conjunction with the Advanced Research Project Agency (ARPA) Application Specific Electronic Modules (ASEM) effort, Raytheon and the Electronics Manufacturing Producibility Facility (EMPF) Manufacturing Technology efforts to define new processes for development and qualification that leverage commercial and military technology in applying 'MultiChip Modules' (MCM's) to Standard Electronic Module format E (SEM-E) packaging. These processes are anticipated to have applicability to the development and qualification of SEM-E packaging, using multiple state of the art technologies in addition to MCM's. The primary objective is to reduce the current cycle time from three - five years to twelve months and costs from $500,000 - $1,000,000 to $100,00 - $250,000, therefore providing a baseline for standardizing electronics hardware acquisition processes into the twenty first century and beyond. ASSURING KNOWN GOOD DIE (KGD) FOR RELIABLE, COST EFFECTIVE MCMS
DANIEL E. DASKIEWICH *In* AGARD, Advanced Packaging Concepts for Digital Avionics 7 p (SEE N95-20631 06-06) Oct. 1994
(AGARD-CP-562) Copyright Avail: CASI HC A02/MF A03

A key requirement for achieving high yield multichip modules (MCM's) is assuring that the individual dice are known good devices (KGD). A KGD is defined as a bare die available at the same quality and reliability as the equivalent single chip packaged parts. Integrated circuits (IC's) that are Known Good will function over a specified temperature range, are compatible with the MCM approach utilized, and contain no short-term or long-term reliability hazards. The application of reliability and testability techniques at all levels of MCM development, particularly at the chip level, will maximize MCM yield. Today's testing and qualification requirements, defined by MIL-STD-883 Methods 5008 and 2010, are not capable of assuring KGD as defined above. The development of cost effective requirements for achieving 99.9 percent yields poses a challenge which requires new and novel approaches and better methods for bare die testing, wafer level burn-in, tape automated bonding (TAB), temporary packaging, at-speed device testing at the wafer, die, and MCM level. Also of great importance are the methods for built-in self test (BIST), built-in test (BIT), and boundary scan. New standards in very large scale integration (VLSI) device testing must be developed in order for MCM's to be reliable and economical. Rome Laboratory (RL) has funded a program to address and develop these requirements. The objectives of the RL program are to: research and evaluate current and proposed burn-in, electrical and interconnect test techniques for assuring known good VLSI circuits at wafer and die level; and evaluate various methods of incorporating testability features which will decrease test time and cost. In addition, MCM-level reliability and performance assessment procedures will be evaluated to determine appropriate testing concepts and procedures that will assure the procurement of reliable, cost effective MCM's for DOD/NASA applications. The program consists of two phases: Phase One will be a study phase to evaluate, analyze, trade-off, and select best techniques for test and burn-in of wafers, bare die and MCM's. Phase Two will be a demonstration of a cost effective procedure for assuring high quality/reliable production of MCM's based on the KGD methods developed in Phase One. Author

THE DESIGN AND MANUFACTURING DEVELOPMENT OF AN ACTIVE SILICON SUBSTRATE MCM
M. G. ROUGHTON and L. WAITE *In* AGARD, Advanced Packaging Concepts for Digital Avionics 7 p (SEE N95-20631 06-06) Oct. 1994 Sponsored by DTI
(AGARD-CP-562) Copyright Avail: CASI HC A02/MF A03

The demand for engine control systems with reduced weight, size and cost, increased integration, improved reliability and higher temperature operation drives the system designer to the use of advanced hybrid assembly technologies. This paper describes the design and manufacturing development of a silicon based 'D' type multichip module, MCM, containing an active substrate of memory. This CPU module is one of the building blocks for a range of generic engine control systems. The active substrate approach potentially gives higher packing density than wafer scale due to its 3D configuration. The active substrate comprises 12 SRAM 128K x 8 bit of diffused memory arranged in groups of three. The design is organized so that a 'memory manager' ASIC selects pages of good memory from the substrate die thus obtaining the best possible yield. A single wafer contains 4 silicon hybrid substrates, each approximately 40mm sq, which will be processed before separating into discrete circuits. The MCM structure is comprised of four aluminium metallization layers with benzocyclobutene, BCB, as the dielectric. Approximately 16 other devices including a processor, the 'memory manager' ASIC, a Processor Support ASIC and EDPROM, plus resistor network chips and decoupling capacitors will be added to the silicon substrate using adhesive and wire bond interconnection. The 'memory manager' ASIC tests the RAM on power-up, reject areas of bad memory and configures the good areas such that a continuous block of functional RAM is available to the processor. The RAM is configured as a 16 bit wide with both 16 bit and 8 bit read/write accesses being supported. The total module is to be assembled in a high temperature co-fired ceramic package with 200 I/O. After test and any rework that may be necessary the package will be sealed with a Kovar lid ready for final test. Author

This paper presents an active matching technique for extending the data rates of electrical backplane interconnects into the gigabit per second (Gb/s) range. In the active matching technique an active bandpass amplifier is used to drive the backplane

transmission lines. The gain characteristic of the amplifier is designed to be complementary to that of the transmission line and connectors using standard microwave matching techniques. This technique is suitable for use with conventional stripline and microstrip backplanes as well as newer microcoaxial cables. Using this technique, backplanes operating at serial data rates in excess of 4 Gb/s have been demonstrated and speeds of 10 Gb/s may be possible. These results suggest that electrical backplanes may be competitive with optical backplanes in speed and superior to them in cost, power consumption, and complexity. Author

The symposium was composed of the following sessions: turbomachinery computations and validations; flow in ducts, intakes, and nozzles; and reacting flows. Forty papers were presented, and they covered full 3-D code validation and numerical techniques; multidimensional reacting flow; and unsteady viscous flow for the entire spectrum of propulsion system components. The capabilities of the various numerical techniques were assessed and significant new developments were identified. The technical evaluation spells out where progress has been made and concludes that the present state of the art has almost reached the level necessary to tackle the comprehensive topic of computational fluid dynamics (CFD) validation for propulsion. For individual titles, see N92-27451 through N92-27490.

S1BYL2 is an inviscid-viscous blade-to-blade method for calculating the detailed aerodynamics and overall performance of compressor blades. It may be applied either on its own to predict the flow for individual blade sections, such as the midspan of a linear cascade, or in conjunction with a throughflow calculation to predict the performance of a complete axial compressor. New predictions for the V2 and ARL SL19 cascades and for the high speed compressor cases are presented. It is hoped that this will be one of many sets of calculations for these cases, so that an improved understanding of each case may be obtained, together with an appreciation of the strengths and weaknesses of different computational approaches. A computational study of 3-D flow in the Virginia Polytechnic Institute and State University (VPI&SU) tip leakage turbine cascade is used to show the level of modeling attainable now. Results for the overall flow development are compared with measurements of flow and losses at the exit of the tip leakage gap and downstream of the blade row. Mechanisms for the additional loss due to tip leakage are discussed. Consideration is given to areas where the modeling of fine scale flow structure may be improved. These include the flow in the tip clearance gap, flow in the tip leakage vortex, and flow separation at the trailing edge. Author

Compressible rotational flows in curved ducts due to inlet total pressure gradients are analyzed. Two different time-marching methods are briefly presented and utilized for the analysis of the development of 3-D flows. The former is a finite volume explicit method, and the latter is a finite difference implicit method. These methods are successfully compared to each other and with other methods. A first analysis of secondary flows concerning constant section curved ducts with a curvature of 90 degrees is performed. Author

Two dimensional Navier-Stokes solvers are beginning to appear for the purpose of analyzing fluid flow and heat transfer phenomena in turbomachinery. It is often assumed that the Navier-Stokes equations represent the ultimate in precision and generality possible when the fluid is modeled as a continuum. Therefore, the advent of the high-speed computer has spawned a number of finite differencing schemes aimed at solving these equations for steady and unsteady flows, both internal and external. In the case of compressible flows with heat transfer, some of these schemes have had questionable success in the approximation of experimental data despite use of accepted solution techniques and reasonable care in maintaining rigor in boundary conditions. Stoke's hypothesis, with its implication of zero bulk viscosity for a

viscous fluid, may have a bearing on some of these anomalies. Two viscous, compressible flow phenomena, in the form of expansion waves, for which the level of irreversibility implied by Stoke's hypothesis appears to be suspect. Author

The mechanism of film cooling and heat transfer on gas turbine blades and end walls is theoretically investigated by simultaneously solving the 3-D Navier-Stokes equations for the flow field and the 3-D heat conduction equation for the cooled blade. The coupling of flow calculation and heat conduction calculation in the turbine blades supplies the wall temperatures and heat fluxes at the blade surfaces. These have to be taken from measurements if a traditional boundary layer approach is used for calculating the corresponding heat transfer coefficients. Heat transfer coefficients and film cooling efficiencies resulting from the 3-D solution are presented. Additionally, a comparison between measured and calculated data is shown. Author

A Navier-Stokes computer code was used for the calculation of the 3-D secondary flow in a cascade of axial turbine blades. A comparison is made with experiment of the results of various applications of a mixing length model within the code. The results are compared on the basis of mean flow data and also turbulent Reynolds shear stresses. Substantial grid independence was obtained with a grid of 20,000 points; further grid refinement had a significant effect only on midspan loss. Large variations in the results were obtained with laminar flow being imposed for up to 80 percent of the axial chord away from the end wall. The high turbulence activity in the vortex core was not predicted; the flow close to the endwall and blade surfaces appeared to dominate the calculated flow. The need for higher order turbulence modeling is indicated, but probably of greater importance is the accurate prediction of transition. Author

A number of researchers have suggested using an inter-blade row boundary condition to extend isolated blade row flow solvers to multiple blade row configurations. This suggestion is worth consideration for it appears to result in codes that are computationally more efficient than those based on other schemes that were suggested to accomplish the same task. The work is concerned with the development of a mathematical constraint which this boundary condition must satisfy to insure the proper transfer of momentum and vorticity across the plane. Using experimental data, the work quantifies the error in the time-averaged vorticity field which results from simply requiring continuity across the boundary plane of the momentum based on the time-averaged velocity fields associated with a multiple blade row configuration. A methodology is presented for unsteady flow analysis in vibrating transonic compressor cascades, using Euler equations. After a brief discussion of the problem, the numerical algorithm is presented, for the 3-D case, with particular emphasis on grid displacement procedures, slip surface fitting, boundary conditions, and their effect on computational results. Chorochronic flow periodicity and model superposition are briefly discussed. Several results from realistic aircraft engine turbomachinery configurations are presented. The lack of, and urgent need for 3-D experimental data combining unsteady pressure measurements and vibrating mode shapes are stressed. The methods are then validated through comparison with time linearized flat plate cascade theory (analytical) and experimental data from annular and linear cascades. A method for computing the aeromechanical coupling is presented. Finally, a discussion is presented of viscous effects. Author

In order to solve industrial flow problems in complex geometries, a finite element code, N3S, was developed. It allows the computation of a wide variety of 2-D or 3-D unsteady incompressible flows, by solving the Reynolds averaged Navier-Stokes equations together with a k-epsilon turbulence model. Some recent developments of this code concern turbomachinery flows, where one has to take into account periodic boundary conditions, as well as Coriolis and centrifugal forces. The numerical treatment is based on a fractional step method: at each time step, an advection step is solved successively by means of a characteristic method; a diffusion step for the scalar terms; and finally, a Generalized Stokes Problem by using a preconditioned Uzawa algorithm. The space discretization uses a standard Galerkin finite element method with a mixed formulation for the velocity and pressure. An application is presented of this code to the flow inside a centrifugal pump which was extensively tested on several air and water test rigs, and for which many quasi-3-D or Euler calculations were reported. The present N3S calculation is made on a finite element mesh comprising about 28000 tetrahedrons and 43000 nodes. Author

A 3-D flow analysis code was used to compute the design speed operating line of a transonic fan rotor, and the results were compared with experimental data. The code is an explicit finite difference code with an algebraic turbulence model. The transonic fan, called Rotor 67, was tested experimentally at NASA Lewis conventional aerodynamic probes and with user anemometry and was included as one of the AGARD test cases for the computation of internal flows. The experimental data are described. Maps of total pressure ratio and adiabatic efficiency vs mass flow were computed and are compared with the experimental maps, with good agreement. Detailed comparisons between calculations and experiment are made at two operating points, one near peak efficiency and the other near stall. Blade-to-blade contour plots are used to show the shock structure. Comparisons of circumferentially integrated flow quantities downstream of the rotor show spanwise distributions of several aerodynamic parameters. Calculated Mach number distributions are compared with laser anemometer data within the blade row and the wake to quantify the accuracy of the calculations. Particle traces are used to show the nature of secondary flow. Author

A three dimensional Navier-Stokes analysis of heat transfer and aerodynamic performance is presented for a low speed linear turbine cascade. The numerical approach used consists of an alternate direction, implicit, approximate factorization, time marching technique. An objective was to establish the computational grid density requirements necessary to accurately predict blade surface and endwall heat transfer, as well as the exit plane aerodynamic total pressure loss and flow angle distributions. Also, a study was performed to determine a viable implementation strategy for the 3-D modeling of transition and turbulence in the turbine blade passage. Results are presented which show that the present procedure can accurately predict 3-D turbine blade heat transfer as well as the absolute level and spanwise distribution of aerodynamic performance quantities. An implicit finite difference algorithm is presented which solves the unsteady Euler equations in three dimensional ducts. The Helmholtz decomposition is examined of the unsteady velocity field into a potential and a rotational part. The geometry does not change with time, thus the unsteady nature of the flow is due to the time dependent inflow and outflow boundary conditions. The flow at the inlet is supposed to be rotational. Vorticity is introduced by means of velocity, total enthalpy, or even entropy profile slope. The results cover a wide range of reduced frequencies in the subsonic flow regime. Author

Three-dimensional flows around civil engine intakes were calculated by a Navier-Stokes method. The full Reynolds-averaged Navier-Stokes equations for viscous flow are solved by an explicit time-marching cell-centered finite-volume algorithm. To ensure numerical stability, Jameson's formulation of fourth-order and second-order smoothing is used. Second-order smoothing is switched on only in regions of strong pressure gradient such as shocks. The flow may be laminar or turbulent; turbulence is treated by a mixing-length eddy viscosity model. The algorithm is applied on a body-fitted C-type computational grid. Author

Above certain Mach numbers, flows in wind tunnels can no longer fully simulate the actual flow physics. In the design of optimal propulsion systems, which are capable of economically propelling aircraft to hypersonic Mach numbers, understanding of the 'real' flow is mandatory. This paper will address recently developed numerical elements of an advanced CFD code in terms of computational speed and accuracy. Results will be presented of several calculations performed to gain insight into the flow in hypersonic intakes. Author

The numerical solutions for internal three-dimensional Euler flows were obtained by using a cell-vertex finite volume method. The solver which was developed, was applied to a wide range of subsonic, transonic, and supersonic test cases, among which, are the Ni-bump channel, the supersonic wedge cascade, and the 90 degree bend channel. A second order accurate, one-step Lax-Wendroff scheme was used to solve the unsteady equations, discretized in strong conservation form. Characteristic boundary conditions were used along with appropriate artificial viscosity and smoothing models. The results illustrate the established flow symmetry in a subsonic Ni-bump channel, the shock - boundary interaction in transonic and supersonic Ni-channels and wedge cascade, and finally, the secondary flow within a 90 degree bend channel. Despite the wide range in the Mach number and the diversity of flow geometries which were tested, close agreement was obtained with available analytical and numerical results associated with these test cases. A numerical representation of three dimensional turbulent flow within cooling ducts located in turbine blades and heat transfer into such ducts is effected using the finite element method. The importance of a coupled solid/fluid numerical model, when investigating heat transfer, is demonstrated by comparing numerical results with experimentally determined values relating to smooth,

cylindrical rotating passages. Having verified the numerical model, the technique is then used to evaluate heat transfer into a multi-ribbed rotating cylindrical duct. The enhancement of heat transfer, due to Coriolis induced secondary motion and the incorporation of ribs, is predicted and compared with experimental measurements. Author

Most of the flow geometries for aeronautical engineering are complex and cannot be discretized using orthogonal coordinates. In addition, some of those flows can only be described in the fully developed form of the Navier-Stokes equations. In this paper the Navier-Stokes equations are solved for three-dimensional complex geometries using a non-orthogonal, non-staggered coordinate system. The strong conservation form of the governing equations for laminar flows is discretized using a finite volume method. A numerical grid generation method is employed in order to easily generate the meshes. The flow through a square diffuser, the flow through a transforming duct of elliptical cross-section, and the flow through a square cross-section S-shaped duct were analyzed. The predictions reveal good agreement with the available data demonstrating the accuracy and generality of the present method. The present solution algorithm can easily be extended to calculate subsonic compressible flows. Author

Aerodynamic losses incurred in gas turbine ducting are often substantial, contributing in a significant way to the overall compression or power loss. A finite element Navier-Stokes compressible turbulent code, NS3D, was under development between Pratt & Whitney Canada and Concordia University to help in the understanding of the flow field in such ducts and diffusers, in order to control the loss mechanisms. The code is based on a Newton-Galerkin finite element method, with equal order interpolation for velocities and pressure. The system of linear equations, at each Newton iteration, is solved for the primary variables (u,v,w,p) simultaneously, with either iterative methods designed to run on engineering workstations or with direct methods on supercomputers. Turbulence is modeled through the well-known (k, epsilon) model, with wall functions. The code was applied to the compressible turbulent analysis of intercompressor ducts and diffusers, and compares reasonably well to experiments. In addition, the code is being used to obtain improvement of duct performance through numerical redesign. Author

One of the major tasks for the development of novel airbreathing space transportation systems, operating from usual airports by horizontal take off and landing, is the integration of an advanced propulsion system in the cell of that spacecraft. The air intake and in particular the free expansion nozzle affect not only the efficiency of the engine but also the forces and moments, and with that, the control of the complete spacecraft. Therefore, it is necessary to know in detail the flow fields through such nozzles and its interaction with the external airflow. Another project deals with conventional rocket motor nozzles whereby injection of turbine exhaust gases in the expansion part of the nozzle the wall of the nozzle is cooled (filmcooling concept) and the thrust is slightly increased. Theoretical investigation of these and other nozzles is the objective of this paper. Euler and boundary layer methods will be applied to predict the flow fields of the nozzles where special emphasis is laid on the consideration of real gas effects. The theory of the Euler method will be described in detail while for the second order boundary layer method the governing equations are presented and the range of its applicability is shortly discussed. Finally results for a variety of nozzles will be given. Author

The paper considers the computation of turbulent flow through circular sectioned S-bends, a flow generically similar to those arising in various types of jet-engine intake ducting. A fully elliptic, finite-volume discretization of the Reynolds equations is adopted. For the main part of the flow the standard algebraic second-moment (ASM) closure is adopted while over the thin, viscosity-affected

sublayer, adjacent to the wall, three types of model were explored: namely, one- and two-equation eddy viscosity models and a two-equation ASM closure. Although the main features of the flow development are well captured even with the simplest near-wall treatment, the pressure drop through the second half of the S-bend is seriously underestimated. The successive refinement of the model across the sublayer is found to bring the computed behavior into very close accord with the detailed experimental data. The findings indicate the desirability of using a high-level turbulence model not just in the main part of the flow but across the low-Reynolds-number sublayer also. Author

THREE DIMENSIONAL FLOW IN SHARP BENDS

K. FOTEA, P. PRINOS, and A. GOULAS *In* AGARD, CFD Techniques for Propulsion Applications 12 p (SEE N92-27450 18-34) Feb. 1992

(AGARD-CP-510) Copyright Avail: CASI HC A03/MF A06

The three dimensional flow in sharp bends is computed by solving the fully elliptical three dimensional Navier-Stokes equations in conjunction with a k-epsilon model of turbulence. Computed isovelocity patterns before and after the sharp bend and recirculation lengths are compared with experimental measurements taken with Laser Doppler Anemometry. In general good agreement is obtained although the refinements in the turbulence modelling can improve the predictions. The computational results show that the recirculating region depends strongly on the inlet velocity profile. Finally, an increase in the aspect ratio of the duct indicates an increase of the region of the recirculation. Author

(AGARD-CP-510) Copyright Avail: CASI HC A03/MF A06

To increase the temperature mixing efficiency in the common nozzle of an existing turbofan engine, a forced mixer is to be developed. Its design is based on empirically derived knowledge and requires some verification testing. To minimize the scope of testing, a numerical investigation has been performed, computing the complete flow path through the mixer up to the thrust nozzle. The computational domain is formed by a body fitted H-type grid. The simulated air flow is compressible adiabatic including variable specific heat and viscosity and the standard k-epsilon model is used. Resulting velocity and temperature fields are presented together with the temperature mixing efficiency. Use of the velocity field to shape the scallops at the mixer trailing edge is demonstrated. Comparison with test results indicates that computational fluid dynamics (CFD) is a useful engineering tool to check and improve a new design before testing. Author

FLOW COMPUTATION IN COMBUSTION CHAMBERS USING ZONAL NONSTAGGERED GRIDS

M. RACHNER *In* AGARD, CFD Techniques for Propulsion Applications 18 p (SEE N92-27450 18-34) Feb. 1992

(AGARD-CP-510) Copyright Avail: CASI HC A03/MF A06

A Rhie-type nonstaggered grid three dimensional Navier-Stokes Code working on overlaid subdomains by a zonal technique is applied on two model combustion chambers. In the case of the swirling turbulent combustor flow investigated, a locally unrealistic flow behavior at domain boundaries was found on the coarse grid. This is caused by strong overshoots of the momentum interpolated cell mass fluxes, not reported up to now in the literature. The influence of the pressure gradient discretization at boundaries on these overshoots is shown. At inter grid boundaries the discretization of the pressure gradient can give rise to wiggles in the numerical solution as observed in the case of the reacting turbulent crossflow-H2-jet in a rectangular channel. Moreover the influence of fully, partially and lacking local flux conservativity in coupling the numerical fluxes across inter grid boundaries of the subdomain is studied. The fully conservative coupling scheme turned out be a nonrobust method. Author

A Monte Carlo technique is outlined for the simulation of the transport of a joint scalar probability density function (PDF). The discretization of the partial differential equations is based on a finite volume approximation. The problem of frozen solutions is addressed if the number of stochastic elements is limited. Non-adiabatic boundary conditions are discussed if the energy equation is solved by a Monte Carlo simulation. The Monte Carlo simulation is compared with deterministic calculations and with an experiment in a three dimensional non-isothermal non-reacting jet mixing flow. The results of the simulation agree very well with the experiment and the deterministic calculations. However, the computer time and storage requirements for a three dimensional simulation of the transport of a single scalar PDF increases dramatically in comparison to deterministic calculations. The results also indicate the need for a simulation procedure that is free of numerical diffusion. Author

The hypersonic nonequilibrium flow of air through inlets of propulsion devices is investigated. The fluid dynamics is described by the Euler equations and a chemical model accounts for finite rate equations. The numerical procedure is based upon a space marching technique, under the hypothesis of fully developed supersonic flow. The conservative form of the Euler and finite rate chemical equations are integrated, following a finite volume discretization and a flux difference splitting procedure. The numerical scheme is of the second order accuracy, with a proper total variation diminishing (TVD) technique to avoid spurious oscillations at flow discontinuities. Numerical results are presented and discussed. Author

EVALUATION OF THE EFFECTS OF FINITE RATE CHEMISTRY ON NOZZLE PERFORMANCE

M. ONOFRI *In* AGARD, CFD Techniques for Propulsion Applications 11 p (SEE N92-27450 18-34) Feb. 1992

(AGARD-CP-510) Copyright Avail: CASI HC A03/MF A06

Predictions of nozzle performance may be strongly affected by the choice of the flow model: large discrepancies with actual behaviors could occur if the two dimensional gasdynamic effects and the variations of chemical composition are not suitably accounted for, especially when the nonequilibrium region is wide enough and two dimensional gasdynamic phenomena interact significantly with chemical kinetics. In order to assess the accuracy of different simulations, a comparison among inviscid numerical solutions is performed for different classes of axisymmetric nozzles. The roles of the two dimensional effects on the global propulsive parameters is analyzed by comparing one and two dimensional solutions, while their influence on chemical kinetics is evaluated by considering frozen and nonequilibrium flow models. The numerical solution of the nonequilibrium nozzle flow model is performed by an implicit integration technique based on an operator splitting between gasdynamics and chemistry. While gasdynamics equations are integrated by the fast solver, the energy and mass fraction conservation equations are integrated in steady form along streamlines with a variable step procedure. This approach yields very efficient and accurate solutions even when the chemical variables display steep gradients. Author

The converging-diverging nozzle geometries, which are presently proposed for hypersonic propulsion systems, are characterized by large expansion area ratios, and by a geometrically variable nozzle throat to control the engine mass flow. Within the expanding nozzle flow, chemical recombination reactions of the combustor exhaust gas products will occur; the limited chemical reaction rates generally leading to a relaxation of the chemical species composition. In addition, changes in mixture composition and heat release due to chemical reactions influence the flow field. Based on Moretti's lambda-scheme a numerical model was developed which couples the gasdynamic phenomena with the chemistry effects that occur within the flow field. The chemical reaction rates are described by a kinetic model involving a satisfactory reaction mechanism. The developed scheme was applied to the expanding nozzle flow of a stoichiometric H2-air exhaust gas. For comparison, four different physical models have been considered to describe the chemical phenomena: chemically frozen flow; flow in chemical equilibrium; chemical equilibrium upstream of nozzle and nonequilibrium downstream of the nozzle; and flow in chemical nonequilibrium. The results are discussed in terms of flow properties, gas mixture composition, and nozzle exit momentum. It is concluded that a physically inadequate model of the chemical phenomena will lead to unacceptable discrepancies in net engine thrust predictions. Author

Some three dimensional calculations have been performed in order to predict the reactive flow within aircraft combustion chambers. Two kinds of combustion models have been tested: on one hand a model which makes the assumption of fast chemistry but can however take roughly into account some aspects of the chemical kinetics through an ignition delay and, on the other hand, the Lagrangian-Eulerian PEUL model which can deal directly with some Arrehenius laws by means of the interaction by exchange with the mean (IEM) submodel and hence does not include some assumptions of fast reaction. SPECIAL COURSE ON UNSTRUCTURED GRID METHODS FOR ADVECTION DOMINATED FLOWS
May 1992 362 p Special course held in Rhode-Saint-Genese, Belgium, 2-6 Mar. 1992 and at Moffett Field, CA, 28 Sep. - 2 Oct. 1992; sponsored in cooperation with VKI
(AGARD-R-787; ISBN-92-835-0671-5; AD-A256061) Copyright Avail: CASI HC A16/MF A03

Lecture notes for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Unstructured Grid Methods for Advection Dominated Flow' have been assembled in this report. The objective of this course was to provide state of the art information, as well as recent developments in unstructured grid methods, suitable for the computation of high Reynolds number compressible and incompressible flows, and other related subjects. A wide range of applications is presented, which includes incompressible free surface problems, transonic aerodynamics, and hypersonic reentry flows. For individual titles, see N92-27672 through N92-27680.

The purpose of this note is to give an overview of the Streamline Diffusion Method (SDM), also referred to as Galerkin/Least Squares or Streamwise Upwind Petrov-Galerkin (SUPG), as a general finite element method for hyperbolic type differential equations modelling convection-diffusion, compressible/incompressible fluid flow or wave propagation. The SDM developed gives the first general solution to the fundamental problem of constructing finite element methods for hyperbolic problems with the desired combination of good stability and high accuracy. The SDM is a modified Galerkin method based on piecewise polynomial approximation with two modifications: a 'streamwise diffusion' modification of the test functions giving a weighted least squares control of the residual of the finite element solution; and the introduction of an artificial viscosity. In these lecture notes we review some of the recent progress on stabilized finite element formulation used in computation of incompressible flows. The stabilization techniques emphasized in these lecture notes are the Galerkin/least-squares, streamline-upwind/Petrov-Galerkin, and pressure-stabilizing/Petrov-Galerkin formulations. Most of the examples considered are unsteady flow problems, with emphasis on moving boundaries and interfaces, such as free surface flows, liquid drops, flow past an oscillating cylinder, and flow past an oscillating airfoil. Also reviewed are the iteration strategies employed to solve the implicit equation systems resulting from the finite element discretization of these flow problems, including space-time formulations. The lecture notes also describe a new mixed clustered-element-by-element (CEBE/CC) preconditioning method for finite element computations. Author

In this contribution we describe a class of upwind schemes for hyperbolic conservation laws on unstructured grids consisting of triangles or tetrahedrons. Unlike standard upwind schemes which are based on a one dimensional physical model (the Riemann problem), the methods discussed here use a multidimensional

physical model for the upwinding. They do not fit in a standard finite volume approach with piecewise continuous representation of the unknowns. In this respect they are much closer to finite element methods based on linear elements, with which they share a continuous piecewise linear representation over the triangles or tetrahedrons. On the other hand they share with standard upwind methods the properties of asymmetric upwinded stencils and control of monotonicity over discontinuities, and they can be considered as truly multidimensional generalizations of the successful TVD upwind methods developed during the eighties. The implementation of the finite element method on unstructured triangular grids is described and the development of centered finite element schemes for the solution of the compressible Euler equation on general triangular and tetrahedral grids is discussed. Explicit and implicit Lax-Wendroff type methods and a method based upon the use of explicit multistep timestepping are considered. In the latter case, the convergence behavior of the method is accelerated by the incorporation of a fully unstructured multigrid procedure. The advancing front method for generating unstructured grids of triangles and tetrahedra is described and the application of adaptive mesh techniques to both steady and transient flow analysis is illustrated. One of the major achievements in engineering science has been the development of computer algorithms for solving nonlinear differential equations such as the Navier-Stokes equations. In the past, limited computer resources have motivated the development of efficient numerical schemes in computational fluid dynamics (CFD) utilizing structured meshes. The use of structured meshes greatly simplifies the implementation of CFD algorithms on conventional computers. Unstructured grids on the other hand offer an alternative to modeling complex geometries. Unstructured meshes have irregular connectivity and usually contain combinations of triangles, quadrilaterals, tetrahedra, and hexahedra. The generation and use of unstructured grids poses new challenges in CFD. The purpose of this note is to present recent developments in the unstructured grid generation and flow solution technology. HIGHER ORDER UPWIND FINITE VOLUME SCHEMES WITH ENO-PROPERTIES FOR GENERAL UNSTRUCTURED MESHES
P. VANKEIRSBILCK and H. DECONINCK *In* AGARD, Special Course on Unstructured Grid Methods for Advection Dominated Flows 54 p (SEE N92-27671 18-34) May 1992 Sponsored in part by Avions Marcel Dassault and Belgian National Fund for Scientific Research
(AGARD-R-787) Copyright Avail: CASI HC A04/MF A03

This contribution presents high resolution upwind finite volume schemes based on a polynomial reconstruction of the unknowns on unstructured polygonal cells. The schemes are essentially non-oscillatory (ENO) through the use of an adaptive stencil selection. A complete analysis and comparison given in this text shows that the order of the space accuracy of the schemes is at least equal to the degree of the reconstruction polynomial. Numerical results are shown for a nonlinear hyperbolic conservation equation, confirming the ENO shock capturing and higher order accuracy on highly irregular grids. More realistic Euler calculations will demonstrate the ability of the concepts that are outlined theoretically. Author

Numerical methods for the solution of field problems using unstructured grids have reached a high degree of maturity. Although computational fluid dynamics (CFD) have been dominated by structured grids, with the increase in computational ability, unstructured grids have started to have an impact on complex geometrical problems in CFD. The following paper describes grid generation, adaptive refinement schemes, visualization and parallelization issues. It also includes a short chapter on CFD among related disciplines that will help the newcomer with flow simulation codes. H.A.

A new algorithm for the generation of the interior nodes for Delaunay triangulation is given. The method uses a background grid to interpolate local mesh size parameters that are taken from the triangulation of the given boundary nodes. Geometric criteria are used to find a set of nodes in a frontal manner. This set is subsequently introduced into the existing mesh, thus providing an updated Delaunay triangulation. The procedure is completed when no more improvement of the grid by inserting new nodes can be achieved. Author

The objective of the symposium was to review the state-of-the-art in aerodynamic engine/airframe integration techniques and to report on the progress which has been achieved during engineering project work in recent years. Because the treatment of this subject requires an interdisciplinary approach, both experimentalists and theoreticians were invited to contribute to the meeting. Six sessions were organized to cover the essential subdisciplines requiring aerodynamic engine/airframe integration during the concept-assessment and design phases for new aerospace vehicles. For individual titles, see N93-13200 through N93-13231.

The paper traces a path through modern experimental techniques in use for the study of installation performance in the

context of military and civil engine/airframe integration studies. For military and civil transport designs it is shown that separate treatment of air intake and exhaust regions is generally undertaken in contemporary methods. An early entry into the aerodynamics of the complete engine/airframe is emphasized in order to avoid costly integration difficulties. Using examples largely drawn from direct experience gained during the period 1960 to 1990 the author presents a set of 'most preferred methods' for use in high speed configuration development model tests. It is noted that current trends in civil and military designs require increased attention to be paid to off-axis thrust/drag/lift variations in the engine/airframe integration process. Methods of flow visualization are briefly reviewed and the emerging laser methods are also identified. The paper closes with a conceptual configuration for a year 2000 totally integrated engine/airframe to meet 21st century civil transport mass transit requirements. Author

With the aim of reducing the number and the cost of its tests, SNECMA obtained a three-dimensional Euler code. This code solves the Euler compressible equations put into conservative form, and at convergence is able to predict the aerodynamic flows around complex multidomain geometries. The numerical algorithm is of the finite volume type and is second order in time with a 2-step predictor-corrector approach. In addition, it uses a local time step and an artificial viscosity of the TURKEL-JAMESON type. This method was validated by calculations on isolated nacelles and the numerical results obtained reflected in a satisfactory manner those resulting from the tests. This code has been industralized and today allows the analysis of the aerodynamic lines of nacelles. Transl. by FLS

With the development of Ultra-High Bypass (UHB) engines the aerodynamic interference between airframe and engine becomes increasingly important. In this study the solution of the Euler equations is used to simulate the flow field around the DLR-ALVAST wing-body combination with different wing-mounted engines. For a CFM-56 engine, which is taken here to represent a conventional engine, the contributions of single components like engine, pylon, and jet to the aerodynamic interference were investigated. The comparison with the flow field around the wing-body combination without engine showed that the presence of the engine alone lead to a forward movement of the shock on the complete upper surface of the wing. The pylon mainly influenced the lower surface and caused an additional loss of lift which is of the same order of magnitude as the loss due to the engine. The simulation of an inviscid jet showed no significant influence for the conventional engine. A further comparison of the interference effects of the CFM-56 engine and a UHB engine was made. The geometry of the UHB engine corresponds to the DLR-CRUF simulator for Ultra-High Bypass engines. Due to the closer installation to the wing and the larger dimensions, the UHB engine caused a local flow acceleration on the lower surface of the wing. This lead to a significant loss of lift at the engine position, compared to the conventional engine. Simulation with and without jet revealed that the jet was mainly responsible for this behavior. In case of the UHB engine the jet passed very closely under the wing and the displacement effect of the jet caused a strong flow acceleration. Author

A three-dimensional general multi-block Euler solver (GMBE) has been developed to analyze the propulsion integration effects of turbofan/superfan installations. Either flow-through or powered nacelles can be modelled. The code is demonstrated on a generic NASA low wing transport model with an advanced turbofan flow-through nacelle. The results compare favorably with experimental data obtained in the NASA Langley 16-Foot (4.88 m) Transonic Tunnel. The computed pressure distributions are used to identify, in terms of pressure coefficient peaks (maximum negative values) and gradients, undesirable flow regions in the vicinity of the pylon and nacelle. The results suggest that a change in toe angle and pylon trailing edge closure geometry will improve the propulsion integration. Author

Aero engine component design and development makes increasing use of computer codes for flow field calculations, such as two- or three-dimensional flow fields and flow fields with strong viscous effects. The accuracy of these calculation methods

depends on the mathematical models and numerical schemes used to describe the physical reality. The proof of validity and the refinement of such methods depend on verification against relevant test cases, primarily experimental test cases. The AGARD Propulsion and Energetics Panel established Working Group 18 to specify relevant reference test cases to serve as validation bases for new methods, but also as check for existing production codes. The present paper gives an overview on the results of the Working Group and briefly describes the different test cases. These test cases refer to analytical and experimental test cases for steady flow in linear compressor and turbine cascades, single blade rows, single and multistage axial compressors and turbines and ducts. In addition, suggestions for future tests designed to reduce the limitations are discussed. Author

This is part of the PEP contribution to the 69th FDP meeting on Aerodynamic Engine/Airframe Integration for High Performance Aircraft and Missiles. It presents an overview of the main outcomes of the last PEP meeting dealing with CFD techniques for propulsion applications. The emphasis was given to computational work on realistic 3D configurations, covering the four following topics: full 3D validations; full 3D numerical techniques; unsteady flows and multidimensional reacting flows. In addition, an invited paper from FDP on the state of the art of computational techniques for 3D Navier-Stokes equations and a technical evaluation of the meeting were presented. The most widely stressed conclusion was the urgent need for a large scale effort on validation of numerical accuracy and of physical models. Author

THE INFLUENCE OF INTAKE SWIRL DISTORTION ON THE STEADY-STATE PERFORMANCE OF A LOW BYPASS, TWIN-SPOOL ENGINE
W. MEYER, W. PAZUR (Universitaet der Bundeswehr Muenchen, Neubiberg, Germany), and LEONHARD FOTTNER (Universitaet der Bundeswehr Muenchen, Neubiberg, Germany) *In* AGARD, Aerodynamic Engine/Airframe Integration for High Performance Aircraft and Missiles 20 p (SEE N93-13199 03-34) Sep. 1992
(AGARD-CP-498) Copyright Avail: CASI HC A03/MF A04

Intakes of supersonic aircraft can produce intake swirl configurations in front of the engine which are important for intake/engine compatibility assessment throughout the flight envelope. The main objective of this investigation was to get more information about the influence of intake twin swirl on the steady-state engine behavior. The twin swirl was simulated using a movable delta wing positioned between the bellmouth intake and the engine. By changing the angle of attack of the delta wing, the intensity of the intake swirl could be varied. Increasing the intensity of the twin swirl resulted in a deterioration of engine performance. The analysis of the test results showed that these effects on engine performance were mainly due to a modified characteristic of the low pressure compressor (LPC). Therefore, it was very important to investigate the changed LPC performance to be able to understand the effects of an intake swirl distortion on the engine performance. Hence, an experimental method was set up to measure the performance map of the installed LPC by defined changing of the engine operating line. An analysis of experimentally determined compressor maps for varying intensities showed that the performance parameters of the LPC decrease. However, there is essentially no variation of the engine's working line due to an intake twin-swirl distortion. Semi-empirical calculations which took account of this influence of the generated swirl on the performance of the LPC confirmed the loss of engine performance observed during the engine tests. Some experimental studies of inlet/airframe interference, conducted at the Aermacchi's Water Tunnel facility about aircraft configurations under consideration for an Advanced Trainer Project, are presented. The chin inlet and the bifurcated inlet configurations have been considered, and the following phenomena have been investigated: inlet/forebody interference at low incidence; inlet/ground interference at take off conditions; and inlet/airframe interference. All the above mentioned studies are based on flow visualizations in water tunnel, merged with theoretical studies, semiempirical, and handbook methods. Author

A small rig has been designed and made to study fountain flows formed by subsonic jets impinging onto a ground plane. A series of tests was carried out to investigate three dimensional flow patterns and pressure distributions in the fountain flows. A program of tests was then devised to establish fountain flow pressures and normal forces on rectangular blocking trays of various designs. Most tests were carried out at ambient temperature but some tests were carried out with pre-heated compressed air. The effect of the distance between the jets and the trays from the ground plane was examined and recorded. Moving ground board tests were also performed. Author

A brief review of the work accomplished by the numerical subgroup of AGARD Working Group 13 on the aerodynamics of high speed air intakes is presented. This work comprised the selection of test cases for which experimental data were available. The test cases were chosen to range in complexity from normal-shock/boundary-layer interaction to full forebody-inlet combinations. Computations for these test cases were solicited from a large number of organizations and individual researchers within the NATO countries. The computation methods reached from Euler solvers (with and without boundary layer corrections) to full Reynolds averaged Navier-Stokes codes. The group compared these results with the test data available for each test case. A short overview of the CFD methods employed, a description of the test cases selected, and some of the comparisons between CFD solutions and test data are presented. The conclusions and recommendations drawn from this assessment are given. Author

A computational fluid dynamics (CFD) method is presented for the analysis of complex two-dimensional (2D) geometries using unstructured grid techniques. The grid generation procedure uses

a split tree technique for subdividing the domain and generating internal mesh points. A Delaunay triangulation method is employed to triangulate the points, then iteratively refines the mesh based on cell aspect ratios and area variation to improve the quality of the initial mesh. The full Navier-Stokes equations are solved using an upwind flux difference splitting scheme for the inviscid flux and a central differencing scheme for the viscous flux. A two equation turbulence model is included for analyzing turbulent flows. A Jacobi iteration procedure is used to solve the linear set of implicit equations at each time step. Two 2D propulsive flowfields are analyzed and compared with experimental data. The grids are adapted to the flowfield by refinement based on the flowfield gradients. Improved resolution of the pertinent flowfield features were a result of the grid adaption employed. Author

The current trend in fighter aircraft design is toward highly integrated propulsive exhaust systems. In order to achieve this level of integration, extensive testing and analysis is required. Modern computational fluid dynamics (CFD) techniques have become popular in performing a part of the required analyses. Because of the complexity of most nozzle/afterbody type flow fields, Navier-Stokes codes are generally the preferred CFD methods. To gain confidence in these solvers ability to provide useful design information, a number of calibration analyses must be conducted. Extensive test data are available for these comparisons. This paper describes three such analyses which were used to calibrate two Navier-Stokes codes. The first case deals with the internal flow through a vectored nozzle. The second case looks at the development of an exhaust plume issuing from a rectangular nozzle. The third case considers the flow over an afterbody with a high-aspect-ratio rectangular nozzle. In all cases, both qualitative and quantitative comparisons are made between the test data and the CFD data. Good comparisons are obtained and additional confidence is gained in these CFD codes ability to provide useful engineering data. Author

INVESTIGATION OF THE FLOWFIELD AROUND AN ISOLATED BYPASS ENGINE WITH FAN AND CORE JET
R. RUDNIK, A. RONZHEIMER, C.-C. ROSSOW, and H. HOHEISEL *In* AGARD, Aerodynamic Engine/Airframe Integration for High Performance Aircraft and Missiles 8 p (SEE N93-13199 03-34) Sep. 1992
(AGARD-CP-498) Copyright Avail: CASI HC A02/MF A04

A finite-volume scheme for the discretization of the three-dimensional Euler equations is extended for the purpose of calculating the flowfield around an isolated bypass engine with fan- and core-jet. Flow calculations for a typical high bypass engine are performed for take-off and cruise conditions under consideration of realistic operational jet parameters. Several variations of the jet pressure and temperature ratio show that the jet flowfield is dominated by the pressure ratio as far as inviscid flow is concerned. A comparison of the numerical results to experimental investigations, which are carried out with a turbine powered simulator for low speeds, exhibits good agreement. The influence of numerical parameters on the solution in the region of the jet flow is analyzed by varying the coefficients of the artificial dissipation. Author

The feasibility of air breathing propulsion for future space launch vehicles largely depends on the possibility of designing air intakes that will give the best trade-off between internal performance and which will provide suitable air supply to the engine, weight reduction, and aerodynamic drag. The trade-off can be markedly improved by using air intake designs with variable absorption sections. The design concepts are defined and their application to space launch vehicles is analyzed with respect to internal performance, mass, and aerodynamic drag. Transl. by L.B.

The accurate prediction of turbine heat transfer remains beyond our current capabilities. To investigate this condition, nonconventional turbulence generation techniques have been employed to explore the impact of high turbulence or unsteadiness on heat transfer. The heat transfer from a 2D planar wall jet is compared with an axisymmetric wall jet with twice the turbulence scale and more turbulent kinetic energy - with an increased heat transfer shown by the planar configuration. The resulting comparisons of wall jet augmented heat transfer to engine turbine blade heat transfer is quite favorable. Derived from text

Turbulence in turbine flows of gas turbine engines is generally inhomogeneous and is also characterized by wide ranges of intensity and scale. The interaction between Free Stream Turbulence (FST) and boundary layer turbulence (BLT) is complicated in all but the case of low values of both intensity and scale. In a recent investigation, an attempt was made to establish the effect of homogeneous FST on wall friction (when there is no heat transfer) in the relatively simple case of a flat plate, zero pressure gradient boundary layer. In the current paper, the method was extended for the prediction of heat transfer in the same flow field. In any problem involving heat and momentum transport, it is common to introduce some type of similarity between the two transport processes. The current method is based on the application of a similarity rule governing the spectra of turbulence intensity and temperature variance. The principal outcome is a method of establishing heat transfer in a given flow field for which experimental data are available under cold flow conditions and have been verified with the model prediction scheme.

This paper presents the results of an experimental program aimed at investigating the effect of Coriolis forces and centripetal buoyancy on forced convection in an internally finned circular tube which rotates about an axis orthogonal to the tube's central axis. This geometric arrangement typifies the internal coolant channels of gas turbine rotor blades. It is demonstrated that, as with smooth-walled tubes, Coriolis-driven secondary flows give rise to relatively better heat transfer on the trailing edge of the tube compared with that on the leading edge. Leading edge heat transfer is shown to be significantly impaired in relation to that which occurs under non-rotating conditions. Centripetal buoyancy is shown to improve local heat transfer on the leading and trailing edges for a given value of the through flow Reynolds number and the Rossby number. Although duct rotation tends to improve heat transfer on the trailing edge in comparison with normal stationary duct forced convection, serious overprediction of heat transfer results from ignoring rotational effects on the leading edge. This is an important observation in the context of the design of turbine rotor blade cooling systems. Author (revised)

Measurements were made of the local heat transfer at the surface of a flat plate underneath a confined impinging jet. Thermochromic liquid crystals were used to measure the surface temperature of a uniformly heated plate cooled by an impinging jet. The temperature of the wall through which the jet passes was controlled, and experiments were performed to measure the two heat transfer coefficients which arise from this three temperature problem. The effect of Reynolds number and plate to jet spacing on heat transfer was investigated. The heat transfer results are discussed in terms of the interpreted flow field. Author (revised)

A control volume, finite difference method based on the work of Rhie in conjunction with a high Reynolds k-epsilon model and a two layer turbulence model was used to predict the heat transfer coefficients underneath an impinging circular jet in the absence of cross flow. The numerical results are compared to experimental measurements for two different impingement height to jet diameter ratios: H/D = 2, and H/D = 10. The comparisons indicate that, although both the k-epsilon and the two layer turbulence models are adequate in the prediction of the flow field, the two layer model resulted in heat transfer predictions that were closer to experimental observations. It was also observed that the predicted heat transfer coefficients for the case of H/D = 2 were sensitive to the assumed jet exit turbulence levels, whereas they were not for H/D = 10. This information is useful to the designer of cooled turbine components. Author (revised)

The Swollen Polymer Technique is a mass transfer analogy method for obtaining heat transfer data. It is similar in principle to the naphthalene method, but it has an advantage in that it can be combined with interferometric measuring methods giving a panoramic view of the distribution of the transfer coefficient over the working surface. Additionally, the mass transfer process is reversible, and the working surface can be used repeatedly. Changes in thickness of a polymer coating on the working surface, initially swollen with an ester, are measured, using holographic interferometry to yield a fringe pattern depicting loci of equal transfer coefficient over the surface. The paper describes the basis of the method, the equipment required to implement it, the precautions necessary for its successful use, its advantages, its limitations, and its future potential. The technique yields data useful in the design process. Examples of its application to film cooled surfaces are given, including the effects of geometry, density ratio, and acceleration of the mainstream flow on the heat transfer coefficient. Extension of the technique for the simultaneous measurement of effectiveness and heat transfer coefficient is described, and its further extension for use with curved surfaces is outlined. A recent development to the technique itself by the use of a thermoplastic plate for recording the holograms opens up the possibility of further advancement using electronic image processing. The flow regimes in rotating cavities (modelling corotating disks or rotor-stator systems), with or without through flow, are studied by numerical approach using different techniques: spectral and finite volume methods. Comparisons between these techniques have been carried out for a typical test case. The solutions have been also compared satisfactorily to asymptotical approximations and to experimental results. The computations with spectral methods have been carried out until the onset of unsteady instabilities and transition to turbulence. The turbulent regimes have been treated with the finite volume method based on modelling derived from a k-epsilon or algebraic model of second order. Author (revised)

FLUID FLOW AND HEAT TRANSFER IN THE ENTRANCE REGION OF AN ANNULUS BETWEEN INDEPENDENTLY ROTATING TUBES WITH A TURBULENT AXIAL FLOW

H. PFITZER, T. ROTHE, and H. BEER *In* AGARD, Heat Transfer and Cooling in Gas Turbines 11 p (SEE N93-29926 11-07) Feb. 1993

(AGARD-CP-527) Copyright Avail: CASI HC A03/MF A04

Experimental and numerical investigations of turbulent flow and heat transfer have been performed in the entrance region of a concentric annulus between independently rotating tubes. The horizontally mounted test section has an electrically heated outer wall and an adiabatic inner wall. The mean heat transfer rate in the hydrodynamic and thermal entrance region as well as the local Nusselt number at the axial position z/db(sub h) approx. = 60, which is the end of the rotating annular channel, were determined experimentally. Hotwire and thermocouple probes

allowed for measurement of velocity and temperature distributions at the end of the annulus. Numerical predictions, applying a k-epsilon eddy viscosity model with a modification by the flux Richardson number, are compared with the experimental results. The comparison shows that general effects of the rotation can be predicted quite well with the aid of a simple turbulence model. Due to stabilizing or destabilizing effects of centrifugal forces in the fluid and due to the additional shear stress, the rotation of the inner and the outer tube influences remarkably fluid flow and heat transfer in the annulus. THE EFFECT OF MAIN STREAM FLOW ANGLE ON FLAME TUBE FILM COOLING
H. KLINGER and D. K. HENNECKE *In* AGARD, Heat Transfer and Cooling in Gas Turbines 12 p (SEE N93-29926 11-07) Feb. 1993 Sponsored in part by BMFT

Generally film cooling configurations are positioned such that they are oriented perpendicular to the main stream flow direction. However in many cases, in particular combustor applications, different flow angles may occur. Then, due to the interaction between the main stream and the cooling film, a complex three-dimensional flow field with a vortex is formed. An experimental study was done to study the basic effects. The cooling configuration was a vertical slot which could be turned by up to about 60 degrees from the position perpendicular to the main stream. Velocity distributions were measured and the adiabatic film cooling effectiveness was determined using the liquid crystal technique. The results show that, along lines parallel to the slot, the film cooling effectiveness varies strongly, even with small slot turning angles. This would lead to hot and cold spots in a combustor application. A simple semi-empirical correlation for the average cooling effectiveness is derived using the main stream velocity component perpendicular to the slot. Author

(AGARD-CP-527) Copyright Avail: CASI HC A02/MF A04

Impingement/effusion cooling offers one of the most effective ways of cooling gas turbine combustor walls and turbine blades. The design principles are reviewed and cooling effectiveness data presented for a range of typical geometries with holes at 90 degrees to the surface. The main variable studied was the number of impingement/effusion holes. Comparison was made with the effusion cooling effectiveness. Optimum configurations were demonstrated with a 0.7 overall cooling effectiveness at a mass flow per unit surface area of 0.2 kg/sm(exp 2)bar. This was equivalent to 10 percent of the combustor air flow for a typical gas turbine combustor. Data is also presented for the overall wall heat transfer coefficient. The mechanism of the enhanced heat transfer within the impingement/effusion double skin wall was investigated using a CFD code. This predicted the complex aerodynamics in the impingement gap and also gave good agreement with the measured overall heat transfer data.

Four flux-type models for radiative heat transfer in cylindrical configurations were applied to the prediction of radiative flux density and source term of a cylindrical enclosure problem based on data reported previously on a pilot-scale experimental combustor with steep temperature gradients. The models, which are Schuster-Hamaker type four-flux model derived by Lockwood and Spalding, two Schuster-Schwarzschild type four-flux models derived by Siddall and Selcuk and Richter and Quack and spherical harmonics approximation, were evaluated from the viewpoint of predictive accuracy by comparing their predictions with exact solutions produced previously. The comparisons showed that spherical harmonics approximation produces more accurate results than the other models with respect to the radiative energy source term and that the four-flux models of Lockwood and Spalding and Siddall and Selcuk for isotropic radiation field are more accurate with respect to the prediction of radiative flux density to the side wall. The progress which was recently achieved in the modeling of turbulent combustion for applications to propulsion are described. The averaged equations of reactive turbulent flows are given, then the Probabilist EUlerian Langrangian model (PEUL) intended for the calculation of the average source terms of categories and of enthalpy are presented. The possibility of taking into account by this model the reactional mechanisms to several categories is applied to the prediction of the pollutants and in particular to the calculation of thermal NO. In order to obtain the best possible prediction of the chemical composition and the temperature, three total mechanisms of oxidation of methane are successively coupled with the PEUL model and their results compared. Two applications are then studied. The first application is a premixed flame stabilized by a hot gas flow. The computation results are compared with the experimental results obtained with ONERA and present a suitable agreement, in particular with regard to the profiles of thermal NO. The second concerns a portion of an annular aeronautical chamber. The comparison of the average production rates obtained with a model of turbulent combustion with rapid chemistry and with the PEUL model highlights, in this case, the importance of not making the hypothesis of rapid chemistry.

Different aerodynamic aspects of the flow field generated when a single jet or a row of jets are ejected into a mainstream are experimentally investigated. The similarity parameters are taken such as to match those of the three-dimensional film cooling. The objective is to deepen the understanding of the complex phenomena associated with these flows, and to provide a comprehensible and detailed data base for validation of numerical codes. To be able to obtain high resolution measurements, the study is made on large scale models. The scale enlargement obliges to use moderate velocities, so that the Reynolds number can be kept within realistic limits and the similarity preserved. The use of low air speeds prevents the analysis of compressibility effects. This restriction is not as severe as one can think because, according to the related bibliography, these effects start to be noticeable at Mach numbers higher than 0.8, while the designers avoid to inject the coolant in the vicinity of shock waves to avoid boundary layer separation. The study is made on three different models installed in a low speed wind tunnel. A first model consists of a flat plate with a single inclined circular hole. The isolated jet/mainstream interaction is investigated by means of this first test plate. The other two models present the same configuration as the first but having now a row of holes with different pitch to diameter ratios in each case. These models are useful to understand the interaction between jets and to analyze the formation and development of the coolant layer.

(AGARD-CP-514) Copyright Avail: CASI HC A03/MF A04

Accurate predictions of the effects of shock wave turbulent boundary layer interactions are of particular importance in the design of hypersonic vehicles. Such flows can generate intense heat transfer rates and pressure levels, complex large-scale unsteady separated flows, and large-amplitude fluctuating loads. With increased reliance on computation, it is critical that the predictions are accurate. Thus, it is imperative that such codes be validated and calibrated and deficiencies be identified and rectified. Comparison of the predictions of computational fluid dynamics (CFD) codes with experimental data is the key element of the validation process. However, drawing meaningful conclusions about the strengths and weaknesses of solution methodologies or of turbulence models from these comparisons is not a trivial task. As recently stated by Jameson, 'Simply comparing experimental data with numerical results provides no way to distinguish the source of the discrepancies, whether they are due to faulty numerical approximation or programming, or to deviations between the math model and true physics.' The conclusions drawn may be quite misleading if it is not clearly understood what the computations represent and what the experimental data represent. This paper discusses why it is important to know how experimental mean flowfield and surface data being used for comparison with CFD are generated. If the flowfields exhibit local or global large-scale unsteadiness, then such mean measurements, which form the bulk of the existing data base, may mask the underlying flow physics and be inappropriate for comparison with computation. This paper gives a survey of theoretical and experimental results related to the problem of boundary layer transition; emphasis is given on applications of practical prediction methods. In the first part of the paper, it is shown that the linear stability theory can provide a good estimate of the transition location if the free stream disturbance level is low enough; the difficulties to properly simulate free flight conditions in ground facilities is underlined. The second part of the paper is devoted to the problem of boundary layer tripping in the presence of large external disturbances; in this case, the linear theory no longer applies and empirical criteria need to be developed. Considerable advances have been achieved over the last decennia in the field of cascade testing, but they were generally not reported in sufficient detail. As an example, details of transonic/supersonic cascade testing procedures were scarcely documented in literature. Many other aspects evolved considerably, originally from the progress of experimental techniques as well as from the interaction with computer data. New methodologies based on advanced instrumentation gained sufficient validation. Consequently, the Propulsion and Energetics Panel decided to initiate an AGARDograph on this subject in 1988. Since then, several authors prepared chapters for the AGARDograph, coordinated by the editor. The following chapters are included: Modeling Turbomachinery Flow Conditions, Linear Cascades, Annular Cascades, Aspects of Hot Cascades, Transient Cascade Testing, Unsteady Flow in Cascades, and 3-D Laser Anemometry in Annular Cascades. Notes for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Shock-Wave/Boundary-Layer Interactions in Supersonic and Hypersonic Flows' are presented. The objective was to report on results from recent research programs providing a consolidated review of these activities and a sound basis for developing more reliable methodologies for future vehicle design. The course also provided a focused review of recent progress for swept interactions in both laminar and turbulent flows, including discussions: flowfield structure; scaling and similarity laws; effect of shock strength on flow feature; effect of shock generator geometry for a given shock strength; techniques for investigating swept interactions, particularly optical techniques; and contributions of numerical simulations to the understanding of swept interactions. The effects of turbulence and turbulence modeling on the flowfields are provided. For individual titles, see N94-15197 through N94-15203.

A general review is given of several decades of research on the scaling laws and flowfield structures of swept shock wave/turbulent boundary layer interactions. Attention is further restricted to the experimental study and physical understanding of the steady-state aspects of these flows. The interaction produced

by a sharp, upright fin mounted on a flat plate is taken as an archetype. An overall framework of quasiconical symmetry describing such interactions is first developed. Boundary-layer separation, the interaction footprint, Mach number scaling, and Reynolds number scaling are then considered, followed by a discussion of the quasiconical similarity of interactions produced by geometrically-dissimilar shock generators. The detailed structure of these interaction flowfields is next reviewed, and is illustrated by both qualitative visualizations and quantitative flow images in the quasiconical framework. Finally, the experimental techniques used to investigate such flows are reviewed, with emphasis on modern non-intrusive optical flow diagnostics. Author

Experimental and numerical investigations of swept shock wave/laminar boundary layer interactions are reviewed. Experimental investigations show that the flowfield is characterized by an extensive primary separation of the boundary layer upstream of the inviscid shock wave, which then rolls up into a very elongated vortex. This is often accompanied by secondary and sometimes higher order separations. Similar to turbulent interactions, the flowfield is essentially conical as far as the surface flow data are concerned (surface pressures, heat transfer, and skin friction patterns). Also, the free-interaction concept introduced for turbulent interactions is shown to apply to laminar interactions as well. Recent LDV flowfield data for a supersonic interaction are presented. They nicely confirm the vortical structure of the interaction deduced from the surface data as well as the important thickening of the viscous layer due to separation. They also show that the vertical dimension of the interaction does not obey a conical similarity rule but rather follows the classical boundary layer scaling. Numerical investigations confirm these experimental findings. None of these was however carried out with sufficient grid resolution so as to demonstrate grid convergence and code validity, in particular concerning the location of separation lines. The capability for numerical simulation of 3-D shock wave turbulent boundary layer interactions is assessed. Specific configurations examined include the sharp fin, blunt fin, cylinder/flare, swept compression corner and crossing shock. Future needs in improved computational methods, collaborative experimental/computational efforts and incorporation of knowledge of flowfield structure into more effective designs are discussed. A brief review is given of the unsteadiness of shock wave/turbulent boundary layer interaction. The focus is on interactions generated by swept and unswept compression ramps, by flares, steps and incident shock waves, by cylinders and blunt fins, and by glancing shock waves. The effects of Mach number, Reynolds number, and separated flow scale are discussed as are the physical causes of the unsteadiness. The implications that the unsteadiness has for interpreting time-average surface and flowfield data, and for comparisons of such experimental data with computation, is also briefly discussed. Finally, some suggestions for future work are given. It is clear that there are large gaps in the data base and that many aspects of such phenomena are poorly understood. Much work remains to be done. Author

With the advent of Laser Doppler Velocimetry (LDV) in the 1970's, it became possible to investigate high speed complex flows containing shock waves, separated regions, and strong turbulent fluctuations. This powerful tool has allowed an unprecedented physical description of the flow fields resulting from shock wave/boundary layer interaction, both in two- and three-dimensional flows. It is remarkable that the development of LDV accompanied the progress in CFD, thus permitting an in depth validation of the theoretical models. The Lecture focusses on the use of LDV to investigate typical transonic and supersonic interactions occurring, firstly in nominally 2D configurations, then in a 3D channel flow. The data thus obtained are used to validate a detailed description of the flow field and to validate several equilibrium and non-equilibrium turbulence models. In 2D flows, the calculations were executed by using an economical boundary layer type approach, for the 3D case the models were implemented in a Navier-Stokes code. Author (revised)

Since the pioneering theory of Boussinesq and the first application indicated by Prandtl, turbulence modeling has been continuously improved in order to allow effective prediction of turbulent flows. Since these early contributions, various methodologies were worked out to account properly for 'complex' effects on turbulence. Among others, these 'complex' effects are caused by curvature, body forces (gravitation or magnetic fields), unsteadiness, and variable density. In fact, in real flows situations, it is often difficult to separate these effects, and the prediction of a flow configuration of industrial interest must always combine the simultaneous treatment of several effects. Depending on the application domain, some effects can be considered as dominant which allows neglect of others completely. As an example, geophysical flows in oceans are dominated by stratification and rotation, while compressibility or solid boundary effects can be neglected. In contrast, flows around an aircraft fuselage in real flight conditions are strongly influenced by compressibility and wall effects and not at all by gravitation or rotation. Because of the requirements imposed by a wide variety of industrial and aeronautical problems, one of the biggest challenges, during the last few years in the field of turbulence modeling was the correct accountability of the variable density effects. Variable density can have different origins, which can result for instance from: (1) the mixture of gases with different density; (2) a temperature gradient within an homogeneous fluid; (3) compressibility in high speed flows; or (4) reactive flows (for instance flames, chemical or gasdynamic laser flows). Unfortunately, until now, only a small fraction of the modeling effort has been devoted to these flows. Author

The problem of hypersonic shock wave boundary layer interactions over simplified geometric configurations that simulate the vicinity of deflected control surfaces on lifting reentry vehicles is addressed. The discussion evolves primarily around surface pressure and heat transfer data over flat plate/two-dimensional and swept compression ramp configurations, and the axisymmetric hyperboloid/flare configuration, emphasizing the prediction of peak heating in regions of interaction, the promotion of laminar-turbulent transition, and the performance and validation of CFD codes. Following a brief overview of the fundamental physical phenomena associated with shock wave boundary layer interactions, as these have been identified and summarized in the extensive literature available on the subject, the paper is split into three main parts. The first part concentrates on the analysis of global pressure and heat transfer distributions and their comparison with simple boundary layer theory, emphasizing peak heating at the downstream end of the interaction region. The second part addresses the formation of streamwise striations in reattaching flow regions, and the associated spanwise heat transfer variations which may exceed plus or minus 50 percent of the mean local heating level. Last but not least, the performance and limitations of state-of-the-art Navier-Stokes computations in computing hypersonic separated flows are illustrated by means of a series of computational fluid dynamics (CFD) code validation test cases assembled in recent years. The 37 papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium on Computational and Experimental Assessment of Jets in Cross Flow are included. The primary objective of the Symposium was to provide a forum for assessing advances made in the technology and application of jets in cross flow which have occurred since the last meeting on this subject. Major topics covered included enhanced descriptions of the fundamental flow structure of jets in cross flow, experimental methods, thrust vectoring, jet impingement and exhaust gas reingestion, hypersonic crossflow, and numerics and turbulence modeling. For individual titles, see N94-28004 through N94-28040.

The jet in cross flow (JICF) is a basic flowfield which is relevant to a wide variety of applications which are described to provide context for JICF investigations. Material consistent with the scope of topics presented at the 72nd AGARD Fluid Dynamics Panel Meeting and Symposium on Computational and Experimental Assessment of Jets in Cross Flow on 19-22 April 1993 in Winchester, U.K. is summarized. The JICF research was divided into three time periods: (1) early research - up to 1970, (2) research during the 1970's, and (3) research since 1980. The following areas of experimental activity are discussed; the definition of an effective correlation parameter; the jet flowfield including the jet trajectories, cross-section shape, and jet induced pressures; the effects of jet deflection angle, nozzle shape, pressure ratio, velocity decay, and temperature; and the effect of confined flowfield, ground effects, multiple jets, and adjacent surface geometry. In addition, computational methods are discussed including both potential flow based methods, some with empirical and semi-analytical extensions, and Navier-Stokes based computational fluid dynamics (CFD) investigations. Currently modern CFD methods have been able to compute many of the mean flow characteristics of the JICF. Existing CFD methods have not resolved the separated flow region in the near wake of the jet exit. There is also a need for high quality, extensive experimental data which will enable the verification of current and future CFD results and to define unsteady flow characteristics. Author (revised)

(AGARD-CP-534) Copyright Avail: CASI HC A03/MF A04

The transient features of a supersonic jet exhausting into a low speed cross flow were studied experimentally. The experiments were conducted in the Southampton University's 3.5 m x 2.6 m low speed wind tunnel. Three supersonic jets at ambient temperatures were used, one being a convergent nozzle and the other two being convergent-divergent nozzles having respectively design Mach numbers, M(sub d) = 1.4 and 1.7. Each jet issued in the normal direction to a flat plate mounted at zero incidence in the center of the wind tunnel. The jet pressure ratio varied between 1.2 and 5.0 and the cross flow velocity between 14m/s and 38m/s. Both over-expanded and under-expanded jets were used. The low speed cross flow was found to introduce complex multiple narrow band tones. Changes in the transient flow modes and the levels of the tones were observed from time resolved pressure measurements at various positions on the flat plate.

The unsteady vortex structures in the wake of a transverse jet were studied using a new laser scanning apparatus to obtain three-dimensional images of fluorescent dyes in a water channel flow. By scanning the laser at high repetition rates and by using a high-speed video camera to record the images, the three-dimensional, time-evolving concentration field in the wake can be obtained and later reconstructed. Using this system, the separation and roll-up of the flat plate boundary layer and the subsequent convection of that vorticity away from the wall can be visualized. The relationship between the separation and roll-up on the other side of the wake can also be studied. On the basis of the reconstructed concentration fields, an attempt is made to describe the mechanisms of wake vortex formation and explain the results of some previous authors. Author

Results of an experimental investigation to determine the characteristics of the separated flow region generated by a subsonic vectored rectangular jet in a subsonic crossflow is presented. Using surface visualization techniques, it was found that the upstream separated flow consist of horseshoe vortices that are formed periodically with a frequency corresponding to that of the vortex shedding behind the jet. The size of the recirculation region around the jet is found to decrease with increasing jet vector angle. The variation of the mean primary separation distance upstream of the jet, with velocity ratio revealed the existence of two different flow regimes. The change from one to the other depends on the velocity ratio and the jet vector angle. It is shown that the Strouhal number, based on the vortex shedding frequency and a combination of jet exit and freestream velocities, varies uniquely with velocity ratio. Author

SCALAR MIXING IN THE SUBSONIC JET IN CROSSFLOW

S. H. SMITH, A. LOZANO, M. G. MUNGAL, and R. K. HANSON *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow 13 p (SEE N94-28003 07-34) Nov. 1993 Sponsored by AFOSR

(AGARD-CP-534) Copyright Avail: CASI HC A03/MF A04

Results are presented on the structure and mixing of subsonic jets in crossflow. These results are obtained by using planar laser-induced fluorescence of acetone vapor which is carried as a marker of the jet fluid. In addition to providing instantaneous realizations of the jet structure, the data is quantitative in providing instantaneous measures of the jet mixture fraction. Jet to crossflow velocity ratios ranging from 6 to 14, corresponding to momentum ratios of 36 to 196 were examined. It is found that the instantaneous structure is quite complex, dominated by large-scale motions, and bear little resemblance to ensemble-averaged field. Jet fluid is seen in the wake structure in the curved portion of the jet, even though the amounts are small. Mean and rms concentration fluctuations are presented for select cases. Author (revised)

THE INTERACTION REGION ASSOCIATED WITH TWIN JETS AND A NORMAL CROSSFLOW

N. TOY, E. SAVORY, S. MCCUSKER, and P. J. DISIMILE (Cincinnati Univ., OH.) *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow 11 p (SEE N94-28003 07-34) Nov. 1993

(AGARD-CP-534) Copyright Avail: CASI HC A03/MF A04

An experimental investigation of the interaction between twin jets and a normal crossflow using real-time, quantitative, video image analysis of smoke-seeded jets to yield information concerning overall jet growth rates, the widths of the interface regions, intermittencies, p.d.f.s, and spectra of the interface fluctuations is presented. The cases covered are side-by-side and in-line jets, with a nozzle spacing of 5 nozzle exit diameters and a jet velocity/crossflow velocity ratio of 8, together with the single jet cases. Additional data, in the form of velocity vector distributions from five-hole pressure probe measurements, were obtained for comparison with the intermittency profiles in planes across the jets for the case of side-by-side jets with a nozzle spacing of 5 diameters and a ratio of 6. Finally, a parametric study of the effect on the overall jet penetration of velocity ratio (from 4 to 10), nozzle spacing (from 1 to 5 diameters) and nozzle orientation to the crossflow (from in-line to side-by-side, but with normal injection angle) was carried out using a new digital image processing system. The velocity data for the side-by-side case shows that the deflected jets are dominated by one single vortex pair such that the inner vortex of each jet pair are not evident. The video analysis of the three main configurations, side-by-side, in-line and single jet, shows that in all cases the width of the mixing region at any downstream location is similar in magnitude to the jet half-width (as defined by the mean interface location). The interface widths are similar for the side-by-side and in-line jets but these are greater than the single jet for the intermittency distributions across the interface regions which will enable correlation between the different jet configurations. The parametric study shows that, for a given jet ratio, the in-line jets (0 deg angle) penetrate further than those set at other angles to the crossflow and that changes of angle between 30 deg and 60 deg have less effect upon the overall penetration. For the in-line case it is the second jet, issuing into the lower static pressure region downstream of the first jet, that penetrates furthest into the crossflow. Author

EXPERIMENTAL DATA FOR CFD VALIDATION OF IMPINGING JETS IN CROSSFLOW WITH APPLICATION TO ASTOVL FLOW PROBLEMS

P. BEHROUZI and J. J. MCGUIRK *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow 11 p (SEE N94-28003 07-34) Nov. 1993 Sponsored by British Aerospace Public Ltd. Co.

(AGARD-CP-534) Copyright Avail: CASI HC A03/MF A04

An experimental facility, used to gather validation data suitable for testing CFD model predictions of multijet ground impingement flows, is described. Water is used as the working medium and LDV measurements of twin impinging jets are reported, both with and without a cross-flowing stream. Emphasis is placed on the presentation of mean and rms velocity contours in the foundation formation region between the jets. The effect of jet splay angle has also been studied. For zero splay or 10 deg of splay-out, the fountain is observed to develop as an upwash flow spatially separated from the two jet flows (jet spacing at six jet diameters); for 10 deg splay-in, a noticeable fountain/jet interaction is observed. Splay-out reduces the strength of the fountain by around 50 percent whereas splay-in has an opposite, strengthening effect for the seven jet diameter impingement height studied here. The effect of a cross-flow (jet/cross-flow velocity ratio of 10) leads to a clear downwind shift of the fountain origin and inclination of the fountain rise. The results presented offer a sufficiently comprehensive mapping of the mean velocity and turbulence fields to form suitable test cases for the validation of CFD models for ground effect flows. EXPERIMENTAL INVESTIGATION OF THE INTERACTION OF A THRUST REVERSER JET WITH AN EXTERNAL SUBSONIC FLOW

J.-M. CHARBONNIER, K. DECKERS, and G. WENS *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow 10 p (SEE N94-28003 07-34) Nov. 1993

(AGARD-CP-534) Copyright Avail: CASI HC A02/MF A04

An experimental modelization of a door-type thrust reverser is conducted in a subsonic wind tunnel. The geometry of the model is defined in order to simulate both the internal and external flow of a real thrust reverser. Different door configurations are studied for a selected value of the mass flux injection ratio of three. Visualizations illustrate qualitatively the jet interaction, and extensive mean velocity and pressure measurements are conducted in sections perpendicular to the upstream flow direction with a five hole probe. The total pressure losses and the drag force produced by the thrust reverser are deduced from the measurements. As a result, it shows that the smaller opening angle of the door (56 deg), with a becquet deflection of 15 deg gives the larger drag force. In addition to the classical pair of counter rotating vortices observed in jet in cross flow interactions, a second pair of counter rotating vortices below the main pair is found. The vorticity field is described with good agreement by a simple vortex model simulating the two pairs of vortices. Author (revised)

The prediction of vectored jet-induced effects on V/STOL configurations during transition phase and maneuvers constitutes an important aspect in the understanding, design, control, and operation of such aircraft. In this paper, a semiempirical modelling of the jet is used within the framework of subsonic singularity methods. Comparisons with experimental data on a wing-body configuration have been presented. In general, acceptable agreement has been demonstrated. Overall, the emphasis has been on predicting jet interference effects on practical configurations with multijet effects and forward and aft nozzles. Configuration effects include tails which operate in a much stronger jet downwash than the wing. Optimization studies can be enabled prior to experimental programs. This process will allow the design cycle to commence with a good idea of the relative effectiveness of the various controls and the changes needed in the flight control system to cope with partially jet-borne phases of flight. Therefore there is a significant potential for encouraging cost and time savings. Areas for further work and improvements of the model have been proposed. It is believed that these aspects will have a constructive impact on current and future practical VSTOL and ASTOVL developments. Author (revised)

Injection of secondary air into nozzle flows is an efficient method to control the thrust vector angle of an aircraft. A numerical investigation of thrust vectoring has been carried out for hypersonic aircraft in the transonic flight regime. In this speed range, single duct asymmetrical single expansion ramp nozzles operate far off design due to large nozzle exit areas required for optimal thrust coefficients at hypersonic cruise Mach numbers, thus producing large thrust components in the downward direction. Injecting secondary air into the nozzle flow in the critical transonic flight Mach number regime can lead to favorable gross thrust vector angles and thus improved thrust efficiency in flight direction. For a hypersonic aircraft's rectangular convergent-divergent nozzle configuration with a single expansion ramp, two dimensional Euler calculations of the complete afterbody flow field were carried out in the transonic flight regime, investigating subsonic as well as supersonic injection of the aircraft's forebody boundary layer air into the nozzle flow. Subsonic flow of the injected air along the expansion ramp produces a favorable pressure distribution on the ramp and results in advantageous thrust vectors with small force components normal to the flight direction and in best thrust efficiency. The interaction between the external flow, the jet plume flow, and the secondary air flow, as well as the behavior of the thrust vector, due to pressure and temperature variations of the injected forebody boundary layer air, are discussed. Also investigated was the impact of the aircraft's angle of attack on the complete nozzle flow field. Author (revised)

Experimental studies of round jets in cross flow have been made using flying hot-wire and flow visualization techniques. The velocity ratio of the flow ranged from about two to six with the Reynolds number up to 6200. The flying hot wire enables time- and phase-averaged measurements to be made in regions of the flow which cannot be measured accurately using stationary wires. These quantitative results together with the complementary flow visualization studies have allowed the mean topological features of the jet in cross flow to be identified using critical point theory. An understanding of these flow features may provide insight into the large-scale mixing processes which occur in the shear layer of the jet. Author (revised)

Experiments were conducted in a laboratory flume to study the interaction of bivalve siphonal jets with the turbulent boundary layer which forms in the benthic region of shallow estuaries. Beds of siphonate bivalves (clams) 1.8 meters long were simulated to study the formation of a phytoplankton-depleted layer (concentration boundary layer) over bivalves. Refiltration of excurrent fluid through incurrent siphons, which represents a decrease in aggregate feeding efficiency, was measured for two test beds with S/d(sub o) = 6 and 16 and siphon pairs oriented perpendicular to the cross flow direction. Results are expressed as a function of the nondimensional distance downstream, x/d(sub o), the velocity ratio, VR=u(sub j)/U(sub infinity), and the nondimensional animal spacing, S/d(sub o). Laser induced fluorescence was used to obtain quantitative concentration profiles in order to describe the evolution of the flow and to identify parameters that describe the jet/boundary layer interaction. An inclined jet impinging on the ground creates a wall flow that spreads radially from the point of impingement. If a cross-flow is introduced, the upstream component of the wall flow will separate from the ground and create what has been termed the 'ground vortex.' The ground vortex has been shown to have a significant impact on aircraft aerodynamics and is one of the major contributors to hot gas ingestion. The paper discusses a recent study which included a generic wing-body configuration for assessing the impact of the ground vortex on configuration aerodynamics. Wind tunnel tests using fixed ground boards, moving ground belts, and moving model tests are discussed. The emphasis of the data is macroscopic, i.e. forward location of the vortex, effects of ground height, etc. Author (revised)

The flowfield induced by a single, subsonic jet exhausting perpendicularly from a flat plate into a subsonic crossflow has been numerically investigated. The test case was chosen to match available experimental data where the jet Mach number was 0.78, and the freestream Mach number was 0.13. Time-averaged solutions were obtained using the thin-layer Navier-Stokes equations and two overlapping grids. The solutions were sensitive to the radial grid clustering near the edge of the jet and to the far-field boundary conditions. Experimental data comparisons were

required to determine the most appropriate jet grid and satisfactory boundary conditions. Globally, the solutions converged in about 6000 iterations. The computational results accurately showed the deflected jet and associated contrarotating vortices. The fine clustered grid in the region upstream of the jet exit allowed the horseshoe vortex in the boundary layer near the jet exit to be captured. Most importantly for aircraft applications, the computed plate pressure distributions compared favorably with the experimental data over most of the surface. However, in the wake region immediately downstream of the jet exit, where there is extensive flow separation, some discrepancies with experimental data were observed. Two turbulence models were used in this study: (1) the zero-equation, two layer Baldwin-Lomax turbulence model; and (2) one-equation Baldwin-Barth turbulence model. The turbulence models gave results which generally compared no better with experimental data than the laminar computation results.

A finite-volume algorithm, incorporating a non diffusive quadratic scheme for the approximation of convection and full second-moment (Reynolds-stress-transport) turbulence closure, is applied to a free jet in moderately strong cross-flow and three jet configurations combining impingement with weak cross-flow, one geometry involving a twin-jet and another a triple-jet arrangement. The primary objective is to identify the merits and weaknesses of Reynolds-stress modelling, in contrast to one based on the isotropic eddy-viscosity approach, in the present complex 3D environment. While open questions remain, due principally to uncertainties arising from boundary conditions and insufficient numerical resolution in isolated highly sheared regions the present calculations provide clear indications, in accord with earlier studies in both 2D and 3D flows, of the superiority of the anisotropic closure. It is also demonstrated that a careful treatment of the jet-discharge conditions can be highly influential in respect of predictive realism. Author

The k-epsilon model and a second moment closure have been applied to the calculation of a slighted heated jet issuing into a cross-flow. Two jet to cross-flow velocity ratios were considered. An assessment of the model performance is made difficult by the high turbulence intensities observed in the recirculation region in the lee of the jet and consequent uncertainty in the hot-wire measurements. Overall, the second moment closure gives slightly better agreement but the difference between the results obtained with the two model is not large. For the low velocity ratio, results are extremely sensitive to the boundary conditions prevailing at jet inlet. The predicted mean temperature profiles appear to be more strongly dependent on the predicted velocity fields than on the scalar field closure. Author

(AGARD-CP-534) Copyright Avail: CASI HC A03/MF A04

Flowfields of two and three dimensional subsonic jets injected into a crossflow were solved by using a three dimensional Navier-Stokes code (LANS3D). Baldwin-Lomax turbulence model and the algebraic curved jet turbulence model of Oh and Schetz were used depending on the location in the flowfield. Application of characteristic boundary conditions based on Riemann invariants were found to be useful for the convergence of solutions. Computations made using flat bottom grids showed local pressure singularities around the jet exit. It was shown that these singularities could be removed by using grids with a cavity for the jet entrance. Grid skewness was a particularly effective parameter on the prediction of surface pressures. A review of recent activities focused on the simulation of transverse jet interaction problems using advanced time-asymptotic and time-accurate Navier-Stokes methodology is presented. Missile work has involved the simulation of short-duration control jets issued from solid rocket motor nozzles. For the simulation of time-accurate particle-laden flows, a new Eulerian-based upwind/implicit particle-solver was developed and coupled with the gas-phase solver. Rotorcraft work has involved simulating the interaction of the exhaust plumes with the rotor wake and body aerodynamic flow. Hybrid vortex tracking/Navier-stokes methodology has been implemented with gridding of this complex 3D interactive flow being an issue of primary concern. Propulsive work has emphasized turbulence modeling. For scramjet fuel-injection applications, compressible-dissipation extensions to the k-epsilon turbulence model which provided marked improvements in simulating fundamental high-speed shear layers, have proven to work quite well for transverse jet injection.

At present there is limited information available on effects of free-stream turbulence intensities and scale on both the time average and instantaneous development of a jet in a cross flow. The aim of this study was to investigate such effects on both entrainment and mean path of the jet using primarily experimental methods. The experimental part consisted of measurements using hot wire anemometers, thermocouples and a nine hole vortex probe as well as observations with a color Schlieren system on a jet issuing from a circular aperture in a flat plate. The jet Reynolds numbers of the tests were in the region 2x10(exp 4) to 8x10(exp 4) and the flow could be considered as incompressible for all cases tested. The use of both visualization technique as well as quantitative measurements have proven to be helpful in the description of free-stream turbulence effects. Although it should

be noted that some quantitative data can be inferred from the Schlieren observations. The results show that there are clear effects due to variations in free-stream turbulence on the development of the jet. The effects within the range of variation in free-stream turbulence intensity and length scale of the investigation are manifest in terms of all main jet characteristics. These characteristics are the rate of entrainment, the mean jet path and the strength of the main jet vortices. The observed effects are significant, but at present there are no direct trends in the results with increasing or decreasing turbulence scales or intensity to help propose the primary mechanisms involved in the effects. This is the subject of further investigations at the present time. Author

An experimental investigation was conducted to examine the operating and spray characteristics of two internal-mixing twin-fluid atomizers that were designed to produce effervescent atomization at low air/liquid mass ratios (ALR's). These two experimental atomizers ejected the two phase flow so as to produce a wide spray angle. One atomizer was a plain orifice design that used a four-hole exit orifice which divided and turned the two phase flow just prior to ejection. The other atomizer, called the conical sheet atomizer, ejected the two phase flow through an annular passage in such a way as to form a hollow cone spray. The atomizer operating parameters varied during this investigation were the air/liquid mass ratio, atomizer operating pressure, and, in the case of the conical sheet atomizer, the exit gap width. Studies of spray characteristics included measurements of the spray Sauter mean diameter (SMD), drop size distribution, and, for the conical sheet atomizer, circumferential distribution of the liquid mass within the spray. For both atomizers it was found that SMD decreases with an increase in either ALR or operating pressure. The effect of ALR on SMD diminishes as the value of ALR increases. For the conical sheet atomizer, when operating at low values of pressure and ALR, SMD increases with increase in gap width, but the influence of gap width on SMD diminishes with an increase in either pressure or ALR. At the highest operating pressure of the conical sheet atomizer (552 kPa), SMD is independent of gap width at all ALR's. For both atomizers, changes in operating pressure and ALR have little effect on the distribution of drop sizes in the spray. Author (revised)

The flow resulting from an airblast atomizer with prefilmer and corotating swirl was investigated in a cylindrical combustion chamber. Gas and droplet velocities were measured by a phase Doppler anemometer and species and gas temperature by gas sampling probes respectively, thermoelements at atmospheric conditions and without fuel and air preheat. Because of interference with the liquid phase, the species measurements were restricted to a minimum distance of 40 mm from the atomizer lip. The temperature measurements showed the dominating influence of the external recirculation zone on flame stabilization for the investigated nozzle configuration with a small expansion angle of the swirling flow. The species concentration fields exhibit homogeneous radial profiles at an axial distance of 100 mm behind the atomizer, although droplets are observed up to 140 mm. Integrating the measured liquid volume flux density profiles, it was found that the fuel flux at 45 mm behind the atomizer had diminished to 14 percent of the maximum measured value. The axial profile of the liquid flux weighted Sauter mean diameter is almost linearly increasing from 22 to 31 micrometers. Systematic experimental errors and losses of the system sensitivity, which enter the results partly with opposite signs, have an influence on the measured flux densities and moments of the particle size distribution. The measurement of individual flux density profiles was reproducible to within 45 percent. A comparison between the gas flow in the nearfield of the atomizer under reacting and nonreacting conditions showed a partial suppression of the expansion of the velocity profiles by the hot corner vortex. Together with the combustion induced axial acceleration, the thus effected reduction of the effective swirl number leads to the breakdown of the recirculation at 29 mm. Author (revised)

Locally and time-resolved measurements of the velocity, temperature, and species concentration in a three dimensional jet-stabilized combustor are presented. The combustor was developed at the Institute for Thermal Turbomachinery, University of Karlsruhe, for extended benchmark experiments. For the present investigation, the combustor was fired by propane. The profiles of the velocity, temperature, and species distribution were determined at seven planes along the combustor axis. A comparison between the cold flow and the reacting hot gas conditions is given. The time-resolved velocity and temperature measurements were performed by a two component LDA-system as well as specially designed and optimized thermocouple probes. The time-dependent analysis demonstrates that the velocity and turbulence and/or the temperature fluctuations are dramatically increased under hot combusting conditions. Finally, the locally determined species distributions are compared with the global concentrations at the exit of the combustor providing a data base for numerical tests.

Lecture notes for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Progress in Transition Modelling' have been assembled in this Report. The aim and scope of this Course was to provide information on new developments in modelling the dynamics of transition to turbulence, and the prediction of transition in boundary-layer flows. Specifically, topics and methods covered include: a physical description of boundary-layer transition, linear theory, asymptotic techniques, parabolized stability equations, direct numerical simulations, empirical methods and closure of the Reynolds' averaged Navier-Stokes equations. The material assembled in this report was prepared and presented under the combined sponsorship of the AGARD Fluid Dynamics Panel, and the von Karman Institute (VKI) for Fluid Dynamics. For individual titles, see N94-33885 through N94-33890.

The problems of understanding the origins of turbulent flow and transition to turbulent flow are the most important unsolved problems of fluid mechanics and aerodynamics. It is well known that the stability, transition, and turbulent characteristics of bounded shear layers are fundamentally different from those of free shear layers. Likewise, the stability, transition, and turbulent characteristics of open systems are fundamentally different from those of closed systems. Because of the influence of indigenous disturbances, surface geometry and roughness, sound, heat transfer, and ablation, it is not possible to develop general prediction schemes for transition location and the nature of turbulent structures in boundary-layer flows. At the present time no mathematical model exists that can predict the transition Reynolds number on a flat plate. The recent progress in this area is encouraging, in that a number of distinct transition mechanisms have been found experimentally. The theoretical work finds them to be amplitude and Reynolds-number dependent. The theory remains rather incomplete with regard to predicting transition. Amplitude and spectral characteristics of the disturbances inside the laminar viscous layer strongly influence which type of transition occurs. The major need in this area is to understand how freestream disturbances are entrained into the boundary layer, i.e., to answer the question of receptivity. We refer receptivity to the mechanism(s) that cause freestream disturbances to enter the boundary layer and create the initial amplitudes for unstable waves.

The objective of this paper is to discuss the possibilities of transition prediction by using the eigenvalues of the classical linear stability equations. Emphasis is placed on the e(sup n) method, with applications to two- and three-dimensional flows. It is shown that the value of the n factor at the onset of transition depends on the disturbance environment. On swept wings, it depends also on the procedure which is adopted to integrate the growth rates. In spite of its shortcomings (the receptivity and the nonlinear processes are not accounted for), the e(sup n) method is useful for parametric studies. Applications to the attachment line flow and to the Gortler instability are also presented. Author

The linear and nonlinear evolution of unstable disturbances in high-Reynolds-number flows is reviewed from the perspective of asymptotic theory. For non-parallel and/or unsteady flows, quasi-parallel and quasi-steady approximations can only be strictly justified by asymptotic expansions based on the smallness of the inverse Reynolds number. Further, such an asymptotic approach allows the inclusion of nonlinear effects in a self-consistent manner. Attention is focussed primarily on three asymptotic regions: the lower-branch Tollmien-Schlichting (TS) scaling for boundary layers, the upper-branch TS scaling for boundary layers, and the Rayleigh scaling for (decelerating) boundary layers, free shear layers, jets and wakes. For fixed frequency disturbances in a decelerating boundary layer, these asymptotic regions occur at increasing distances from the leading edge. A disturbance propagating downstream from the leading edge will pass through each region in turn. The larger the initial disturbance, the further upstream nonlinear effects must be taken into account. Weakly nonlinear theory is possible when the relative growth-rate of disturbances is small, e.g. near a neutral curve. Close to the lower branch, it is possible to take into account non-parallelism, wavetrain modulation (i.e. wavepackets), and three dimensional effects such as those that lead to TS-wave/vortex interactions. A number of different models are described and critically assessed. Similar possibilities are examined on the upper-branch scaling, where an additional feature is the effect of nonlinear critical layers. Critical layers play a preeminent role on the Rayleigh scaling. Physical effects explained include the nonlinear saturation of two-dimensional disturbances in free shear layers and decelerating boundary layers, the explosive growth in amplitude of three dimensional disturbances, and the generation of surprisingly large longitudinal vortices and spanwise-dependent mean flows. The parabolized stability equations (PSE) are a new approach to analyze the streamwise evolution of single or interacting Fourier modes in weakly nonparallel flows such as boundary layers. The concept rests on the decomposition of every mode into a slowly varying amplitude function and a wave function with slowly varying wave number. The neglect of the small second derivatives of the slowly varying functions with respect to the streamwise variable leads to an initial boundary-value problem that can be solved by numerical marching procedures. The PSE approach is valid in convectively unstable flows. The equations for a single mode are closely related to those of the traditional eigenvalue problems for linear stability analysis. However, the PSE approach does not exploit the homogeneity of the problem and, therefore, can be utilized to analyze forced modes and the nonlinear growth and interaction of an initial disturbance field. In contrast to the traditional patching of local solutions, the PSE provide the spatial evolution of modes with proper account for their history. The PSE approach allows studies of secondary instabilities without the constraints of the Floquet analysis and reproduces the established experimental, theoretical, and computational benchmark results on transition up to the breakdown stage. The method matches or exceeds the demonstrated capabilities of current spatial Navier-Stokes solvers at a small fraction of their computational cost. Recent applications include studies on localized or distributed receptivity and prediction of transition in model environments for realistic engineering problems. This report describes the basis, intricacies, and some applications of the PSE methodology. Author

The calculation of engineering flows undergoing laminar-turbulent transition presents special problems. Mean-flow quantities obey neither the fully laminar nor the fully turbulent correlations. In addition, local maxima in skin friction, wall temperature, and heat transfer often occur near the end of the transition region. Traditionally, modeling this region has been important for the design of turbine blades, where the transition region is long in relation to the chord length of the blade. More recently, the need for better transition-region models has been recognized by designers of hypersonic vehicles where the high Mach number, the low Reynolds number, and the low-disturbance flight environment emphasize the importance of the transition region. Needless to say, a model that might work well for the transitional flows typically found in gas turbines will not necessarily work well for the external surface of a hypersonic vehicle. In Section 2 of this report, some of the important flow features that control the transition region will be discussed. In Section 3, different approaches to the modeling problem will be summarized and cataloged. Fully turbulent flow models will be discussed in detail in Section 4; models specifically designed for transitional flow, in Section 5; and the evaluation of models, in Section 6.

Detailed experimental and theoretical flow field studies were carried out for a high pressure ratio impeller with a high flow coefficient associated with transonic inlet flow. Experimental data were obtained by using the Laser-Two-Focus velocimetry. A 3D viscous code was applied to calculate the flow field. Comparisons between measured and calculated data are presented for 10 cross flow planes with special attention given to the impeller inlet, which is where the transonic flow occurs. Author (revised)

The method described in this paper allows the detailed design of a complete radial impeller geometry starting from a prescribed suction and pressure side velocity distribution at the hub and shroud. The average velocity at the hub and shroud is used to define the meridional contours. The corresponding blade loading is used to define the blade shape at the hub and shroud. Impellers designed with this method were analyzed by a quasi 3D finite element analysis method. Results show good agreement between the imposed and the calculated Mach number distribution. The method was complemented with an inverse Euler solver capable of designing shock free transonic blades on the previously defined axisymmetric streamsurface. Compared to other inverse methods, this one has the advantage of starting from the velocity distribution itself and requires only a small amount of computer time.

Topic of this contribution is a single stage mixed flow compressor with 6:1 pressure ratio, which is under development as a component for a turbojet. Primary design aim for the stage was to achieve minimum frontal area at a high efficiency level. Excerpts of the considerations and calculations for determining the design rotational speed and the main dimensions of this mixed flow compressor stage are presented first. Some explanations concerning the definition of the meridional contours and the generation of the blading are given, supplemented by several results of the impeller flow calculations. After a brief description of the test rig and its instrumentation, the measured impeller characteristics are presented. They show that the impeller meets its design pressure ratio and exceeds the efficiency target. For selected operating points the measured pressure distributions along the impeller outer contour are compared with the predicted static pressure rise. The discussions of the test results closes with the measured mixed flow compressor map which reveals that the overall stage performance does not fully meet the design goals, mainly because of high losses in the diffusing system.

Starting from two existing cascades a new one was developed for the same inlet and exit flow conditions but increased pitch to chord ratio: inlet Mach number M(sub 1) = 1.09, flow turning Theta = 14 degrees, and pitch to chord ratio s/c = 0.8. Perspective research goal is the determination of the loading limits of transonic compressor cascades. The design was performed in the direct mode using a two dimensional Euler code coupled iteratively with an integral boundary layer code generating a profile Mach number distribution that avoids boundary layer separation. The experiments in a transonic cascade wind tunnel revealed performance, profile, Mach number distribution, and wake traverse data. A laser, two focus measurement technique was used to analyze the flow field upstream of the cascade and around the leading edge. The experimental results are analyzed by the Euler code. To improve the reliability of experimental as well as numerical inlet flow angle determination, the influence of conventional inlet boundary conditions versus so called nonreflecting boundary conditions was tested and verified using the L2F results.

A control volume finite difference method based on the work of Rhie in conjunction with a two layer turbulence model has been used to predict mean velocities, turbulent kinetic energy, and film effectiveness profiles downstream of a single round jet normal to cross stream at a mass flux ratio of unity. Computations were obtained for domain discretizations in which (1) the jet velocity,

and turbulent kinetic energy profiles were specified at the inlet to the cross flow, and (2) the jet delivery tube and the cross flow were solved for simultaneously using a multiblock approach. The multiblock solutions were carried out for both a circular and rectangular representation of the jet. The numerical results are compared to experimental measurements available in the open literature. The comparisons indicate that the modeling of the hole as circular or rectangular had only a small influence on the predicted flow field and film effectiveness downstream of the hole. However, when jet inlet profiles are specified (rather than calculated), the resulting flow field predictions show deviations from the multiblock solutions especially in the near hole region. This leads to poor agreement between predicted and observed film effectiveness distributions. Author

The tools used at Dassault Aviation to calculate the limits on laminar layers, transition criteria and analyses on linear stability are presented and analyzed as far as their precision but also as far as their effectiveness when they have to be used to optimize the design of aircrafts' wing systems. These calculations were used in the concept of laminar deviation that was tested in the air on a FALCON 50, and in the concept of a wing with an hybrid laminarity that was tested in the air on a FALCON 50 during a second phase, 1987-1990. Computational Fluid Dynamics (CFD) has become a major design tool for designers of turbomachinery. The progress in this area is fast, and the use of 3-D methods is becoming increasingly applicable to the design process. This Lecture Series will include: (1) Computational methods for preliminary design and geometry definitions; (2) Methods for computing through-flows, blade-to-blade flows and geometry generation; (3) Optimization strategies; (4) Designing in three dimensions; (5) Code validation, mesh influence on solution accuracy; (6) Turbulence and transition modelling; (7) Comparison of time averaged flow solvers and 3-D unsteady CFD codes; (8) Industrial use of CFD and the points of view of the designers. For individual titles, see N95-14128 through N95-14136.

The essential problem today, in the application of 3D Navier-Stokes simulations to the design and analysis of turbomachinery components, is the validation of the numerical approximation and of the physical models, in particular the turbulence modelling. Although most of the complex 3D flow phenomena occurring in turbomachinery bladings can be captured with relatively coarse meshes, many detailed flow features are dependent on mesh size, on the turbulence and transition models. A brief review of the present state of the art of CFD methodology is given with emphasis on quality and accuracy of numerical approximations related to viscous flow computations. Considerations related to the mesh influence on solution accuracy are stressed. The basic problems of turbulence and transition modelling are discussed next, with a short summary of the main turbulence models and their applications to representative turbomachinery flows. Validations of present turbulence models indicate that none of the available turbulence models is able to predict all the detailed flow behavior in complex flow interactions. In order to identify the phenomena that can be captured on coarser meshes a detailed understanding of the complex 3D flow in compressor and turbines is necessary. Examples of global validations for different flow configurations, representative of compressor and turbine aerodynamics are presented, including secondary and tip clearance flows. Author

The impact of recent research activities in unsteady flows and flow simulation methods used in the turbine design process are outlined. Results from a number of experimental investigations are described to quantify the effect of unsteadiness on the time-averaged flows in turbines. Results from numerical simulations, obtained by using 3-D unsteady Computational Fluid Dynamics (CFD) codes, are also shown to indicate that some of the unsteady flow features can be fairly accurately predicted. An overall discussion is presented to distinguish flow parameters that can be modeled with existing steady CFD codes, from those that require unsteady codes. Author

The numerical simulation of the internal flowfield now plays a major role in all turbomachinery aerodynamic designs, from aero-engines to hydraulic turbines and pumps. With the help of CFD codes an experienced designer is able to produce more adventurous, better engineered and more clearly understood designs more rapidly at lower cost. This paper reviews the use of CFD as an engineering tool in modern turbomachinery design from the standpoint of a turbomachinery designer. Particular attention is given to the current limitations with regard to performance prediction. The necessary engineering criteria used by turbomachinery designers to overcome these limitations and to assess the weak points of their designs using CFD flowfield computations are discussed. Examples of the application of these general aerodynamic design criteria to most classes of turbomachines using a variety of different CFD codes are given. Author

CFD tools represent a significant source of improvements in the design process of turbomachinery components, leading to higher performances, cost and cycle savings as well as lower associated risks. Such methods are the backbone of compressor and turbine design methodologies at Snecma. In the 80's, the use of 3D Euler solvers was a key factor in designing fan blades with very high performance level. Counter rotating high speed propellers designed with this methodology reached measured performances very close to their ambitious objective from the first test series. In the late 80's and the beginning of the 90's, new, more powerful methods were rapidly developed and are now

commonly used in the design process: a quasi-3D, compressible, transonic inverse method; quasi-3D and 3D Navier-Stokes solvers; 3D unsteady Euler solvers. As an example, several hundred 3D Navier-Stokes computations are run yearly for the design of low and high pressure compressor and turbine blades. In addition to their modelling capabilities, the efficient use of such methods in the design process comes from their close integration in the global methodology and from an adequate exploitation environment. Their validation, their calibration, and the correlations between different levels of modelling are of critical importance to an actual improvement in design know-how. The integration of different methods in the design process is described. Several examples of application illustrate their practical utilization. Comparisons between computational results and test results show their capabilities as well as their present limitations. The prospects linked to new developments currently under way are discussed. Over the last decade the role played by CFD codes in turbomachinery design has changed remarkably. While convergence/stability or even the existence of unique solutions was discussed fervently ten years ago, CFD codes now form a valuable part of an overall integrated design system and have caused us to re-think much of what we do. The geometric and physical complexities addressed have also evolved, as have the number of software houses competing with in-house developers to provide solutions to daily design problems. This paper reviews how GE Aircraft Engines (GEAE) uses CFD in the turbomachinery design process and examines many of the issues faced in successful code implementation. Author

The importance of CFD in the design of turbocomponents is no longer a matter of discussion. Since the fundamental publications of Wu and the first successful attempts to determine the potential 2D flow in blade rows the position of computational fluid dynamics in the design of jet-engine turbocomponents has increased continuously. This mainly has been driven by the two factors 'time' and 'cost'. As a result the design engineer of today can rely on a mature set of numerical approaches for the aerodynamic optimization of turbomachines. This design system is structured differently in the specific companies. Generally, however, an inverse correlation between the complexity of the problem and the complexity of the numerical approach can be observed: The most complex problems rely on relatively simple codes with a big portion of empiricism and vice versa. An overview of the design problems and the application of computational methods is given. Author

This report presents the results of a study by Working Group 14 of the AGARD Fluid Dynamics Panel. This group was formed to establish an accessible, detailed experimental data base for the validation of Computational Fluid Dynamics (CFD) codes. The thirty nine test cases that are documented cover the subsonic, transonic, and supersonic flow regimes and five classes of geometries. Included in the five classes of geometries are: two dimensional airfoils; three dimensional wings, designed for predominantly attached flow conditions; slender bodies, typical of missile type configurations; delta wings, characterized by a conical type of vortex flow; and complex configurations, either in a geometrical sense or because of complicated flow interactions. The report is presented in two volumes. Volume 1 provides a review of the theoretical and experimental requirements, a general introduction and summary of the test cases, and recommendations for the future. Volume 2 contains detailed information on the test cases. The relevant data of all test cases has been compiled on floppy disks, which can be obtained through National Centers. Author

The data presented in this contribution were obtained in the DLR Transonic Wind Tunnel Braunschweig. The intent of the experiment was to provide data giving information on the development of the TWB-side wall boundary layer in the presence of a typical transonic airfoil model for further investigation of the influence of the side wall boundary layer on 2-D airfoil measurements. For this purpose boundary layer pitot pressure were measured in 13 different side wall positions around the airfoil. Airfoil pressure distributions were obtained in several spanwise positions by sliding the airfoil model in a spanwise direction. The test cases investigated correspond to the design conditions of the airfoil (Ma = 0.73, alpha = 1.5 deg) and to a slow (alpha = 0 deg) and a high (alpha = 3.0 deg) lift value at the same Mach number. For these cases wall pressure distributions were measured on the center slat of the top and bottom walls. Additionally to the pressure measurements some oil flow pictures were made on the upper airfoil surface and the adjacent wind tunnel side wall to get more insight in the structure of the flow. In order to have well defined wind tunnel boundary conditions for the evaluation by computational methods, the slotted top and bottom walls of the test section were closed for these specific tests. This means, of course, that the presented airfoil pressure distributions do not correspond to free flight conditions and are not comparable to wind tunnel results obtained in slotted or perforated transonic test sections. The data presented in this contribution were obtained in the F2 subsonic wind tunnel of the ONERA Fauga-Mauzac Center. The objective of this work was to obtain detailed experimental

data on a separated vortex flow. The model shape has been chosen to be as simple as possible in order to facilitate the mathematical modeling. This model has been defined after preliminary studies in a water tunnel. The present document reports the results obtained with an axisymmetric model at incidence. Attention has been focused on the boundary layer evolution in the zone of separation and on the mechanism leading to the formation of a well detached primary vortex. The flow has been investigated in great detail by using several experimental techniques: surface flow visualizations, surface pressure measurements, field explorations by multihole pressure probes, and an LDV system. Measurements on a non-circular body were made in ONERA wind tunnels. This body, representative of non-conventional missile shapes, was studied for Mach numbers from 0.4 to 3.0 (S2MA wind-tunnel) and 4.5 (S3MA wind-tunnel), angles of attach up to 20 deg and sideslip angles up to 10 deg, with a free transition. The data base consists of static pressure measurements. The intent of the experiment was to provide data for evaluation of three-dimensional flow computation methods, as part of a research program sponsored by the 'Direction des Recherches, Etudes et Techniques' of the French Ministry of Defense. The flow exhibits large separation regions and strong vortices, even at low angles of attack, due to the particular shape of the body (lenticular cross-section). Author

Numerical monotone methods for integration of the Reynolds averaged Navier-Stokes equations are presented. These methods employ finite volume formulation, implicit high-order accuracy Godunov type scheme and two-equation (q - omega) turbulence model, based on integration up to the wall. To illustrate the typical peculiarities of these methods the computations of viscous flows in curvilinear ducts, around 2D airfoils and 3D shock-wave boundary layer interaction are considered. Available experimental data are used for verification of the computed results. Author

A brief review is presented of work by the authors to provide an engineering prediction technique for power intensity (rms fluctuating pressure) and power spectral density (PSD) for attached and separated compressible flow. The review process also considers recent shock/turbulent boundary layer interaction work conducted at the University of Texas at Mach 5. It is shown that prediction techniques are hampered as the result of the requirement to know parameters of flow interactions a priori; in particular, the choice of characteristic length and velocity scales. A technique is presented, based on the Houbolt spectra assumption, that appears to provide engineering solutions to the design resolution of complex flow problems. The method is based on a first moment type of PSD (f.phi(f)/(Rho sub OA)squared) that has a fixed value for attached and separated flows. Moreover, when applying the concept with the Houbolt spectra, an excellent comparison is shown to PSD data for shock/turbulent boundary layer interactions. Author (revised)

The 31 papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium on 'Wall Interference, Support Interference, and Flow Field Measurements' are contained in this report. In addition, a Technical Evaluator's Report assessing the success of the Symposium in meeting its objectives, and an edited transcript of the General Discussion held at the end of the meeting are also included. The primary objective of this Symposium was to report on recent developments from research and technology programs aimed at reducing test data errors caused by wind tunnel walls, model supports, and intrusive flow field measurement devices. The scope of papers included wall interference correction methods based on measured data at the walls and methods to eliminate wall interference through adaptive and/or ventilated walls, support interference calculations and correction methods, and recent advances in flow field measurement techniques. For individual titles, see N95-19252 through N95-19282.

The requirements, current technology status, and future needs for methodologies to assess wall and support interference effects, and for flow field measurement capabilities, are addressed from an aircraft industry perspective. The requirement for higher Reynolds number testing, especially for transport aircraft, places a much greater burden on the development of the respective technologies. Accurate wall interference estimation methods, including modeling of the tunnel wall flow, are required to assure that models are sized such that wall effects are correctable.

Limitations of wall-interference correction methodologies, which occur as a consequence of current CFD inadequacies, are addressed. Flow field correction methods, as well as surface pressure correction methods, are covered. Three techniques for estimating model support interference are reviewed, namely, the use of dummy stings in experimental tests, use of empirically-based methods for similar installations, and use of CFD-based methods. The need to design support system concepts that minimize interference, and, in the process, permit the effective application of CFD-based methods, is highlighted. Flow diagnostic techniques needed to permit extrapolation of sub-scale wind-tunnel-measured aerodynamic characteristics to full-scale conditions, and to provide the understanding to allow deficiencies to be addressed and corrected, or to guide the design of improved-performance concepts, are reviewed. Both surface flow measurement/visualization and off-body measurements are considered. Noteworthy results obtained with current intrusive devices are reviewed, but the emphasis for the future is clearly shown to reside with optical, non-intrusive techniques such as pressure sensitive paint, infrared imaging, particle image velocimetry, and Doppler global velocimetry. The internal cooling of gas turbine blades is generally ensured by secondary air flowing through narrow passages existing inside the airfoils. These internal channels are usually connected by 180 deg turns with sharp bends. The aerodynamic and associated convective heat transfer characteristics observed in this type of geometry are significantly influenced by strong secondary flows and flow separations. The purpose of the present experimental effort is to give a detailed description of some aerodynamic aspects of this particular flow pattern. Detailed measurements of the three-dimensional velocity field were performed by means of a two-component Laser Doppler Velocimeter. The third velocity component was obtained by repeating the measurements at two different orientations of the emitting optics with respect to the test section. Author

BOUNDARY-FLOW MEASUREMENT METHODS FOR WALL INTERFERENCE ASSESSMENT AND CORRECTION: CLASSIFICATION AND REVIEW
P. R. ASHILL *In* AGARD, Wall Interference, Support Interference and Flow Field Measurements 21 p (SEE N95-19251 05-34) Jul. 1994 Sponsored by Dept. of Trade and Industry
(AGARD-CP-535) Copyright Avail: CASI HC A03/MF A04

The development of methods of determining wind-tunnel wall interference from measurements of the flow at a boundary adjacent to the wind-tunnel walls has required the collaboration of theoreticians and experimenters. After these methods are classified and reviewed, techniques for making the measurements are discussed and the concept of correcting wind-tunnel flows to equivalent free-air conditions is examined. Three classes of method are identified, two needing a model representation ('one-variable' and 'wall-signature' types) and a third needing no simulation of the flow around the model ('two-variable' methods). All three classes are related and the need for accuracy in the model representation in 'one-variable' methods can be relaxed by a suitable choice of 'mixed' boundary conditions. Further work is needed to establish non-intrusive techniques and to develop improved methods for determining the normal component of velocity at or just away from the measurement surface. The need for research to establish allowable limits on variations in wall-induced velocity in the region of the model is highlighted. Author

In the wind tunnel division of DLR in Braunschweig a wall correction method based on measured boundary conditions was developed. The verification of the method was made with theoretically calculated boundary conditions and with experimental test data. The calculation of the wall interferences from theoretical boundary conditions are in good agreement with exact reference data of the wall interferences. The advantage of the wall pressure correction method is shown by the results of the experimental tests where the measured coefficients of the force and the moments are compared with the corrected coefficients and the coefficients of free-flight. In this comparison the classical correction method is shown too. The wall correction method is easy to use because no information of the model is required and can be applied into an on-line processing. Particular attention should be paid to the wall pressure measurement system because wrong wall pressure data can have an influence on the calculated wall interferences. Author

Two large models with swept wings have been investigated in two rather similar tunnels, whose cross sectional areas differ by a factor of 9. The tunnels are configured with slotted walls. The larger of the tunnels has a ventilation of 8.3 percent, while the ventilation of the smaller tunnel has been varied between 4.2 percent and 8.3 percent for this investigation. The blockage of the tested models in the tunnels varied from approximately 0.2 percent to 1.7 percent. For the case with blockage of 1.7 percent the ratio of span to the width (equals to the height) of the tunnel was 0.8. For the configuration blocking 0.6 percent in the larger of the two wind tunnels the comparison of Mach number signatures on the tunnel walls between experiments and computations is very good at both Mach numbers, 0.9 and 0.95, and both angles of attack, 0 and 10 degrees. The position of the 'shock' is very well predicted in the computations. Most of the computational simulations for the model blocking 1.7 percent in the smaller of the two tunnels have so far been performed at Mach number 0.8 and at angles of attack of 0 and 2 degrees. This presentation has been concentrated on Mach number 0.8 and angle of attack of 2 degrees. However, a limited number of comparisons is given for other cases, like Mach number 0.8 with angle of attack 5 degrees and Mach number 0.95 with angle of attack 2 degrees. As can be seen the agreement is excellent for all Mach numbers and related angles of attack that have been investigated. Author

ESTIMATING WIND TUNNEL INTERFERENCE DUE TO VECTORED JET FLOWS
R. K. NANGIA *In* AGARD, Wall Interference, Support Interference and Flow Field Measurements 14 p (SEE N95-19251 05-34) Jul. 1994 Sponsored by Defence Research Agency

An important consideration in the testing of aircraft models with vectored jets is the allowance to be made for wind tunnel interference on jet flows. Depending on the cross-section dimensions, the wind tunnel interference, can be particularly severe at high incidences or for high jet velocities and large jet deflections. For assessment of these effects, either 'Wall pressure signature' or 'Direct' methods can be used. The wall pressure methods, although requiring dedicated instrumentation, have the advantage that model flow simulation is not required. The direct methods allow calculations of interference prior to the tests and can therefore assist in optimization of model geometry for a particular wind tunnel. A 'Direct' method for estimating wind tunnel interference due to

jet flows is described. A semi-empirical model of the jet plume, imaged in walls has been used to represent the tunnel constraint. Comparisons with results from a 'wall pressure signature' method are very encouraging. The results emphasize the large magnitudes of effects which can arise, particularly in experiments with 2, 3 or 4 vectoring nozzles on multi-surface aircraft configurations. For 4 nozzles with jet velocity ratio near 10, the vertical velocity flow angle can be near 6 - 8 degrees. The present technique offers the capability of guiding the design of acceptable experiments, or for checking the validity of existing information. Several aspects of future work have been proposed. A computational and experimental study has been undertaken to investigate methods of modelling solid and porous wall boundary conditions in computational fluid dynamics (CFD) codes. The procedure utilizes experimental measurements at the walls to develop a flow field solution based on the method of singularities. This flow field solution is then imposed as a pressure boundary condition in a CFD simulation of the internal flow field. The effectiveness of this method in describing the boundary conditions at the wind tunnel walls using only sparse experimental measurements has been investigated. Verification of the approach using computational studies has been carried out using an incompressible flow solver. The current work demonstrates this technique for low speed flows and compares the result with experimental data obtained from a heavily instrumented variable porosity test section. Position and refinement of experimental measurements required to describe porous wall boundary conditions have also been considered for application to other porous wall wind tunnels. The approach developed is simple, computationally inexpensive, and does not require extensive or intrusive measurements. It may be applied to both solid and porous wall wind tunnel tests. Some consideration is given to the extension of this method to three dimensions. Author

A wall interference prediction tool based on a boundary condition method is developed. The correction method, based on Green's theorem, gives the interference velocity potential field in the control volume from the velocities on a control surface around the model of interest without the need to model the flow field. The boundary velocities around separated wake flows are measured with static pressure pipes. This is done with both solid and partially open test section walls. The results are used for validation of the tool and to evaluate the possibilities to use static pressure pipes in low speed flows as a means to get the perturbation velocities needed to calculate blockage effects in nonsolid walls cases. This paper also describes some problems in estimating flow properties that are not measured. The results presented show that if the static pressure measurements are made carefully it is possible to resolve small cross flow velocities with the necessary accuracy for the correction method. The report presents a brief review of the investigation methods and results obtained for the key problems of the test procedure in the industrial sub- and transonic TSAGI wind tunnels. Among these are the flow calibration in 'empty wind tunnels', the wall interference minimization, and the interference with supporting devices. These problems can be solved only in the combination of the calculation and theoretical investigations with the tests carried out first in pilot facilities and then in large wind tunnels. As examples are given the results of the flow calibration both in the conventional conditions of a uniform test section flow and in a flow with the side wall boundary layer suction which is typical for two-dimensional model tests. The flow boundary influence is investigated by the calculation and experimental method of corrections which works well at angles of attack up to 50 degrees at M = 0.9. Good results are also obtained owing to the application of the adaptive perforation to reduce the wall interference on a large-scale civil plane model (blockage is 3.16 percent). The introduction of corrections for the sting-induced flow distortion over the model afterbody is discussed shortly. Author

Sidewall effects affect the pressure field around a 2D airfoil tested in wind tunnel, even on its central section. First, laser measurement results show the 3D boundary condition near sidewalls. Then, another experimental investigation points out on the model the perturbation due to sidewall effects. In the second part a numerical method is described (coupling between inviscid flow and sidewall boundary layer computations) which allows taking into account sidewall effects. Comparisons with experiments are shown. Finally, the numerical method is used to estimate the Mach number correction due to sidewall effects. Author

Simplifying assumptions are inherent in the analytic method previously used for the determination of wall interferences on a model in a wind tunnel. To eliminate these assumptions, a new code based on the vortex lattice method was developed. It is suitable for processing any shape of test sections with limited areas of porous wall, the characteristic of which can be nonlinear. Calculation of wall effects in S3MA wind tunnel, whose test section is rectangular 0.78 m x 0.56 m, and fitted with two or four perforated walls, have been performed. Wall porosity factors have been adjusted to obtain the best fit between measured and computed pressure distributions on the test section walls. The code was checked by measuring nearly equal drag coefficients for a model

tested in S3MA wind tunnel (after wall corrections) and in S2MA wind tunnel whose test section is seven times larger (negligible wall corrections). Author

Thermal management of future avionics modules will be a critical design issue. New advances in integrated circuit technology and electronic packaging will allow the design of densely populated electronics modules with potential power dissipation levels in excess of 1.0 W/cm(exp 2). While the module power level trend will be to increase, the maximum allowable junction temperature for integrated circuits may be lowered to provide more benign thermal environment for electronics. This negates the use of conventional thermal management techniques in new avionics applications. A number of trade studies were performed to determine which cooling technique would be best suited to meet the anticipated reliability and performance requirements for the year 2005 and beyond. The approaches to module cooling technologies considered were: edge cooled conduction, immersion, and hollow core flow-through. The technology selected was the hollow core flow-through. This paper discusses the results of flow-through cooling investigations on both single-pass cold plates and SEM-E modules. Author

Due to increasing heat dissipation requirements, the need for an advanced cooling technique in current military avionics has been recognized. Immersion cooling with phase change has been demonstrated in a Format E clamshell module as an alternative. This module is capable of dissipating more than 700 Watts. From the development of the Format E clamshell module the AAS&T (Advanced Avionics Subsystems and Technology) Program has begun an effort to utilize the clamshell module in the development of a 3/4 ATR Format E Standard Avionics Enclosure utilizing immersion/change of phase cooling. The power dissipation requirement for the enclosure is 6500 Watts minimum. The cooling medium for both efforts is a Fluorinert (FS-72). The FS-72 is an environmentally safe coolant. As the need for greater heat removal and reliability increases, cooling technology must become more advanced to meet the needs of next generation aircraft. Author

The purpose of this presentation is the proposal of a novel, highly sophisticated cooling technique with a promising performance, but with a very early status of development - the microchannel heat pipe cooling. This technique can be directly adapted to the basic idea of Modular Avionics resulting on the hardware side in a modular packaging design with interchangeable modules. Due to the early status of the development and of the basic research some of the very stringent requirements for military airborne equipment are not met yet (or information is missing) like the impact of acceleration and orientation; nevertheless, the normal performance capability is highly compliant with the dramatically increasing local maximum heat densities and total maximum heat dissipations, which are forecast for future avionic applications. The presentation shall highlight the status of the development and the benefits of this technique; the latter is done by a comparison to the well established cooling methods for the module like Liquid Flow Through (LFT) and conduction cooling, in order to provide a clear impression of the cooling capabilities. Especially if the microchannel heat pipe is combined with a micro heat exchanger for the heat transfer off the module, the performance with respect to the maximum local heat density, the most challenging requirement for the future, is high in excess of the LFT method. The papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium on 'Application of Direct and Large Eddy Simulation to Transition and Turbulence', which was held April 1994 in Greece are contained in this report. In addition, a Technical Evaluator's Report assessing the success of the Symposium objectives, and an edited transcript of the General Discussion are also included. In the past two decades significant progress has been made in the numerical simulation of turbulent flows. Vast improvements in speed and memory size of modern supercomputers, and recent progress in simulation algorithms and parallel computation have put us on the threshold of being able to simulate flows in configurations of engineering interest. For individual titles, see N95-21062 through N95-21098.

The dynamic modeling procedure for large eddy simulation of turbulent flows is reviewed and recent developments in the theoretical aspects and applications are described. Methods for inclusion of backscatter of energy from small to large scale motions are presented. New formulations of the dynamic procedure are proposed which are optimized based on the subgrid scale flux vector or the energy dissipation rate instead of the subgrid scale stress tensor. Recent results from application of the model to forced isotropic turbulence with an inertial subrange, flow over a backward facing step at Reynolds number of 28000, and flow over a concave curved surface are presented. The dynamic subgrid scale model had been used in the Large Eddy Simulation (LES) of turbulent flow in a straight square duct. The Reynolds numbers considered, (based on the friction velocity and the duct halfwidth), are varying from 150 to 1125. The results obtained are in good agreement with the reference Direct Numerical Simulation (DNS) and experimental data. The accuracy and suitability of the model in high Reynolds number finite difference computations of three dimensional non-equilibrium flows is investigated. The influence of approximate wall boundary conditions in such flow cases is also addressed. Author

Most applications of the dynamic subgrid-scale stress model use volume- or planar-averaging to avoid ill-conditioning of the model coefficient, which may result in numerical instabilities. A spatially-varying coefficient is also mathematically inconsistent with the model derivation. A localization procedure is proposed here that removes the mathematical inconsistency to any desired order of accuracy in time. This model is applied to the simulation of rotating channel flow, and results in improved prediction of the turbulence statistics. Author

The long-time, asymptotic state of rotating homogeneous turbulence at high Reynolds numbers has been examined using large-eddy simulation of the incompressible Navier-Stokes equations. The simulations were carried out using 128 x 128 x 512 collocation points in a computational domain that is four times longer along the rotation axis than in the other directions. Subgrid-scale motions in the simulations were parameterized using a spectral eddy viscosity modified for system rotation. Simulation results show that in the asymptotic state the turbulence kinetic energy undergoes a power-law decay with an exponent which is independent of rotation rate, depending only on the low-wavenumber form of the initial energy spectrum. Integral lengthscale growth in the simulations is also characterized by power-law growth; the correlation length of transverse velocities exhibiting much more rapid growth than observed in non-rotating turbulence. We present a priori and a posteriori test results of LES (large eddy simulation) of compressible flow over a flat plate and in a mixing layer. Through a comparison with filtered DNS (direct numerical simulation) data the 'quality' of subgrid-models for the turbulent stress can be assessed. In particular, the scale similarity model of Bardina and the dynamic mixed model arising from a combination of Bardina's model with the Germano eddy-viscosity model show excellent correlations a priori, and give rise to accurate LES simulations a posteriori. Moreover, the filtering approach close to solid walls is considered and the contribution to the filtered equations arising from the non-commutation of the filter operator with the partial derivatives is calculated. It appears, in a priori tests for 2D simulations, that these non-commutation terms can be comparable to the turbulent stress. The scale similarity hypothesis yields models for these terms which show a good correlation. Author

Direct numerical simulations (DNS) of fully developed turbulent pipe flow and sudden pipe expansion flow with an expansion ratio of ER = 1.2 have been performed. The former DNS provides inflow conditions for the latter. The upstream Reynolds number, based on friction velocity and pipe diameter is 360 or 6950 based on mean centerline velocity. This is too low a Reynolds number to obtain a universal logarithmic law of the wall. Moreover, transverse curvature effects are observed when the data are compared with DNS data of Kim, Moin, Moser in the plane channel. The reason for these effects is that the streak spacing is of the same order of magnitude as the pipe radius. Hence, the pipe expansion flow will also reflect transverse curvature effects. The mean reattachment length is 10.1 step heights. Instantaneous and statistical flow variables are presented. They give an impression of the complex flow dynamics in the free shear layer, the recirculation and reattachment regions. Author

Smagorinsky and structure-function models are applied to the large eddy simulation of the turbulent flow over a cavity at a Reynolds number Re = 63,600. The near-wall flow region is modeled by implementing either a logarithmic law-of-the-wall or an exponential damping function. Results obtained with two values of the Smagorinsky constant, C(sub s) = 0.10 and 0.20, have been compared. Further, the results provided by the mentioned subgrid-scale models are compared with those obtained using the standard kappa-epsilon model. As a basis for the comparison, LDV measurements of mean and fluctuating turbulent quantities are also reported. The computational results have demonstrated that the use of large eddy simulation is clearly rewarding in face of kappa-epsilon model computation, yielding better results employing a similar number of grid nodes. Large-eddy simulation of turbulent channel flows over a one-sided periodically ribbed wall has been performed. Large-scale nonsteady structures have been correlated with the statistical values of the turbulent flow field. It is shown, that high turbulent kinetic energy and vortex shedding appear at the same location. The shedding of vortical structures from the edge of the rib is the dominating turbulent phenomena of the flow. The instantaneous behavior of the large-scale vortical structures is visualized and their interaction with the highly fluctuating recirculation zones is observed. Author

Direct and large eddy simulations of forced and decaying isotropic turbulence have been performed using a pseudospectral and a finite-difference code. Subgrid models that include a one-equation subgrid kinetic energy model with and without a stochastic backscatter forcing term and a new scale similarity model have been analyzed in both Fourier space and physical space. The Fourier space analysis showed that the energy transfer across the cutoff wavenumber k(sub c) is dominated by local interaction. The correlation between the exact and the modeled (by a spectral eddy viscosity) nonlinear terms and the subgrid energy transfer in physical space was found to be quite low. In physical space, a similar correlation analysis was carried out using top hat filtering. Results show that the subgrid stress and the energy flux predicted by the subgrid models correlates very well with the exact data. The scale similarity model showed very high correlation for reasonable grid resolution. However, with decrease in grid resolution, the scale similarity model became more uncorrelated, when compared to the kinetic energy subgrid model. The subgrid models were then used for large-eddy simulations for a range of Reynolds number. It was determined that the dissipation was modeled poorly and that the correlation with the exact results was quite low for all the models. In general, for coarse grid resolution, the scale similarity model consistently showed very low correlation while the kinetic energy model showed a relatively higher correlation. These results suggest that to use the scale similarity model relatively fine grid resolution may be required, whereas, the kinetic energy model could be used even in coarse grid. Author

The Narrow Channel (NC) assumption, together with a simple although efficient numerical scheme are adopted in order to perform the Direct Numerical Simulation (DNS) of turbulent channel flows at moderate Reynolds numbers with extremely reduced computational resources. Typical results are presented for a constant property fluid, which certify the reliability of the numerical tool and the quality of the simulations. The closure problem of turbulence modeling is then considered and the transport equations for the Reynolds stresses and for the dissipation rate of the turbulence kinetic energy are solved on the basis of the Narrow Channel data. The comparison of the distributions of the various terms in the transport equations with published full channel DNS data confirms that, although the NC assumption substantially reduces the computational cost of the simulations, it does not affect the accuracy of the numerical predictions. Finally, as an example of the use that can be done of the numerical tool, an algebraic stress model and a one-equation model for the dissipation rate tensor for low Reynolds number flows are considered, and the modeled quantities are compared with their directly computed counterparts. The data base from a direct numerical simulation of turbulent flow in a square duct is used to calculate all the terms in the Reynolds stress transport equations. The simulation of this complex turbulent flow was performed at a Reynolds number of 600 based on the friction velocity and the duct width. The distributions of the Reynolds stress budget terms along the wall bisector show similar dynamics to wall-bounded turbulent flows with one inhomogeneous direction. Budget terms in the vicinity of the corner demonstrate how transport and redistribution of energy and shear stresses between the Reynolds stress components takes place, promoting the turbulence characteristics of secondary flows of the second kind. The redistribution of energy by pressure velocity correlations can be explained by the low pressures at the cores of streamwise vortices. The data base is also used to evaluate a nonlinear turbulence model in its ability to accommodate the anisotropy of the Reynolds stress tensor in this flow. This anisotropy is known to be entirely responsible for the formation of the secondary flow in noncircular ducts and cannot be captured by linear models. Author

The present contribution reviews some of the recent progress obtained at our group in the direct numerical simulation (DNS) of compressible boundary layer transition. Elements of the different simulation approaches and numerical techniques employed are surveyed. Temporal and spatial simulations, as well as comparisons with results obtained from Parabolized Stability Equations, are discussed. DNS results are given for flat plate boundary layers in the Mach number range 1.6 to 4.5. A temporal DNS at Mach 4.5 has been continued through breakdown all the way to the turbulent stage. In addition results obtained with a recently developed extended temporal DNS approach are presented, which takes into account some nonparallel effects of a growing boundary layer. Results from this approach are quite close to those of spatial DNS, while preserving the efficiency of the temporal DNS. Author

Two new subgrid-scale models of turbulence are proposed on the basis of a 2nd-order velocity structure function model developed by Metais and Lesieur. They result from two different approaches aimed at preventing fluctuations at large scales from bringing about turbulent viscosity. Simulations of boundary layers at Mach 0.5 are presented showing that these two models make it possible to simulate the transition to a turbulent regime developed at moderate computational costs in appreciably different configurations (adiabatic plate and strongly heated dihedral). Vorticity transport concepts are applied to large eddy simulation (LES) techniques in two different contexts. In the first example, the LES equations of motion are reformulated by applying a spatial filter to the rotational rather than the momentum form of the Navier-Stokes equation, leading to the introduction of a subgrid-scale (SGS) vorticity flux tensor. A model originally developed using ensemble averaging is proposed and tested locally and instantaneously using simulations of full channel flow and a minimal channel calculation. The modeled and exact vorticity fluxes are found to generally agree, even for vorticity flux terms which are only present locally and instantaneously. The development of a vorticity transport based wall treatment using a deterministic vortex element approach is also outlined. Initial tests comparing the results of this approach to the zero pressure gradient and stagnation point boundary layer are compared to the Blasius and Falkner-Skan solutions and found to be in good agreement.

A new Subgrid scale (SGS) model used for Large-Eddy Simulation (LES) is developed by extending the scale-similarity hypothesis. Here a conventional Reynolds averaging is used instead of a test filter, resulting using the resolved (large scale) part of the Reynolds stress tensor. This resolved Reynolds stress (RRS) model, without any eddy viscosity assumption, is shown to properly reproduce the drain and backscatter partition of energy exchange between resolved and subgrid scales (for a channel flow at moderate Reynolds numbers). After assessing these properties by a priori tests (filtering DNS results), LES computations are carried out, determining the model constants by an analytical approach and a dynamic approach. In both cases, backscatter effects can lead to instabilities which are finally cured by introducing a transport equation for the SGS energy. This is felt necessary because when backscatter occurs, both SGS production and Kolmogorov dissipation are negative, so SGS energy must vanish, thus ending backscatter. Only a transport equation for the SGS energy can account for this energy conservation principle which is violated by dynamic approaches, that impose an average procedure. Slight discrepancies appear in the buffer layer which may be attributed to the insufficient resolution of streak structures in the spanwise direction. Thus, an adaptation for the buffer-layer appears to be the last obstacle to construct a model accounting for the most important physical properties required for SGS modeling and applicable for practical applications at high Reynolds numbers.

In this paper we report simulations of low to moderate Reynolds number turbulent pipe flow, obtained using a 3-D spectral code. Here we describe features of flows at Reynolds numbers Re = 2500 and 4000 and compare with available data. It is noted that simulations with periodic inflow/outflow boundary conditions do not reproduce the turbulent puff and slug flows found in spatially evolving transitional flows. The goal is to coordinate the use of this code with the currently performed SuperPipe experiments now underway at Princeton University. Author

The spatial evolution of disturbances in plane Poiseuille flow and zero pressure gradient boundary layer flow is considered. For disturbances governed by the linearized equations, potential for significant transient growth of the amplitude is demonstrated. The maximum amplification occurs for disturbances with zero or near zero frequencies. Spatial numerical simulations of the transition scenario involving a pair of oblique waves has been conducted for both flows. A fully spectral solver using a simple but efficient fringe region technique allowed the flows to be computed with high resolution into the fully turbulent domain. A modal decomposition of the simulation results indicates that non-linear excitation of the transient growth is responsible for the rapid emergence of low-frequency structures. Physically, this corresponds to streaky flow structures, as seen from the results of a numerical amplitude expansion. Thus, this spatial transition scenario has been found to be similar to the corresponding temporal one. In the boundary layer simulations the streaks are seen to break down from what appears to be a secondary instability. Author

It is argued that bypass transition on a flat plate can be interpreted as a consequence of the subcritical nature of the instability of the boundary layer, and that the minimum bypass Reynolds number should coincide with the one at which the turbulent layer relaminarizes spontaneously. This threshold is found by direct numerical simulation of a spatially periodic turbulent layer in which spatial growth is modeled by a linear normal velocity. The computed mean profiles and integral properties agree well with experimental results at the higher Reynolds numbers, but diverge from them at the lower ones. While experiments turn away from the turbulent correlations below Re(sub theta) approx. equals 300 - 500, the computations follow them until relaminarizing abruptly at Re(sub theta) approx. equals 200. The simulations use relatively small periodic computational boxes, holding only a few boundary

layer thickness, and it is argued that this provides enough feedback to prevent the transitional effects observed in experiments and to result in an absolute relaminarization threshold. The Reynolds number obtained in this way agrees with the onset of bypass transition in experiments with very high free stream turbulence levels, or with strong roughness tripping. Author

Results from a direct numerical simulation of turbulent mixing layer are presented. The flow evolves without shear and the mixing mechanisms associated with the turbulence are isolated. In the first set of simulations the turbulent mixing layer decays as energy is exchanged between the layers. In the second set, a forced mixing layer is simulated by continuously supplying energy to the higher energy side to maintain a stationary kinetic energy profile. Reynolds numbers based on the Taylor microscale of 28 and 38 are obtained in the decaying and forced simulations, respectively. The intermittency of the mixing layer is quantified by calculating the skewness and kurtosis of the velocity fields: results compare well with the shearless mixing layer experiments. Eddies of size of the integral scale (k(exp 3/2)/epsilon) penetrate the mixing layer intermittently, transporting energy and governing the growth rate. The scalar dissipation rate, a measure of the mixing, peaks in the mixing layer. The triple correlation models are applied to the inhomogeneous mixing layer and evaluated. The isotropic models tend to underpredict these correlations by as much as 60 percent while the more complicated anisotropic models are shown to be significantly more accurate. Both models for the pressure strain tensor are also shown to predict values that are incorrect by as much as 50 percent. Author

Direct simulations of two time-developing turbulent wakes have been performed. Initial conditions for the simulations were obtained from two realizations of a direct simulation of a turbulent boundary layer at momentum thickness Reynolds number 670. In addition, extra two-dimensional disturbances were added in one of the cases to mimic two-dimensional forcing. The unforced wake is allowed to evolve long enough to attain self-similarity. The mass-flux Reynolds number (equivalent to the momentum thickness Reynolds number in spatially developing wakes) is 2000, which is high enough for a short kappa(exp -5/3) range to be evident in the streamwise one-dimensional velocity spectrum. Several turbulence statistics have been computed by averaging in space and over the self-similar period in time. The growth rate in the unforced flow is low compared to experiments, but when this growth-rate difference is accounted for, the statistics of the unforced case are in reasonable agreement with experiments. However, the forced case is significantly different. The growth rate, turbulence Reynolds number, and turbulence intensities are as much as ten times larger in the forced case. In addition, the forced flow exhibits large-scale structures similar to those observed in transitional wakes, while the unforced flow does not. Author

A set of direct numerical simulations of temporally evolving incompressible plane wakes started from a variety of initial conditions have been performed. The intent is to explore the effect of initial conditions on the development of three dimensionality. It was found that the existence of an oblique disturbance at a streamwise wavelength equal to the two-dimensional subharmonic wavelength plays a very important role in the development of the wake. The Reynolds number and the presence or absence of longer wavelength disturbances were also found to be important at late times in the development of the flow. Disturbance phase was found to have an effect on the details of the structure of the wake, but has relatively little effect on the wake growth. Author

Direct numerical simulation of the tridimensional wake developing downstream from a NACA 0012 wing has been performed using the spectral element code NEKTON. The onset of instability in the wake of an infinite NACA 0012 wing is investigated. The first bifurcation is studied in a two dimensional configuration with a mesh obtained using the numerical experience with a two dimensional unstable cylinder wake. The second bifurcation accompanied by the onset of three-dimensionality is simulated on a three dimensional spectral element mesh obtained by extending the two-dimensional mesh spanwise. The onset of three-dimensionality is characterized by a deformation of the downstream and transverse velocity profiles in the spanwise direction and by the onset of an oscillating spanwise velocity. The critical Reynolds numbers are estimated for both bifurcations. The second bifurcation is shown to be characterized by a period doubling, i.e., the Strouhal frequency of the spanwise velocity is rather precisely equal to half the frequency of the transverse velocity oscillations. This result is in agreement with the numerical results of Karniadakis and Triantafyllou obtained for an infinite circular cylinder and confirms indirectly the experimental results of Williams-Stuber and Gharib showing that to obtain a Ruelle and Takens scenario in a wake, an external forcing is needed. Furthermore, simulations in a geometrically three-dimensional configuration of a finite wing are performed. The development of the tip vortex of a finite wing is investigated. Comparisons are made with available experimental results performed at low Reynolds numbers. The structure of the three dimensional flow is found to be in good agreement with experiments. The simulations are carried out at supercritical Reynolds numbers at which the wake is unstable. The wake oscillations and tip vortex oscillations are evidenced and shown to be characterized by roughly the same Strouhal frequency although the computations could not be pushed until relaxation of transients. The flowfield of an impinging jet is investigated numerically by means of the LES technique. The numerical scheme uses a high order upwind biased formulation for the advective transport. A localized dynamic evaluation of the Smagorinsky constant is employed to avoid an empirical tuning of this value. A critical problem is the formulation of open boundary conditions. The set of boundary conditions presented here allows both the entrainment of fluid into the computational domain as well as the exit of the large vortical structures typical for this flow problem. Direct and Large Eddy simulations of temporal evolving round jets at low Reynolds numbers have been performed by a second-order finite difference scheme in cylindrical coordinates. The simulations have shown the formation of longitudinal structures whose number increases with the Reynolds number. The role of these structures in the spreading of the jet and in the creation of small scales has been analyzed. LES models (Smagorinsky and dynamic models) permit to have satisfactory results with coarse grids. Author

The three-dimensional time evolution of a highly symmetrical vortex array is simulated using a Fourier pseudospectral method for Re = 1/nu = 2000 with an effective resolution of 1024(exp 3) collocation points (k(sub max) = 340). It is found that before the peak enstrophy is reached, there is a short stage when the local quantities increase sharply. The velocity derivative skewness and flatness values reach to 0.9 and 80 respectively. It is also found that during this interval, 6 vortex dipoles (at the origin) and 3 dipoles (at the pi/2 corner) collapse towards two separate vorticity null points. The coherent vortices break up afterwards followed by sharp decrease in local quantities possibly due to dissipation. The singularity analysis shows that maximum vorticity scales as (T - T(sub c))(exp -1) shortly before the break up. The temporal evolution of the width of the analyticity strip shows that delta approaches zero but reaches a minimum positive value and starts to increase. This suggests that the solution remains uniformly analytic similar to the viscous Burgers equation. Author

Direct Numerical Simulation is applied to a variety of small perturbations developing in a three-dimensional boundary layer. The basic flow is independent of the spanwise coordinate but incorporates a favorable and an adverse pressure gradient in the chordwise direction, similar to the leading-edge region of a swept wing. The edge velocity is analytically defined. Both Cross-Flow and Tollmien-Schlichting modes are amplified. Results focus on questions that are often open in three-dimensional transition-predictions codes, particularly 'e(exp N)' type codes. They include: non-parallel effects; choice of wave-vector; choice of propagation velocity and direction; and the effect of broad spectra, in either space direction and/or time. For this we survey a range of perturbations from pure waves to wave packets; the latter result from initial perturbations that are local in both space and time, and are arguably the richest type of disturbance. Quantitative results are offered for the validation of stability codes, and some are compared with Orr-Sommerfeld results. Author

Subcritical instability in the two-dimensional incompressible attachment-line boundary layer remains a topic of debate, after the apparently contradictory results of Hall and Malik (1986) on one hand and Spalart (1988) and Jimenez et al. (1990) on the other. Direct Numerical Simulation (DNS) results are presented, aiming at addressing this question. Extensive numerical experimentation has been performed and all results obtained suggest that the two-dimensional model equations describing leading edge boundary layer (LEBL) flow doe not support solutions growing subcritically in Reynolds number, although the nonlinear neutral loop is seen to bifurcate from its linear counterpart in a manner consistent with the predictions of the theory of Hall and Malik (1986). Nonlinear neutral loops have been obtained suggesting that the two-dimensional model LEBL flow is similar to the classical Blasius boundary layer in terms of the location, in parameter space, of the experimentally observed naturally occurring instability waves. Laminar-turbulent breakdown of a strongly decelerated Falkner-Skan-type boundary layer (Hartree-Parameter beta(sub H)=-0.18) is investigated by direct numerical simulations using the complete Navier-Stokes equations for three-dimensional incompressible flows. The numerical method is based on the so-called spatial model, and allows for simulations of spatially evolving three-dimensional disturbance waves in a two-dimensional growing boundary layer. Transition is initiated by 2-D and a pair of oblique 3-D waves, both with small amplitudes, excited periodically within a narrow disturbance strip at the plate surface. Their streamwise (linear and subsequent nonlinear) evolution resulting in the fundamental breakdown of laminar flow is simulated with

high spatial resolution. It is observed that the fundamental breakdown process under adverse pressure gradient is dramatically more complex than the well-known K-breakdown in the Blasius flow: In addition to the (upper) high-shear layer on top of the lambda-vortex, a (lower) characteristic high-shear layer is formed simultaneously in between neighboring lambda-vortices. This shear layer, induced by a secondary vortex system close to the wall, precipitates ultimate breakdown to turbulence. Finally, some results of preliminary studies on the effect of suction on boundary-layer transition are presented that demonstrate the great potential of spatial direct numerical simulations for applied transition research in flows of practical interest. Direct numerical simulations (DNS) of the Navier-Stokes equations are employed to explore the effects of suction holes on transition in a laminar flat plate boundary layer. The Navier-Stokes equations are cast in vorticity-velocity form. Periodicity is imposed in spanwise direction; all other spatial derivatives are discretized with fourth order compact differences. An explicit fourth order Runge-Kutta scheme is employed for the time-integration of the vorticity transport equations. Suction is applied through a row of holes aligned in spanwise direction. For low suction strengths, each hole generates a pair of stable streamwise vortices. When the suction strength exceeds a critical value, the vortices become unstable. For high suction strengths, vortex shedding occurs right at the suction holes. Our numerical findings agree well with experimental observations. Author

DIRECT NUMERICAL SIMULATION OF 2-D AND 3-D INSTABILITY WAVES IN A LAMINAR SEPARATION BUBBLE

ULRICH RIST and ULRICH MAUCHER *In* AGARD, Application of Direct and Large Eddy Simulation to Transition and Turbulence 7 p (SEE N95-21061 06-34) Dec. 1994

(Contract(s)/Grant(s): DFG-RI-680/1-1)
(AGARD-CP-551) Copyright Avail: CASI HC A02/MF A04

Direct Numerical Simulations of a laminar separation bubble are presented, where the bubble is generated by prescribing a locally decelerated free-stream velocity along a flat-plate. Controlled disturbances are introduced into the flow field upstream of the bubble by suction and blowing through the wall in order to study the linear and nonlinear stability characteristics of the flow. A number of generic cases with different two-dimensional (2-D) and three-dimensional (3-D) initial disturbance amplitudes are investigated: (1) a linear case; (2) a case subject to secondary instability (strong amplification of 3-D disturbances by resonance with a large amplitude 2-D wave); (3) a 3-D nonlinear case (interaction of two oblique waves); and (4) a nonlinear case combining the interaction of two oblique waves with a 2-D wave. Good quantitative agreement of the numerical results with (local) linear stability theory is observed throughout case (1) and for the initial disturbance development of the priming waves in the other cases despite the nonparallel base flow. For the nonlinear disturbance development development, however, unexpected results are obtained: Secondary instability is hard to distinguish from primary instability and apparently breaks down as soon as the priming 2-D disturbances saturate. However, the nonlinear mechanism identified in cases (3) and (4), is obviously much more likely to produce large amplitude 3-D disturbances necessary for the generation of a transitional laminar separation bubble. The mechanism leads to a nonlinearly saturated regime with reasonably turbulent mean-flow characteristics as well as longitudinal vortices in the reattachment zone. Author

The accurate prediction of shear layer transition plays an important role in the performance amelioration of modern aero-mechanical devices, since transitional shear layers are frequently observed on axial turbomachine blades and other low Reynolds number airfoils. In the present work some of the most famous existing turbulence models are used in order to analyze a large variety of well documented experimental transitional shear flows. Particular attention is paid to the estimation of the transition length and to the calculation of loss evolution inside the transition area. Finally interesting conclusions of the proposed analysis are summarized in the last part of the paper, where the behavior of several transitional blade shear layers is examined, applying the most reliable of the above tested turbulence models. Direct Numerical Simulation (DNS) of 2D and 3D lid-driven cavity flows have been performed. The results have been analyzed using Proper Orthogonal Decomposition (POD). POD has been applied to a 2D driven cavity at Reynolds number 22,000 and to a 3D at Re = 10,000. The POD-basis-functions have been computed using the so-called 'snapshot' method of Sirovich. The 2D basisfunctions are used for a Galerkin projection of the Navier-Stokes equations. This results in a relatively low (20 to 80) dimensional dynamical behavior, that shows (almost) the same dynamical behavior, in short and long term, as the DNS. Moreover, if the Reynolds number is set to 11,000, the 80-dimensional dynamical system has (almost) the same periodic solution as the 2D Navier-Stokes equations have at Re = 11,000. Author

Direct Simulations involve huge amounts of time dependent data and are expensive to run fully even on supercomputers. A thousand hours of CRAY to obtain valid results is in the order of things. Such costs can be significantly reduced by MIMD machines. To be able to analyze the computed results many and various visualization techniques are also essential. This paper presents work that was done at ONERA to parallelize a Navier-Stokes solver PEGASE and development of an interactive visualization tool at CIRA applied to numerical turbulent flow fields generated by the solver. This work was partly achieved within the framework of the European RACE/PAGEIN project which was aimed at demonstrating the feasibility of Direct Numerical Simulation techniques for future industrial developments, implying modern supercomputer technology, high performance computing networking and massive data transfers between vector and/or parallel supercomputers. The first part of this paper presents the essential characteristics of version 1.0 of PEGASE implemented on a vector machine, the second part describes modifications in algorithms and coding in order to implement it efficiently on the IPSC860 and on a PARAGON. Numerical results and comparisons in costs between the three machines are given. The third part

describes the graphics post-processing developed at CIRA.

Wind profiles in the atmospheric boundary layer are a very important parameter in the study of atmospheric exchange processes. A small laser Doppler anemometer was designed, constructed, and tested. The system consists of the laser Doppler anemometer mounted on a pedestal and controlled by a personal computer. A sine wave fitting computer program is used to get the wind velocities and wind direction for the selected levels. This sophisticated program can distinguish between cloud and aerosol signals and also uses the azimuthal angle-velocity for extracting the direction of the wind. D.R.D.

A NOVEL-HIGH-PERFORMANCE SYSTEM FOR RECORDING AND ANALYSING INSTANTANEOUS TOTAL PRESSURE DISTORTION IN AIR INTAKES
K. W. LOTTER and R.-D. SCHERBAUM *In* AGARD, Aerodynamic Engine/Airframe Integration for High Performance Aircraft and Missiles 16 p (SEE N93-13199 03-34) Sep. 1992

Instantaneous intake total pressure distortion parameters are generally used to assess aerodynamic intake-engine compatibility. Different distortion parameters are applied by the various engine manufacturers. Distortion boundaries are specified which are not to be exceeded in the intake during the whole flight regime. The quantification of those parameters is generally made in intake wind-tunnel model tests. In these tests the instantaneous total pressure is measured in the Aerodynamic Interface Plane (AIP) (a short distance upstream of the engine compressor face) by high-response pressure transducers, typically installed on an eight-arm rake with five probes on each arm. In the past, after having undergone the relevant signal conditioning process, the signals from the transducers were combined to the above-mentioned distortion parameters by the use of an analog computer. Later on, this was supplemented by limited digital analysis of the high-frequency signals. Because of the large amount of data, the digital analysis was only applied over a predetermined short time period. The evolution of high-performance digital data storage facilities combined with highspeed analog-digital conversion now allows a major step forward to longtime digital recording and analysis during intake distortion tests. The novel system that has been installed at MBB and successfully applied during various intake wing-tunnel test campaigns is described. Dynamic signals from up to 144 high-response differential transducers can be recorded. Individual control lines are used for sensing, power supply, and in-situ calibration. A specially configured computer system is used to control the signal frequency band, the number of signal channels, the control lines, and the sample rate. The computer is also used to control the storage of the digitized data on an advanced high density tape recording system that allows continuous recording of up to 1 hour on a cassette tape. The data rate for tape storage is as high as 107 Mbits/s. Parallel to this storage process it is possible to calculate, in an on-line real-time mode, the desired instantaneous distortion parameters using an analog computer. For recording times of up to 5 seconds for each data point, digital on-line analysis is also possible. The data can be displayed on a screen and are also plotted during the test, thus allowing the test engineer to react quickly and alter or adapt the test program. Typical results from tests with different intake models in various wind-tunnel facilities are presented. The effect of digitization rate and recording time on the error of the calculated instantaneous distortion parameters is shown. Author

(AGARD-CP-519) Copyright Avail: CASI HC A03/MF A04

This paper describes a project to develop and flight test a surface pressure measurement system on the UK Experimental Aircraft Program demonstrator aircraft. The paper begins with a brief description of the potential benefits of developing such a system. This is followed by the results and conclusions of development tests involving Wind Tunnel measurements and some preliminary Flight Trials. The installation details for the main Flight Test Trials are then described and the final results from the system are presented, compared with predictions based on previous Wind Tunnel measurements. The capability of the system to provide pressure distribution data of interest to the Aerodynamicist and integrated component loads for Flight Clearance purposes is demonstrated, and its usefulness as a Flight Testing technique is discussed. Several motion sensors of novel design have been developed during the past decade with the guided weapon or projectile market as the target user. In addition to technical performance requirements, all such sensors must be very robust with small size and mass, low power consumption and low cost. START is an angular rate sensor developed for this purpose. However, the guided munitions market has been very slow to evolve and new applications were sought in which the characteristics listed above, plus a very long operating and shelf life could be exploited. The field of image stabilization seemed promising and applications for use were followed up. The paper describes the characteristics of START which make it suited to this field and discusses some of the specific applications and the results achieved in tests of these equipments. Author

In the 1980's, Ring Laser Gyroscopes (RLG) displaced the mechanical (spinning wheel) gyroscope as the angular sensor of choice for navigation. While the RLG remains the standard navigation grade instrument, several other optical gyroscopes have recently appeared. The multi oscillator (or four-mode gyro) represents a new generation in laser gyroscopes. Systems based on this technology are now being delivered for use on commercial

and military aircraft. Another optical sensor, the fiber optic gyroscope (FOG) has been incorporated in inertial measurement units (IMU) and proved itself capable of AHRS (attitude and heading reference system) accuracy. This gyroscope should find many applications in aided navigation systems. Integrated FOG/GPS systems appear attractive as low cost navigators. This paper addresses technology involved in these optical gyroscopes and discusses their advantages and disadvantages in relation to present and future applications. Author

The SEXTANT Avionic company possesses a large spectrum of accelerometers for the different applications of Navigation. Since 1980, a constant concern about their adequacy to meet the need has led SEXTANT Avionic to develop micro-machined captors and accelerometers in particular. Many types of materials have been used and we expose the reasons for the choice of silicon in accelerometers destined for AHRS. The architecture of the accelerometer, the technologies used, and the functional modes are described. Then the actual performances of the different types of silicon accelerometers are explained, as well as their domain of application. In conclusion, perspectives of a longer term are given. Author

For further improvement of the turbine blade cooling process, the knowledge concerning the heat transfer in radial coolant channels has to be deepened. Due to rotation, the velocity distribution, as well as the turbulence structure and therefore the heat transfer, will be influenced. To carry out experimental data of the flow field within a rotating duct a non-intrusive continuous measuring system (Laser-Two-Focus) with an image rotator prism is presented. The design of the system is explained in detail. Problems of application are discussed and results of the first successful measurements compared with numerical results are presented. Piezoelectricity will be defined phenomenologically and discussed pictorially to underscore the distinction between single crystal piezoelectrics and the poled ceramics which form the basis for most practical sensor and actuator systems. The classical lead zirconate: lead titanate (PZT) family is the most widely used. Recent advances in the understanding of the conventional morphotropic phase boundary (MPB) compositions are discussed with particular emphasis upon the nature and the control of fatigue at high strain levels. Phase switching compositions in the lead zirconate stannate titanate PZSnT system exhibit very high switching volume strain, shape memory, and controlled induced piezoelectric response. Electrostrictors in the lead magnesium niobate: lead titanate and lead lanthanum zirconate titanate (PMN:PT and PLZT) families form most interesting spin glass states at lower temperature in which precise reproducible elastic strain may be induced by electric field. In PMN:PT the strain is free from aging and other domain related problems, the thermal expansion is very low, and these materials are ideal for very precise actuation. Polarization biased electrostrictors have exceedingly high induced piezoelectric d(sub 33), d(sub 31), and d(sub h) coefficients and can be used as agile transducers in which both the magnitude and phase of the response is under DC field control. Both spin glass and phase switching systems can be tuned in composition to optimize performance at 100 K and provide low power 'dial-a-displacement' capability. Recent advances in the fabrication of highly perfect thin films of PZT type compositions on silicon, by both vapor and liquid phase techniques provides a new high force electromechanical power source for microelectromechanical (MEMS) systems. The current status of the evaluation of electromechanical response in PZT, PMN:PT and PbSnZT thin films on silicon is briefly reviewed and possible applications in MEMS systems discussed. FIBER-OPTIC INTERFEROMETRIC STRAIN GAUGE FOR SMART STRUCTURES APPLICATIONS: FIRST FLIGHT TESTS
N. FUERSTENAU, D. D. JANZEN, and W. SCHMIDT *In* AGARD, Smart Structures for Aircraft and Spacecraft 6 p (SEE N94-11317 01-24) Apr. 1993
(AGARD-CP-531) Copyright Avail: CASI HC A02/MF A04

Initial flight tests of a fiber-optic strain gauge (OSG) based on a double-polarization Michelson interferometer with incremental readout via fringe counting were performed. The passive quadrature demodulation technique allows for balanced interferometer arms, exhibiting partial self temperature compensation. A bent reference (R) arm approach for the sake of isolation of the R-arm from the strain to be measured was tested for the first time. The sensor was surface adhered on a carbon fiber reinforced plastic plate which, in turn, was screwed to the main wing spar of a Cessna C207A aircraft. Strain was measured under different flight

conditions and compared to the readout of a conventional resistive strain gauge (ESG). Good agreement with the theoretical predictions as well as with the readout of the ESG was observed for short term (of the order of minutes) quasistatic strain measurements despite large vibration induced noise. The Fourier spectra of the time series exhibited also good agreement between ESG and OSG with respect to the dynamical response up to at least 250 Hz. The measurement range and stability of the present experimental setup is limited by polarization instabilities which partly are due to anisotropic transverse stress effects at the adhered fiber sections. Longer term dc strain measurements require carefully controlled isotropic adhesion conditions and miniaturized optomechanical components with improved mechanical stability. Author

BASIC PRINCIPLES OF FLIGHT TEST INSTRUMENTATION ENGINEERING, VOLUME 1, ISSUE 2 [INTRODUCTION GENERALE AUX PRINCIPES DE BASE DE L'INSTRUMENTATION DES ESSAIS EN VOL]

ROBERT W. BOREK, SR., ed. (National Aeronautics and Space Administration. Hugh L. Dryden Flight Research Center, Edwards, CA.) and A. POOL, ed. (National Aerospace Lab., Amsterdam, Netherlands.) Mar. 1994 295 p Flight Test Instrumentation Series

(AD-A282984; AGARD-AG-160-VOL-1-ISSUE-2; ISBN-92-835-0731-2) Copyright Avail: CASI HC A13/MF A03

Volume 1 of the AG 300 series on 'Flight Test Instrumentation' gives a general introduction to the basic principles of flight test instrumentation. The other volumes in the series provide more detailed treatments of selected topics on flight test instrumentation. Volume 1, first published in 1974, has been used extensively as an introduction for instrumentation courses and symposia, as well as being a reference work on the desk of most flight test and instrumentation engineers. It is hoped that this second edition, fully revised, will be used with as much enthusiasm as the first edition. In this edition a flight test system is considered to include both the data collection and data processing systems. In order to obtain an optimal data flow, the overall design of these two subsystems must be carefully matched; the detail development and the operation may have to be done by separate groups of specialists. The main emphasis is on the large automated instrumentation systems used for the initial flight testing of modern military and civil aircraft. This is done because there, many of the problems, which are discussed here, are more critical. It does not imply, however, that smaller systems with manual data processing are no longer used. In general, the systems should be designed to provide the required results at the lowest possible cost. For many tests which require only a few parameters, relatively simple systems are justified, especially if no complex equipment is available to the user. Although many of the aspects discussed in this volume apply to both small and large systems, aspects of the smaller systems are mentioned only when they are of special interest. The volume has been divided into three main parts. Part 1 defines the main starting points for the design of a flight test instrumentation system, as seen from the points of view of the flight test engineer and the instrumentation engineer. In Part 2 the discussion is concentrated on those aspects which apply to each individual measuring channel, and in Part 3 the main emphasis is on the integration of the individual data channels into one data collection system and on those aspects of the data processing which apply to the complete system. This paper deals with calibrations and uses of the five-hole probes for flow field survey. Two applications are given: one in transonic regime in the near slipstream of a powered propfan mounted on a half-model wing configuration and the other behind a generic submarine model at subsonic speeds. The acquired data have been analyzed in terms of flow angles, total and dynamic pressures and Mach number and velocity vector in a probe fixed coordinate system. These parameters were necessary in determining the flow field characteristics of the studied configurations which are presented and discussed. Author

(AGARD-CP-535) Copyright Avail: CASI HC A02/MF A04

This paper describes the optimization and systematic testing of a single component LDV system developed to perform measurements on the tests carried out to validate the performance of the system and on issues which are particular to high speed LDV applications. Particular emphasis is given to issues connected to the seeding of the flow such as the constraints on the selection of a seeding material and its sizing. Oblique shock wave traverses were performed to validate the selected seeding material and the developed seeding delivery system. These tests confirmed the monodispersity of the seeding in the wind tunnel test section and showed a reasonable particle response. The oblique shock traverse results are also compared to various particle dynamics models though the comparison is inconclusive. A series of supersonic laminar boundary layer traverses were also performed. These profiles are compared to the compressible flat plate boundary layer theory of Chapman and Rubesin and the validity of this theory in the current test conditions is demonstrated. The boundary layer measures are in good agreement with the theory, show good repeatability and do not display any signs of particle lag errors. Collectively, these experimental results clearly demonstrate the ability of the LDV system to perform accurate measurements in complex compressible flowfields. Author

Laser induced fluorescence (LIF) lidar is a promising technique for remote chemical detection and analysis for both hard targets

and extended atmospheric targets dispersed as aerosols or gases. The fluorescence spectra of the hard targets and of the aerosols and gases in the troposphere are primarily very broad and devoid of sharp line structure. When several species are present, the resulting overlapped spectrum is difficult to analyze. Interpretation of the multicomponent spectra of the lidar signal return is necessary for application of an UV lidar in a complex atmospheric environment such as a modern battlefield. Algorithms are described that were developed to process UV lidar fluorescence data and to analyze for chemical components. The analysis algorithms are based on factor analysis rank annihilation (FARA) techniques. Four methods are applied to lidar systems modeling and simulation analysis that contains both shot noise and sky radiance. The limitations are shown of UV lidar systems in terms of range, daytime/nighttime operation, and lidar system parameters. It was found that for situations in which several constituents are fluorescing and have close overlap, sky radiance limits nighttime use. Author

In order to profit from the advantages of a higher energy laser weapon for air defense tasks against aircraft, helicopters or missiles, a suitable laser source and a high-accuracy tracking and pointing system is required. The following publication describes a possible pointing and tracking concept for a laser weapon in order to compensate for the most important factors of disturbance and solve the problems faced when engaging airborne targets. In addition to describing the influence of the effects occurring during the laser beam propagation through the atmosphere and the methods for its compensation, this article will focus on the concept and the characteristics of the tracking and pointing system and its components, designed for a high energy laser weapon application. Finally, this publication gives a detailed description of the functional link of the essential subsystems and components of the pointing and tracking concept for high energy laser weapon applications. We report on the operational and performance of an integrated 1 meter adaptive optics system for compensation of atmospheric distortion of optical wavefronts. A visible artificial laser guide star (frequency-doybled Nd:YAG laser with wavelength of 0.532 microns) is used as the source for the reference wavefront. A shearing interferometer which uses a narrow optical bandwidth and has 500 subapertures is employed to sense wavefront distortion. These measurements are used to compute a conjugate wavefront to the distorted input light. The computed conjugate is then imprinted on a deformable mirror which consists of 500 square mirror segments. The effectiveness of the compensation is measured two ways: by imaging stars with a high resolution CCD camera in a narrow spectral bandwidth centered at 0.532 microns from which the point spread function is computed, or by collecting illuminator light reflected from a remote object with a photomultiplier tube. Atmospheric experiments are under way to test the performance of the integrated system. The results of these tests are very promising, yielding short-exposure stellar images which contain discernible energy at the diffraction limit of 0.1 arcsec, as well as a noticable improvement in the amount of light reflected from a remote target. Recent developments in laser anemometry have been used to design a three dimensional laser system which has been in operation at the CERT ONERA's T2 wind tunnel since December 1989: fiber optics (to lead the light between the source and the emitting optics), Fast FOURIER Transfer Doppler processors (to analyze the Doppler signals), high power transmission system (to provide color separation), digital control of displacement motors and real time operation (to move the measuring point during the run). This device works well for the short run times of the T2 wind tunnel, providing a good accuracy which allows 30 to 50 measurement points during 60 to 120 seconds of the test. After a complete description of the 3D laser velocimetry system, the present paper will develop some typical measurements which have been performed. For each case we will present some test results obtained under transonic conditions: shock wave probing (shape and location on the upper side of a 2D transonic model); and 3D velocity measurements in forward and backward scatter configurations with the wall approach for areas without good accessibility. In order to obtain the drag of a fuselage, a vertical plane located downstream of the model was measured with two devices: laser velocimetry in order to obtain the three components of velocity; and a pressure rake providing the static and total pressures. The combination of these measurements (pressure and velocity) allowed the calculation of the total drag of the 3D model. Author

This paper describes the second phase of an experimental program concerning the application of air bearings to small turbomachinery test rigs and small gas turbines. The first phase examined externally pressurized (EP) journal bearings, with a novel EP thrust bearing, for application to 'warm air' test rigs, and was entirely successful at rotational speeds in excess of 100,000 rpm. This second phase examined several designs of tilting pad-spiring journal bearings, one with a novel form of externally pressurized pad, but all using the original EP thrust bearing. The designs tested are described, including some oscillogram traces, for tests up to a maximum of 70,000 rpm; the most successful using a carbon pad-titanium beam spring arrangement. The thrust bearing which gave trouble-free operation throughout, is also described. The results of an original experiment to measure the 'runway speed' of a radial inflow turbine are also presented, which show that overspeeds of 58 percent above the design speed can result from free-power turbine coupling failure. AEROSERVOELASTIC STABILIZATION CONSIDERATIONS FOR POINTING AND TRACKING SYSTEMS
PETER Y. CHENG and RALPH E. LAMBERT *In* AGARD, Pointing and Tracking Systems 6 p (SEE N94-36616 12-18) May 1994
(AGARD-CP-539) Copyright Avail: CASI HC A02/MF A02

The high gain, wide bandwidth precision tracking/pointing systems used on advanced aircraft necessitate the consideration of aeroservoelasticity (ASE) early in the design process. Aircraft control systems are designed to meet stability, performance and, in the case of manned aircraft, handling qualities criteria defined by the Mil-Spec requirements. As digital controllers are introduced, airframes are made statically unstable, and as the push for increased dynamic response continues, the aeroservoelastic influences become increasingly important in the overall system performance. At times, the ASE considerations may dominate the rigid body control law design effort. This paper summarizes an approach to the ASE stabilization of a fighter aircraft when used as the integral part of a high bandwidth manual or automatic fire control tracking system. The same approach can be applied to standard manual control aircraft where a more thorough ASE analysis is desired. Author

A review of the turbomachinery preliminary design process is given with particular emphasis on axial and radial compressors. The review covers the selection of machine type, mean-line analysis and correlations, stagestacking calculations and the use of design charts and optimization techniques to find optimum values for design parameters. A comparison is made between the most successful correlations for endwall losses in axial compressors to highlight the different approaches that are possible. The preliminary design process provides an initial definition of the skeletal geometry of the blading and the annulus of the turbomachine. Turbomachinery design systems are then based on design by analysis, whereby the blading is assessed using CFD codes and is iteratively refined. A numerically based parametric blade geometry definition system makes the use of CFD considerably more effective. Examples of modern turbomachinery geometry definition methods involving Bezier surfaces and B-splines are described. Author

The aerodynamic design system at GE Aircraft Engines (GEAE) consists of many parts: throughflow, secondary flow, geometry generators, blade-to-blade and fully three-dimensional (3D) analysis. This paper describes each of these elements and discusses optimization and computer architecture issues. Emphasis is placed on those areas in which the company is thought to have special capability. (AGARD-LS-195) Copyright Avail: CASI HC A03/MF A03

This lecture advocates the direct use of three-dimensional flow calculations for turbomachinery design. The limitations of the usual quasi-three dimensional approach are discussed and it is shown that fully 3D calculations overcome the modelling limitations inherent in them. Fully 3D calculations also avoid the need to iterate between throughflow and blade to blade calculations. This leads to fewer routine operations (e.g. data transfers) being needed during the design process and hence more efficient use of the designer's time. With a flexible geometrical package, able to generate blade sections and transfer their geometry directly to a 3D data set, changes of stage geometry can be made in minutes. An outline of such a package is given. Modern 3D calculation methods, Ref(11), enable complete stage solutions. with adequate accuracy for design purposes, to be obtained in the order of I hour on a workstation. Hence several design iterations per day can be easily be performed for a single stage of a machine. An example used to design a very high pressure ratio (3:1) axial fan is given and discussed. The French Space Agency (CNES) started a study in late 1992 of an autonomous rover VAP (for Planetary Autonomous Vehicle). The aim of this study was to investigate multimission mobile platform design. The focus was placed on a martian mission for several reasons: (1) there is a very high scientific interest for Mars surface exploration leading to a better understanding of the solar system and Earth evolution; (2) roving on the planet is one mandatory and preliminary step before the conquest of the 'red planet' by manned mission; and (3) it is a necessary complement to fixed networks and sample return, in order to get data relevant to very large areas. The overall system concept including launch, cruise, deboost from Mars orbit, Mars atmosphere entry, and landing is not part of the study but is only kept in mind, as these phases of the mission induce several constraints. The main results of the study are given, showing the two possibilities: a large vehicle of 450 kg as the baseline and a smaller vehicle of 250 kg as an option. The various subsystems are described and the choices justified. The expected performances are summarized. Author

Techniques for the guidance, control, and navigation of unmanned ground vehicles are described in terms of the communication bandwidth requirements for driving and control of a vehicle remote from the human operator. Modes of operation are conveniently classified as conventional teleoperation, supervisory control, and fully autonomous control. The fundamental problem of maintaining a robust non-line-of-sight communications link between the human controller and the remote vehicle is discussed, as this provides the impetus for greater autonomy in the control system and the greatest scope for innovation. While supervisory control still requires the man to be providing the primary navigational intelligence, fully autonomous operation requires that mission navigation is provided solely by on-board machine intelligence. Methods directed at achieving this performance are described using various active and passive sensing of the terrain for route navigation and obstacle detection. Emphasis is given to TV imagery and signal processing techniques for image understanding. Reference is made to the limitations of current microprocessor technology and suitable computer architectures. Some of the more recent control techniques involve the use of neural networks, fuzzy logic, and data fusion and these are discussed in the context of road following and cross country navigation. Examples of autonomous vehicle testbeds operated at various laboratories around the world are given. Author

The aim of this work is to investigate the characteristics of mechanical erosion in a vertical sudden expansion turbulent two-phase flow. The flow field in an axisymmetric sudden expansion flow laden with round glass particles at 3 percent per volume and flowing in the direction of gravity was examined both experimentally and computationally. Velocities of particles and fluid were simultaneously measured at Re = 6 x 10(exp 4) using a single component laser Doppler anemometer and a burst peak detector which discriminates the amplitude of the Doppler bursts resulting from the two discrete phases. The test facility was refractive index matched, allowing measurement of the bar-U, V, sq bar-u, sq v and sq w components throughout the whole velocity flow field. Computations were performed using a Eulerian/Langrangian approach considering drag, lift and gravity forces acting on a particle as well as modelling of particle-dispersion by turbulence, particle-wall and particle-particle collisions. Mechanical erosion of the pipe wall was determined via an empirical formula, using the predicted impact velocities and angles. Author

The paper reports recent developments in the field of the interpretation of the form of the reflected wave during ultrasonic scanning of laminated plates. Defect analysis in laminated plates can be achieved by installing a threshold value on the amplitude of the reflected ultrasonic wave. If this threshold value has not been achieved, one considers that a defect is causing scatter and the location is registered as such. This is the most elementary form of measuring technique, although it does not provide more detailed information about the depth location of the defect. Nevertheless, it already provides some information, although rather 'binary'. On the used USIP 12 equipment (Krautkramer) a depth-measurement module was added allowing to establish the location of wave scatter through the thickness of the laminated structure. Recently, it has been suggested that the form of the reflected wave could yield some additional information on the types of defects. In particular, the frequency content of the reflected wave could be analyzed and be compared for different sorts of defects, thus allowing for a more accurate diagnostic of the defect and its significance. Advanced signal processing and pattern recognition techniques are therefore applied. Two Carbon/Epoxy laminated plates with several embedded defects have been manufactured and tested. Representative results will be given.

Damage detection in aircraft structures in-situ is important, especially with not visible defects in composite components for a variety of reasons. In the present paper a new technique based on the Acousto-Ultrasonic (AU) concept is introduced, but instead of extracting information from the externally generated pulsed wave, as with AU, the characteristics of waves reflected from defects are measured. In this way it was possible to identify and locate defected areas in honeycomb panels and thermoplastic carbon fiber laminates. The results were correlated with ultrasonic C-scans, and satisfactory agreement was obtained. The present is part of a major project aiming at the development of a fast inspection method for aircraft components during routine maintenance cycles. Author

IMPACT OF MATERIALS DEFECTS ON ENGINE STRUCTURES INTEGRITY [L'IMPACT DES DEFAUTS DES MATERIAUX SUR L'INTEGRITE DES STRUCTURES DES MOTEURS]

Apr. 1993 118 p In ENGLISH and FRENCH The 74th meeting was held in Patras, Greece, 27-28 May 1992
(AD-A267718; AGARD-R-790; ISBN-92-835-0711-8) Copyright Avail: CASI HC A06/MF A02

Engine failures due to materials defects are rare, but are still a cause for concern to both manufacturers and lifting authorities. In these circumstances it is recognized that the introduction of higher strength materials, new production routes and improved non-destructive evaluation methods may have significant implications for engine lifing and safety. The impact of inherent defects on present and future component manufacture and on aircraft engine operation is considered. Materials processing and control aspects are reviewed, placing particular emphasis on nickel and titanium engine disc materials. Variations in engineers', scientists' and lawyers' interpretation of the work 'defect' was perhaps the most significant point to emerge from the meeting; so much so, that a small group agreed to develop a definition, and when established recommend it as standard AGARD materials technology. For individual titles, see N94-37322 through N94-37331.

HISTORY AND PROGNOSIS OF MATERIAL DISCONTINUITY EFFECTS ON ENGINE COMPONENTS STRUCTURAL INTEGRITY

DAVID W. HOEPPNER *In* AGARD, Impact of Materials Defects on Engine Structures Integrity 8 p (SEE N94-37321 12-38) Apr. 1993

Ever since the development of aeroengines, 'defects' have been of significant concern to the assurance of structural integrity. Many of these issues have been the focus of recent Structures and Materials Panel (SMP) workshops and conferences. Although engine idealizations of materials being homogeneous, continuous, and 'free of defects' are invoked to make the complex issues of load, stress and strain, tractable, they were recognized as early as 1916, and later in the 1930's, as being oversimplistic and potentially in error. The epistemology of the role of discontinuities ('defects') in the design, selection, and lifing of critical aeroengine components is reviewed herein. Utilization of 'defect-free' and 'initiation' based fatigue criteria (as well as other time dependent failure modes such as creep, wear, etc.) have led to much success in the aeroengine industry. However, 'defects' also have led to numerous engine component failures in military and civilian aeroengines. And, as increasing demands are made on materials used in aeroengines, the role of 'defects' will, undoubtedly, become more important and critical. The history and prognosis of these issues is discussed with a review of on-condition lifing, defect-tolerant and damage-tolerant approaches, including, but not limited to, Engine Structural Integrity Program (ENSIP). The prognosis will suggest the need for the following: (1) development of increased understanding of the physics of failure processes of aeroengine materials; (2) integration of 'defect' considerations in the lifing methodologies from conceptual to detail design (the new paradigm of lifing); (3) assurance that knowledge of intrinsic materials behavior, including manufacturing specification and control, is a prime consideration in the defect-tolerant approach; (4) non-destructive inspection and evaluation should be one of many tools used to monitor and assure the state of the materials and should be a consideration in the lifing methodology at the earliest stage; (5) evaluation and integration of the role of extraneous influences, such as fretting, environmental attack, and the like, and how they are factored into the lifing procedure; and (6) development of consistent terminology with standardized definitions. Structural integrity of turbine disks must be guaranteed with a high safety level. The Engine Structural Integrity Program as contained in NIL-STD-1783 is aimed to enhance disk safety. A major design requirement is the implementation of the Damage Tolerance concepts by assessing the disk life in presence of defects. This paper illustrates the MIL-STD-1893 impact on turbine design as well as on material requirements, putting more emphasis on induced discontinuity features than on evolutionary ones. Targets for future developments in lifing procedures as well as in innovative materials are defined. taking into account possible differences in life management among NATO countries. Author

The application of powder metal (PM) superalloys in aircraft turbine engine rotating components is prompted by performance driven high strength and creep resistance requirements. Fine grain, precipitation strengthened nickel-base alloys such as IN100, Rene'95, and Rene'88DT meet these requirements up to operating temperatures in the 1200-1300F (649-704C) range. In addition to burst and deformation limits, design constraints include durability (fatigue) and damage tolerance (crack growth resistance) capability to insure reliability and safety. Fatigue life for these alloys can be influenced by inhomogeneities (inclusions) intrinsic to the microstructure as the result of processing, and by perturbations of the surface integrity during component manufacture and subsequent usage. Understanding of PM fatigue behavior and substantiation of life assessment methodology must appropriately recognize these potential influences. New testing, modeling, and analysis schemes are necessitated in engineering development programs addressing generation and validation of life prediction techniques for these materials. This paper outlines one approach to substantiating PM fatigue life prediction that attempts to recognize homogeneous fatigue initiation by incorporating probabilistic models and development testing methods that address material volume and component feature effects. Complications and limitations being addressed in ongoing work are discussed. Author

Fatigue is a statistical phenomenon with contributing factors which are statistical in nature too. Therefore probabilistic lifing concepts appear to be appropriate. Major components of any probabilistic lifting concept are: (1) microstructural characterization; (2) load history; and (3) material behavior. The results of any lifing model can only be as significant as the input data. This paper reviews some important aspects regarding input data which are necessary for the prediction of defect behavior by probabilistic models. Author

The Intelligent MCM Analyzer (IMCMA) is a software tool which allows the designer to concurrently assess the reliability of

an MCM design based on operational parameters. Traditionally, this type of assessment takes days to accomplish and is performed after the design phase. The Intelligent MCM Analyzer does not require the designer to be a thermal/reliability expert and gives an assessment in minutes depending on the complexity of the design and the speed of the computer. IMCMA assists the designer in achieving a robust design which will improve both quality and reliability. The software uses object-oriented data representation, a blackboard architecture and heuristic expertise to perform lower level reasoning associated with finite element thermal analysis techniques that are normally very tedious and labor intensive. A test case will be presented comparing results from IMCMA with the results from a general purpose finite element code. The ultimate payoff will be the manufacturers' ability to build higher quality, higher reliability MCM's at a lower cost. Author

Texas Instruments Incorporated (TI) developed the URDA processor design under contract with the U.S. Air Force Wright Laboratory and the U.S. Army Night Vision and Electro-Sensors Directorate. TI's approach couples advanced packaging solutions with advanced integrated circuit (IC) technology to provide a high-performance (200 MIPS/800 MFLOPS) modular avionics processor module for a wide range of avionics applications. TI's processor design integrates two Ada-programmable, URDA basic processor modules (BPM's) with a JIAWG-compatible PiBus and TMBus on a single F-22 common integrated processor-compatible form-factor SEM-E avionics card. A separate, high-speed (25-MWord/second 32-bit word) input/output bus is provided for sensor data. Each BPM provides a peak throughput of 100 MIPS scalar concurrent with 400-MFLOPS vector processing in a removable multichip module (MCM) mounted to a liquid-flowthrough (LFT) core and interfacing to a processor interface module printed wiring board (PWB). Commercial RISC technology coupled with TI's advanced bipolar complementary metal oxide semiconductor (BiCMOS) application specific integrated circuit (ASIC) and silicon-on-silicon packaging technologies are used to achieve the high performance in a miniaturized package. A Mips R4000-family reduced instruction set computer (RISC) processor and a TI 100-MHz BiCMOS vector coprocessor (VCP) ASIC provide, respectively, the 100 MIPS of a scalar processor throughput and 400 MFLOPS of vector processing throughput for each BPM. The TI Aladdim ASIC chipset was developed on the TI Aladdin Program under contract with the U.S. Army Communications and Electronics Command and was sponsored by the Advanced Research Projects Agency with technical direction from the U.S. Army Night Vision and Electro-Sensors Directorate. Multichip Module (MCM) packaging/interconnect technologies have seen increased emphasis from both the commercial and military communities as a means of increasing capability and performance while providing a vehicle for reducing cost, power and weight of the end item electronic application. This is accomplished through three basic Multichip module technologies, MCM-L that are laminates, MCM-C that are ceramic type substrates and MCM-D that are deposited substrates (e.g., polymer dielectric with thin film metals). Three types of interconnect structures are also used with these substrates and include, wire bond, Tape Automated Bonds (TAB) and flip chip ball bonds. Application, cost, producibility and reliability are the drivers that will determine which MCM technology will best fit a respective need or requirement. With all the benefits and technologies cited, it would be expected that the use of, or the planned use of, MCM's would be more extensive in both military and commercial applications. However, two significant roadblocks exist to implementation of these new technologies: the absence of reliability data and a single national standard for the procurement of reliable/quality MCM's. To address the preceding issues, the Reliability Technology to Achieve Insertion of Advanced Packaging (RELTECH) program has been established. This program, which began in May 1992, has endeavored to evaluate a cross section of MCM technologies covering all classes of MCM's previously cited. NASA and the Tri-Services (Air Force Rome Laboratory, Naval Surface Warfare Center, Crane IN and Army Research Laboratory) have teamed together with sponsorship from ARPA to evaluate the performance, reliability and producibility of MCM's for both military and commercial usage. This is done in close cooperation with our industry partners whose support is critical to the goals of the program. Several tasks are being performed by the RELTECH program and data from this effort, in conjunction with information from our industry partners as well as discussions with industry organizations (IPC, EIA, ISHM, etc.) are being used to develop the qualification and screening requirements for MCM's. Specific tasks being performed by the RELTECH program include technical assessments, product evaluations, reliability modeling, environmental testing, and failure analysis. This paper will describe the various tasks associated with the RELTECH program, status, progress and a description of the national dual use specification being developed for MCM technologies. Author

Preceding chapters have presented and discussed the objectives related to this large collaborative effort as well as relevant test techniques, modeling details and results in great detail. In 1988 an AGARD report had been published on the results obtained within the Core Program which represents the first of two parts of the AGARD Engine Disc Cooperative Test Program. The major issues treated within the present Supplemental Program were: to expand the initial Ti-6Al-4V data base to other titanium materials such as the Beta-processed IMI 685 and Ti-17 (again load controlled LCF tests were carried out on smooth and notched specimens as well as crack growth tests on compact tension (CT) and corner crack (CC) specimens under constant amplitude loading); to consider variable amplitude and spectrum load sequences that would be typical of compressor disc loading conditions; and to apply and evaluate fatigue crack growth modeling techniques based on the material/load cases of the Cooperative Test Program as mentioned above. Additionally microstructural and fractographic analyses were undertaken in order to relate macro crack growth behavior to microstructural features and intrinsic

material properties. In this final chapter, some main aspects and results are summarized. Conclusions and recommendations for future work are given. Author (revised)

(AGARD-CP-531) Copyright Avail: CASI HC A03/MF A04

New finite elements which allow for the analysis and optimization of adaptive structures are presented. Two finite elements accounting for integrated piezo-electric devices are formulated: a shell element for the analysis of shallow shell structures with piezo-electric polymers bonded to the surfaces and a truss element with an integrated piezo-electric ceramic. Test cases are presented to illustrate the potential of the finite elements. The shell element is used to compute the vibration excitation of a thin plate as well as the vibration control of a cantilever beam. The truss element is applied to the problem of optimal actuator placement in adaptive truss structures. For the solution of this problem, objective functions for the minimization of the control effort and the spillover energy are formulated. The second part is concerned with the finite element analysis of the behavior of shape memory alloys. A non-linear one-dimensional finite truss element and a non-linear beam element are used for the analysis of a composite beam with embedded shape memory alloy wires, of which the temperature is varied in order to tune the eigenfrequencies. A great number of gas turbine components gives cyclic symmetry properties which may be useful to analyze such parts. The resonance occurrences are numerous because of the different harmonics of the rotational speed. Shift phase characteristics between each periodic sector can be easily used to represent the complex system forces made of air flow distortions for instance. The aerodynamical forces are transmitted to the structure mainly by the blades. From this point, we note under some stationary pressure deviations, fixed in the space reference, that the airfoil undergoes pressure fluctuations during its revolution cycle. This stationary phenomena is periodic in the blade reference. It shows a forward or backward wave propagation whose frequency is determined within each frame. A couple of eigen modes, except under some particular conditions, can be found using cyclic symmetry conditions at exactly the same eigen value. The linear combination of both modes are used to analyze the wave propagation. Resonance conditions are shown in this paper and an assessment of an excitability factor has been introduced to reckon the potentially dangerous modes. This method is applied on a modal analysis of an impeller of a gas turbine engine designed by TURBOMECA. This step is pre-requisite to a complete simulation of dynamic responses incorporating dissipative functions and the aeroelastic coupling which mainly governs such a vibration phenomena. Author

The 3-D finite element method is used to simulate the structural effects of turbine blade impact on gas turbine engine structural casings and flanges, including both local effects and load transfer to the mounts. The analysis uses United Technologies' code WHAM to determine dynamic impact loads, and commercial codes MARC or MSC/NASTRAN to obtain transient stresses and distortions in the casings. The analysis is compared qualitatively and quantitatively to engine test results. Good correlation is obtained in predicting the observed failure. Author

Fatigue is an important consideration in structural design and monitoring of continued airworthiness of military aircraft. This Workshop titled 'An Assessment of Fatigue Damage and Crack Growth Prediction Techniques' provided a forum for an in-depth discussion of the correlation between in-service experience and results from analytical predictive models, specimen level tests, component tests, and full-scale tests. Additionally, it made possible an examination of the operating standards that different countries adopt with respect to various elements in the design process for assessment of fatigue damage. For individual titles, see N94-34582 through N94-34599.

MINER'S RULE REVISITED
W. SCHUETZ and P. HEULER *In* AGARD, An Assessment of Fatigue Damage and Crack Growth Prediction Techniques 10 p (SEE N94-34581 10-39) Mar. 1994
(AGARD-R-797) Copyright Avail: CASI HC A02/MF A03

In the first sections, the requirements to be met by hypotheses for fatigue life prediction (including those for the crack initiation and crack propagation phases) are discussed in detail. These requirements are shown to be different for 'scientific' and for 'industrial' fatigue life prediction. Aspects with regard to an assessment of fatigue life prediction hypotheses are discussed. The last section presents the results of a large cooperative program between IABG and several automobile manufacturers, in which Miner's Rule in several versions was assessed against spectrum tests with five different actual automobile components: forged steel stub axle; forged steel stub axle, induction hardened; sheet steel welded rear axle (front wheel drive car); cast aluminum wheel; and welded sheet steel wheel. Since up to 80 components each were available, and two different, but typical, automotive stress-time histories were employed, the assessment was very thorough, avoiding many of the drawbacks of previous assessments. It is shown that damage sums to failure were usually far below 1.0; they also depended on the component in question, the aluminum wheel resulting in the lowest damage sums to failure; the damage sums to failure where always lower for a mild spectrum than for a severe one; and the influence of spectrum variation was predicted best - among the hypotheses tested - by use of a recent proposal of Zenner and Liu. This paper reviews the capabilities of a plasticity-induced crack-closure model and life-prediction code to predict fatigue crack growth and fatigue lives of metallic materials. Crack-tip constraint factors, to account for three-dimensional effects, were selected to correlate large-crack growth rate data as a function of the effective stress-intensity factor range (Delta K(sub eff)) under constant amplitude loading. Some modifications to the Delta K(sub eff)-rate relations were needed in the near threshold regime to fit small-crackgrowth rate behavior and endurance limits. The model

was then used to calculate small- and large-crack growth rates, and in some cases total fatigue lives, for several aluminum and titanium alloys under constant-amplitude, variable-amplitude, and spectrum loading. Fatigue lives were calculated using the crack-growth relations and microstructural features like those that initiated cracks. Results from the tests and analyses agreed well.

Crack growth predictions for through and corner cracks in 7075-T651 plate under constant amplitude loading and corner cracks under two variable amplitude spectra were made using a 'black box' crack closure program. The results were then compared with experiment and various parameters adjusted to give the best match to the experimental results. The optimum parameters chosen will be used for subsequent blind predictions to be made on this material and different but related spectra. Author (revised)

To assess the consequences with regard to fatigue and damage tolerance of changes in operational usage, a simple means to quantify the relative severity of recorded load spectra is required. This paper describes the development and validation of the 'Crack Severity Index' CSI as a means to express the relative damage in terms of a 'crack growth potential' of stress spectra. The CSI is based on a crack-closure crack growth model and takes account of interaction effects by considering the shape of the spectrum. It is shown that the CSI-concept is a reasonably accurate method to compare the relative severity of maneuver dominated spectra in aluminum alloy structure. Author (revised)

The current state of crack growth prediction models for aerospace applications is reviewed with special reference to limitations and possible improvements. The present work aims at examining the different crack growth prediction models with reference to effective application for practical use (i.e. with the objective of identifying the experimental data necessary to apply the model) and at quantifying the reliability of the different models. Both crack growth prediction models currently used by aerospace industries and prediction methods under development within the scientific community are considered. An experimental program has been carried out to help achieve the objectives. Author (revised)

Experimental measurement and neural network based prediction of wind tunnel model empennage random pressures are discussed. Artificially generated neural network power spectral densities of surface pressures are used to augment existing data and then load an elastic finite element model to obtain response spectra. Details on the use of actual response spectra from flight test data are also discussed. A random spectra fatigue method is described which effectively combines buffet and maneuver loads into a time series based on aircraft usage data. A peak-valley damage analysis procedure is employed to compute the aggregate fatigue life of the structure based on five combined load time series information. Applications of the method as a continual learning tool for buffet response spectra is elaborated.

Fatigue life evaluation has been performed for flight-by-flight loaded coupons and real aircraft structural components made of 7075-T7351 using the local strain approach and a fracture mechanics based parameter. Results show that this approach can well compete with the traditionally used nominal stress approach. The advantages are a better understanding of material's fatigue behavior and a less experimental effort required for the determination of baseline data making the local strain approach interesting also for redesign within aircraft mid-life improvement updates. GROWTH OF ARTIFICIALLY AND NATURALLY INITIATING NOTCH ROOT CRACKS UNDER FALSTAFF SPECTRUM LOADING
R. SUNDER, R. V. PRAKASH, and E. I. MITCHENKO *In* AGARD, An Assessment of Fatigue Damage and Crack Growth Prediction Techniques 12 p (SEE N94-34581 10-39) Mar. 1994
(AGARD-R-797) Copyright Avail: CASI HC A03/MF A03

The paper describes an experimental study of notch root fatigue crack growth under FALSTAFF spectrum loading in an Al-Cu alloy. Crack growth rates were measured from crack size as small as 20 microns using optical fractography and replication technique. Fractographic measurements indicate similar scatter levels between notch root short crack and long growth rate data. This is in contrast to surface replica based measurements which are indicative of large scatter. Growth rate variation was noticed between multiple cracks initiating after different periods of natural crack formation. This is attributed to the influence of larger existing cracks on smaller cracks that appear later. In contrast identical artificially initiating cracks grew at a similar rate. Author

In this paper the methods used for calculating the fatigue life of metallic dynamic components in rotorcraft is reviewed. In the past, rotorcraft fatigue design has combined constant amplitude tests of full-scale parts with flight loads and usage data in a conservative manner to provide 'safe life' component replacement times. This is in contrast to other industries, such as the automobile industry, where spectrum loading in fatigue testing is a part of the design procedure. Traditionally, the linear cumulative damage rule has been used in a deterministic manner using a conservative value for fatigue strength based on a one in a thousand probability of failure. Conservatism on load and usage are also often employed. This procedure will be discussed along with the current U.S. Army fatigue life specification for new rotorcraft which is the so-called 'six nines' reliability requirement. In order to achieve the six nines reliability requirement the exploration and adoption of new approaches in design and fleet management may also be necessary if this requirement is to be met with a minimum impact on structural weight. To this end a fracture mechanics approach to fatigue life design may be required in order to provide a more accurate estimate of damage progression. Also reviewed in this paper is a fracture

mechanics approach for calculating total fatigue life which is based on a crack-closure small crack considerations. Author

THERMO-ACOUSTIC FATIGUE DESIGN FOR HYPERSONIC VEHICLE SKIN PANELS

KENNETH R. WENTZ, ROBERT D. BLEVINS (Rohr Industries, Inc., Chula Vista, CA.), and IAN HOLEHOUSE (Rohr Industries, Inc., Chula Vista, CA.) *In* AGARD, Impact of Acoustic Loads on Aircraft Structures 9 p (SEE N95-19142 05-71) Sep. 1994 (AGARD-CP-549) Copyright Avail: CASI HC A02/MF A03

Thermo-vibro-acoustic analysis and test of skin panels for airbreathing hypersonic vehicles is made for a generic vehicle and trajectory. Aerothermal analysis shows that impingement of the bow shock wave on the vehicle and engine noise produce high fluctuating pressures and local heat fluxes. Maximum temperatures will exceed 2700 F (1480 C) at the top of the ascent trajectory and engine sound levels will exceed 170 dB at takeoff. As a result, loads due to engine acoustics and shock impingement dominate the design of many transatmospheric vehicle skin panels. Author

A high-frequency theory (advanced statistical energy analysis (ASEA)) is developed which takes account of the mechanism of tunnelling and uses a ray theory approach to track the power flowing around a plate or a beam network and then uses statistical energy analysis (SEA) to take care of any residual power. ASEA divides the energy of each sub-system into energy that is freely available for transfer to other sub-systems and energy that is fixed within the sub-systems that are physically separate and can be interpreted as a series of mathematical models, the first of which is identical to standard SEA and subsequent higher order models are convergent on an accurate prediction. Using a structural assembly of six rods as an example, ASEA is shown to converge onto the exact results while SEA is shown to overpredict by up to 60 dB. Author

A VIRTUAL SENSOR FOR EVAPORATION DUCTS: THE IMPACT OF DATA UNCERTAINTIES

JOHN COOK *In* AGARD, Remote Sensing of the Propagation Environment 10 p (SEE N92-22790 13-46) Feb. 1992 Sponsored by Space and Naval Warfare Systems Command (AGARD-CP-502) Copyright Avail: CASI HC A02/MF A03

For this application, virtually sensed data is defined as the output from a combination of satellite based remote sensing instruments that have been blended with data from a numerical weather prediction model/data assimilation system and processed by an algorithm. Such a 'virtual sensor' is described to assess evaporation ducts over marine regions. Here, the sensitivity of four evaporation duct height algorithms are examined and the results are expressed in terms of the duct height error versus parameter error. The data used was generated parametrically so that a large variation of environmental conditions could be considered. The errors imposed on the data represent uncorrelated random errors associated with satellite based remote sensing inaccuracies. The study shows that, although the evaporation duct height algorithms have different genealogies, they have similar sensitivities. The conclusions represent a best case scenario because of the omission of some sources of error and the assumption of horizontal homogeneity in the near-surface refractivity field over a typical satellite sensor footprint. ON THE EFFECT OF EMISSIONS FROM AIRCRAFT ENGINES ON THE STATE OF THE ATMOSPHERE

U. SCHUMANN *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines 19 p (SEE N94-29246 08-25) Sep. 1993 Sponsored by DFG; BMFT; and Commision of the European Communities (AGARD-CP-536) Copyright Avail: CASI HC A03/MF A04

Emissions from aircraft engines include carbon dioxide, water vapor, nitrogen oxides, sulphur components, and various other gases and particles. Such emissions from high-flying global civil subsonic aircraft contribute to anthropogenic climate changes by increase of ozone and cloudiness in the upper troposphere, and by enhanced greenhouse effect. The absolute emissions by air traffic are small (a few percent of total) in comparison to surface emissions. However, the greenhouse effect of emitted water and of nitrogen oxides at cruise altitude is large in comparison to that of the same emissions near the earth's surface because of relatively large residence times at flight altitudes, low background concentrations, low temperature, and large radiative efficiency. At present, it appears that the emissions of nitrogen oxides have changed the background concentration in the upper troposphere in between 40 deg N and 60 deg N by 100 percent, causing an increase of ozone by about 20 percent. Regionally the observed annual mean change in cloudiness is of order 0.4 percent. The resultant greenhouse effect of changes in ozone and thin cirrus cloud cover causes a climatic surface temperature change of the order 0.01 to 0.1 K. These temperature changes are small in comparison to the natural variability. Recent research indicates that the emissions at cruise altitude may increase the amount of stratospheric aerosols and polar stratospheric clouds and thereby

may have an impact on the atmosphere environment, to a yet unknown degree. Air traffic is increasing by about five to six percent per year; fuel consumption grows by about three percent per year. Moreover, the climatic changes due to air traffic enhance other environmental problems originating, e.g., from anthropogenic carbon dioxide or methane emissions. Hence, air traffic induced emissions are of growing importance. This calls for the development of efficient and low-emission propulsion systems and other means to reduce the emissions. This paper surveys the state of knowledge and describes several items of results from recent and ongoing research. Author (revised)

Increasing complexity and sophistication of modern military sensor and weapon systems require a more accurate and timely description of the propagation environment for the entire electromagnetic spectrum. Active and passive remote sensing techniques deployed from the ground, airborne platforms, and satellites offer the greatest potential for producing the desired information in a timely manner. The symposium addressed: (1) sensing tropospheric refractivity using propagation measurements and various other remote sensing techniques; (2) ionospheric sensing techniques and interpretation of remotely sensed signatures; (3) sensing of aerosols and other atmospheric parameters important for the propagation of visible and infrared radiation; (4) techniques to measure winds, temperature, liquid water, and humidity in the lower atmosphere; and (5) measurement, inversion, and processing techniques. For individual titles, see N92-22791 through N92-22825.

REMOTE SENSING OF REFRACTIVITY STRUCTURE BY DIRECT RADIO MEASUREMENTS AT UHF
HERBERT V. HITNEY *In* AGARD, Remote Sensing of the Propagation Environment 6 p (SEE N92-22790 13-46) Feb. 1992 Sponsored by Office of Naval Technology
(AGARD-CP-502) Copyright Avail: CASI HC A02/MF A03

A method is presented that allows the base of a trapping layer to be determined directly from observations of signal strength on a UHF path in the southern California coastal area. The method uses long-term statistics of trapping layer thickness and refractivity gradient in the area. These statistics are used to compute radio signal strength as a function of the base height of the trapping layer using the Naval Ocean Systems Center Radio Physical Optics (RPO) model. The radio path selected is an over-water 148 km path with transmitter and receiver both located 30 m above sea level. The RPO results are used to infer the trapping layer base height directly from observations of received signal strength. This method was applied to a 40-day period of continuous signal strength recordings during which the trapping layer base height was known to vary considerably from near zero to about 1000 meters. Inferred base height versus time is compared to direct meteorological measurements of the base of the temperature inversion in the area of the measurements. Author

REMOTE SENSING OF THE EVAPORATION DUCT USING AN X-BAND RADAR
KENNETH D. ANDERSON *In* AGARD, Remote Sensing of the Propagation Environment 9 p (SEE N92-22790 13-46) Feb. 1992 Sponsored by Office of Naval Technology
(AGARD-CP-502) Copyright Avail: CASI HC A02/MF A03

Results from a unique analytical and measurement effort to assess low-altitude short-range radar detection capabilities in an evaporation ducting environment are presented. Although the measurement effort is ongoing, current results for unstable conditions validate propagation model predictions of reduced radar detection ranges within the radio horizon. In addition, discrepancies between measured and predicted radar data demand a close examination of both meteorological data and surface layer theory. At ranges near and beyond the horizon, radar detection capabilities crucially depend both on the surface layer refractivity profile and on the refractivity profile determined from upper-air observation. An empirical model to merge the surface layer with the mixed layer is discussed. Other discrepancies, which are thought to be caused either by inadequate surface layer modeling or by inadequate surface layer meteorological measurements, suggest the need for an improved surface layer model. Remote sensing of the evaporation duct by radar measurements is not a viable tactical tool. However, the combination of direct surface and upper-air meteorological measurements with remotely sensed radar measurements and with advanced numerical modeling capabilities does provide valuable insight for a better understanding of the atmospheric surface layer and its effects on low-altitude short-range radar detection. A high quality high frequency oblique ionosonde was developed for use in propagation research and associated studies of the ionosphere. The ionosonde is known as ROSE (Radio Oblique Sounding Equipment) and requires the connection of a specially designed enhancement to a commercially available chirp sounder receiver (RCS-5) manufactured by the BR Corporation in the USA. Two important features are brought about by the addition of this enhancement. First is an increase in the resolution of an ionogram by a factor of approximately three. This allows the fine structure in the ionospheric returns to be detected. Second is color coding of the ionogram according to the amplitude of the received signal. Detailed mode amplitude information and comparisons of the relative strengths of propagating modes can be achieved. Additional features which are provided include display handling and data storage facilities. Author

A small low cost digital ionosonde, the Digisonde Portable Sounder (DPS), was developed. It uses 500 microsecond, 10 percent duty factor, wide pulses for vertical sounding and 8.5 microsecond pulses for oblique sounding. Intrapulse coding and pulse compression techniques result in a 67 microsecond resolution for both waveforms. A new autoscaling technique for oblique ionograms inverts the oblique echo traces into midpoint electron density profiles that are modeled as a sum of quasiparabolic layers. Author

SENSING THE IONOSPHERIC REFLECTION CHANNEL WITH A SOUNDER
K. C. YEH (Illinois Univ. at Urbana-Champaign, Savoy.) and HAIM SOICHER (Army Communications-Electronics Command, Fort Monmouth, NJ.) *In* AGARD, Remote Sensing of the Propagation Environment 10 p (SEE N92-22790 13-46) Feb. 1992
(AGARD-CP-502) Copyright Avail: CASI HC A02/MF A03

A sounder was designed and constructed to probe the ionosphere for channel properties. The sounder must be capable of probing the ionosphere for wideband response. The implemented sounder consists of a transmitter located in Platteville, Colorado and a receiver located in Urbana, Illinois, separated by a ground distance of 1401 km. The transmitter and receiver are both PC controlled to sound the ionosphere at 6 frequencies selectable by the experimenter in the range of 5 to 15 MHz. The sounder can be commanded by a central PC in the laboratory to work in either the ranging mode or the probing mode. In the ranging mode, the time delay is measured; in the probing mode, the quadrature components (or amplitude and phase) are measured. Reported here are some experimental results obtained by using this sounder. Specifically, some properties of the time dependent transfer function of the channel are described. Author

ADAPTIVE REMOTE SENSING OF THE IONOSPHERE TO MINIMISE SPECTRAL INTRUSION
M. GALLAGHER and M. DARNELL *In* AGARD, Remote Sensing of the Propagation Environment 16 p (SEE N92-22790 13-46) Feb. 1992 Sponsored by Science Research Council; Roke Manor Research Ltd.; Siemens-Plessey Defence Systems; and RAE
(AGARD-CP-502) Copyright Avail: CASI HC A03/MF A03

Suggested here is a rationale for future remote sensing systems, using as an example an economical sounding system that employs standard radio system elements. The proposed rationale is based upon a generic architecture which can maximize the information gathered with the minimal active radiation of EM energy. The system described can passively monitor the output from proprietary 'chirp' sounders; it also has the additional capability of radiating its own sounding signals to complement the information gathered from passive monitoring. The active sounding takes the form of a segmented swept FM (SSFM) system. The profile of the sounding signal is produced digitally and can take a number of formats, which include simple linear FM ('chirp') as well as other profiles that are inherently tolerant to other specific propagation problems that exist within the ionosphere; for example, the effects of Doppler shift can be minimized through the use of hyperbolic FM. The sounding system adaptively uses sequences that can sound the channels allocated to the communication system as well as frequency ranges of high importance, such as regions near to the maximum usable frequency (MUF) and the lowest usable frequency (LUF). The intelligent and adaptive use of such scanning techniques means that spectrum pollution is minimized, while the information gathered is maximized. Author

A REVIEW OF VARIOUS TECHNIQUES FOR COMPUTERIZED TOMOGRAPHIC IMAGING OF THE IONOSPHERE
T. D. RAYMUND *In* AGARD, Remote Sensing of the Propagation Environment 10 p (SEE N92-22790 13-46) Feb. 1992
(AGARD-CP-502) Copyright Avail: CASI HC A02/MF A03

By using some new tomographic techniques for ionospheric electron density imaging, it may be possible to inexpensively (relative to incoherent scatter techniques) image ionospheric electron density in a vertical plane several times per day. Here, the basic geometry of the problem is reviewed and various techniques are discussed. The satellite-receiver geometry used to measure the total electron content causes the data to be incomplete; that is, the measured data do not contain enough information to completely specify the ionospheric electron density distribution in the plane between the satellite and the receivers. Most of the proposed techniques include some method designed to overcome this problem. Applications of these techniques made to simulated and real data and the results are compared and discussed. (AGARD-CP-502) Copyright Avail: CASI HC A03/MF A03

Applications involving radio waves propagating through the ionosphere are subject to errors due to the effects of the medium. For several of these effects, the electron content along the propagation path is a key parameter. At high altitudes, steep gradients in electron content resulting from electron density variations in the vicinity of the ionospheric trough are of particular importance. Described here are two methods of mapping electron content and electron density in the sub-auroral ionosphere over northern Europe. The first experiment yields measurements of differential carrier phase from which estimates can be made of the total electron content as a function of latitude for each pass of the NNSS satellites monitored. Calibration to obtain absolute values is achieved using spot data from a co-located receiving system for Global Positioning System (GPS) satellites or by means of ionosonde foF2 values and a slab thickness model. Results are presented illustrating behavior of the ionospheric trough. A second experimental campaign used the simultaneous observations of the NNSS satellites at four stations covering a latitudinal range of some 8 degrees. The resulting measurements of electron content from some 30 satellite passes were used in a reconstruction algorithm to map the electron density on a two dimensional grid. The potential usefulness of tomographic techniques in ionospheric sensing is discussed in light of the results obtained. Author

Very Long Baseline Interferometry (VLBI) is sensitive to integrated effects along the line of sight. Provision of high quality information about the characteristics of the propagation environment is, therefore, inherent to this technique. The way this technique is generally used also enables the determination of these characteristics with a high time resolution, which makes it useful for the study of irregularities in the medium. Described here are the possibilities and limitations of this technique for ionospheric sensing and sensing of tropospheric refractivity. This technique is compared to some others used to derive the same information. The requirements for data handling and processing techniques are described, as well as the available 'tools'. Author

One-dimensional interferometric radar systems with receiver baselines directed in magnetic north-south and east-west directions were used to study the anisotropy and inhomogeneity characteristics of ionospheric irregularities. In equatorial electrojet aspect sensitivity measurements conducted at Jicamarca, angular spectrum widths as small as approx. 0.05 degrees were resolved. The cross field structures and dynamics of electrojet irregularities were investigated using an interferometric imaging technique. Author

Rigorous analyses of complex propagation problems necessitate the use of complete electromagnetic field expansions in three dimensions, the imposition of exact boundary conditions and the application of precise analytical procedures. The complete modal expansion of the horizontally and vertically polarized electromagnetic fields (Transverse Electric and Transverse Magnetic) consists of the radiation term, the lateral wave term, and the trapped waveguide modes. The tangential components of the electric and magnetic fields must be continuous at each of the interfaces of the irregular stratified media. Since the field expansions do not necessarily converge uniformly on the irregular boundaries of the stratified media, Green's theorems should be used to avoid interchanging orders of integration (summation) and differentiation. The 'full wave' procedures are used to convert Maxwell's equations into sets of generalized telegraphists' equations for the forward and backward propagating wave amplitudes. Author

SENSING OF ELF SIGNATURES ARISING FROM SPACE VEHICLE DISTURBANCES OF THE IONOSPHERE
JACK Y. DEA (Naval Ocean Systems Center, San Diego, CA.), WILLIAM VANBISE (Magtek Lab., Reno, NV.), ELIZABETH A. RAUSCHER (Magtek Lab., Reno, NV.), and WOLFGANG-MARTIN BOERNER (Illinois Univ., Chicago.) *In* AGARD, Remote Sensing of the Propagation Environment 11 p (SEE N92-22790 13-46) Feb. 1992
(AGARD-CP-502) Copyright Avail: CASI HC A03/MF A03

Observations of Extremely Low Frequency (ELF) signatures during exit or reentry of space vehicles through the ionosphere are presented. The two modes regularly observed gave signals that peaked at 5.6 Hz and 11.2 Hz. The evidence points to the lower ionosphere, i.e., the D- and E-layers, as the generator of the signals. The measurements were performed using ground-based multi-turn coil sensors located in Reno and San Diego. The nature of these signals is unclear at present but it is surmised that we are detecting either the evanescent fields of hydromagnetic waves traveling in the ionosphere or the oscillating geomagnetic field associated with these hydromagnetic waves. Observations of broadband ULF signals before and after an earthquake are presented. The particular quake in question was the Upland quake of 17 Apr. 1990, which was centered 200 km north of San Diego. The signals were detected with the vertically oriented search coil sensor and not with the horizontally oriented sensors, which suggests a disturbed ionosphere as the most likely source of these signals. The large prequake ULF activity, the rapid decay of ULF activity after the quake, and the absence of any geomagnetic storms indicate a good correlation of the ULF activity with the Upland quake. An interpretation of radio observations of seismic activity is presented and extended to earthquake precursor studies. Author

A review is presented of past efforts to determine atmospheric extinction from single-ended lidar measurements of backscatter, and the assumptions made concerning the backscatter/extinction relationships. The degree to which the aerosols within the convectively mixed atmosphere can be expected to be horizontally homogeneous is also discussed. The conclusions are that unless the extinction/backscatter relationship is known, or that the atmosphere is horizontally homogeneous over the propagation path, the accuracies of extinction coefficients determined by a single-ended lidar cannot be assured. Lidar (optical radar) is a generally accepted technique which is used for remote sensing of atmospheric properties over ranges of kilometers to within a few microseconds. Different inversion techniques used to derive the required information from the lidar signal are discussed. The lidar properties determine which kind of information can be obtained. An overview of results obtained with two different lidar systems is presented. The results include the assessment of the systems, long term studies of the vertical infrared structure of the atmosphere, and fast dynamic processes. D.R.D.

A technique was developed by which lidar (optical radar) returns can be used to adjust simultaneously observed/modeled aerosol size distributions to represent existing atmospheric conditions. The technique was used to evaluate the U.S. Navy Maritime Aerosol Model (NAM) and the U.S. Navy Oceanic Vertical Aerosol Model (NOVAM). The evaluation of NOVAM indicated that, when scaled to visibility, good agreement exists between the lidar scaled extinction and backscatter coefficients and the predicted profiles. While adjustments of the NAM aerosol number densities can be made to match the modeled S(R) profiles to that measured by lidar in the first few meters above the surface of the ocean, the large adjustments for low wind speed indicates that the modeled aerosol size distribution shape near the ocean surface may not be correct. To characterize Earth/space communication links, the Jet Propulsion Laboratory's (JPL's) Radiowave Propagation Program supports a number of propagation studies. Low-availability satellite links and their propagation vagaries at Ka and millimeter-wave bands constitute a major effort within this program. Since 1987, this program has funded the Wave Propagation Laboratory (WPL) of the National Oceanic and Atmospheric Administration (NOAA) to conduct multiple-frequency radiometric observations of the

atmosphere. Measurements of atmospheric emission and attenuation at 20, 31, and 90 GHz at different locations are presented. Single-station and joint-station statistics are derived. A linear regression scheme for the prediction of fade statistics in one channel using fade data from the other two channels is presented. Author

The nature was studied of atmospheric refraction and criteria was developed when refraction may cause errors in tank gunnery in deserts. Refraction can be remotely sensed as a function of time through point to point measurements of the elevation of a distant object relative to the atmospheric neutral events that occur approximately 1/2 hr before sunset and 1/2 hr after sunrise. The vertical position change of a distant object can be measured using either another object close enough to the observer that effects will be minimal (thus providing a fixed reference point) or a theodolite that has its own internal reference through the leveling bubble. Extensive measurements were made of diurnal variations in elevation of distant objects at White Sands Missile Range (WSMR), NM. Lessons learned from these experiments include accounting for numerous potential error sources when taking readings using theodolites and the photographic techniques necessary to cope with changing light levels and atmospheric turbulence effects. Measurements were made at other locations that exhibit similar vertical shifting characteristics. A surface energy budget model was developed to predict refraction situations based on meteorological measurements. Author

A neural network scheme for retrieving remotely sensed vertical temperature profiles was applied to observed ground based radiometer measurements. The neural network used microwave radiance measurements and surface measurements of temperature and pressure as inputs. Because the microwave radiometer is capable of measuring 4 oxygen channels at 5 different elevation angles (9, 15, 25, 40, and 90 degs), 20 microwave measurements are potentially available. Because these measurements have considerable redundancy, a neural network was experimented with, accepting as inputs microwave measurements taken at 53.88 GHz, 40 deg; 57.45 GHz, 40 deg; and 57.45, 90 deg. The primary test site was located at White Sands Missile Range (WSMR), NM. Results are compared with measurements made simultaneously with balloon borne radiosonde instruments and with radiometric temperature retrievals made using more conventional retrieval algorithms. The neural network was trained using a Widrow-Hoff delta rule procedure. Functions of date to include season dependence in the retrieval process and functions of time to include diurnal effects were used as inputs to the neural network.

The atmosphere of the earth is a very complex system covering a wide range of interacting scales. The concept of stability is applied to subsystems thereof where the quantities involved in a stability analysis depend on the particular question to be answered. But all stability considerations share a common basic structure. After giving a short account to the nature of stability investigations, some examples of stability related atmospheric phenomena are presented which are relevant for flight operation. Finally, the impact of atmospheric instability on aircraft performance with special regard to flight safety is illustrated. Author

Clear air sensing radars, which are used for wind sounding from surface platforms, are now widely deployed. They are usually designed to measure the Doppler sensed movement of clear air refractive index inhomogeneities, but they also provide an excellent tool for sensing ice and water particles in clouds. These radars usually have a very low detection threshold and long averaging time so that size distributions of particles as small as 100 micrometer diameter with mean vertical fall velocities (V sub f) as small as 0.2/ms can be accurately measured. Data is presented from two events in which clouds form, intensify, and finally produce precipitation. Height profiles are displayed and analyzed as ZRV sub f plots vs. height, where Z is the radar reflectivity factor, R is liquid flux (rain), and V sub f is the mean fall velocity in quiet air derived from the radar measured vertical velocity. It is shown how these radars can provide (1) cloud layer structure above lower overcast; (2) height profiles of liquid mean drop size; (3) the ice water transition level compared with the 0 deg isotherm; (4) height profiles of rain rate; and (5) inferences about the identity of hydrometeors vs. height. Throughout the last two decades, dramatic changes have been taking place in the field of radar meteorology. The effects of modern digital signal processing techniques should be especially considered. These new technologies present new opportunities in the weather radar research arena. Real-time processing is at present the key problem in this field, because by nature, meteorological targets are distributed in space and occupy a large portion of the spatial resolution cells observed by radar. For this reason, meteorological radars require high data rate recording and effective real-time processing. To solve the data handling and processing problems for weather surveillance radars, a method was initiated. The method makes use of a 'Framing based Radar Data Analysis'. The method shows great potential in the field of rain cell modeling and ground clutter suppression. The first verifications were performed using the off-line experimental data obtained from the operational Delft radar SOLIDAR. Author

Canada has undertaken long-term research program to study winter storms in coastal regions, with the objectives of improving their forecast and understanding their embedded mesoscale features, rapid intensification, and microphysical conditions associated with aircraft icing. In cooperation with the Atmospheric Environment Service of Environment Canada (AES), the National Research Council (NRC) Twin Otter and Convair 580 aircraft have been instrumented to measure the motion and thermal structure of the atmosphere and the microphysics of cloud and precipitation. The aircraft have been flown in two Atlantic Storms projects in conditions that pilots usually attempt to avoid. Examples of the hazardous conditions encountered in these research flights are presented in this paper, along with supporting air motion and microphysics data recorded aboard the aircraft. Incidents of airframe icing, turbulence, strong winds and wind shear serve as an introduction to the more detailed treatment of these subjects by subsequent lecturers. Other related subjects covered include research reduced visibility and on-ground icing of aircraft. Information is presented on recent developments in instrumentation for the early recognition and warning of hazardous flight conditions. The paper concludes with a look to the future for coping with winter storms in Canada, including planned research field programs. Author

Extreme temperatures, both hot and cold, can severely restrict the ability of aircrew and support personnel to accomplish their missions. Under emergency conditions of bail-out, ejection, and ditching of fixed or rotary-wing aircraft on land or in water, the survival rate of aircrew and passengers is also affected by the intensity of thermal stress experienced and the duration of exposure to the thermal stress. This has all recently been borne out by the experience of intense air operations in the Gulf War. This symposium reviewed the operational conditions experienced under extreme hot and cold weather. The papers presented at this symposium highlighted recent advances in thermal physiology, clothing sciences, personal flying equipment, and microclimate cooling. Emphasis was placed on the potential applications of these advances in situations where thermal stress may confound the efficient achievement of mission objectives. Animals have two main methods of adjusting their body temperature. Poikilothermic animals adjust it to the existing ambient temperature, temperature, whereas homoiothermic animals keep temperature at a relatively constant value which is frequently above the ambient temperature; thus, temperature; thus, they able to stay in contrast to poikilothermic animals whose metabolic processes slow down increasingly due to van't Hoff's rule when ambient temperatures are when ambient temperatures are low, rendering sometimes even resulting in low-temperature rigidity. This, however, enables them to survive for a longer period of time in case of a lack of food and/or cold spells. Hibernating animals are something in between. In times of food shortage and in the period of cold weather, they reduce their metabolic processes and lower their body temperature. Without a doubt, man is part of the group of homoiothermic organisms. However, when having a closer look at homoiothermic organisms, it becomes obvious that their body temperature is only constant as far as the body core and the vital organs are concerned - there are fluctuations in the temperature of the extremities, i.e., the outer parts of the body, which are mainly induced by the environment. Consequently, the tissue of these regions of the body is subject to changes in temperature which may be considerable without resulting in permanent damage. Findings, mainly obtained from transplantation medicine, have shown that the organs of the body core need not be damaged irreversibly either, if their temperature is lowered for several hours - on the contrary, they can even be preserved this way for a limited period. Pilots of modern fighter aircraft are endangered by high G-forces, loss of situational awareness, and spatial disorientation. In order to prepare aircrew for these factors, ground based training facilities simulating some aspects of the relevant phenomena are used. The human centrifuge has proven to be rather effective in increasing G-tolerance, especially in conditions of high onset rate. Unrealistic simulations caused by the small radius of rotation in centrifuges can generate disturbing vestibular stimulation. During the development of the human centrifuge at the Netherlands Aerospace Medical Center an investigation was undertaken to find methods to suppress these detrimental effects. Smoothing of centrifuge motion and a realistic, computer-generated outside-vision system proved to be effective measures. Realistic target tracking and a cockpit-like environment are factors which enhance transfer of training. Author

These proceedings include the technical evaluation report, the opening address, and 36 papers of the symposium. The theme of the symposium was the fight against infectious diseases, mainly the vaccine-preventable ones, and the study of inhalent allergic diseases. Enormous development in the last few years has allowed us to understand and prevent many pathological conditions, whereas the setting up of laboratory tests has allowed us to monitor with great precision the immune function which may be depressed by the environmental stimuli to space or military flight. Lastly, the development of military and civilian air travel, which favors the spreading of infectious and parasitic diseases, requires the setting up of correct prophylactic measures. For individual titles, see N93-11284 through N93-11318.

Depression of lymphocyte response to mitogens in cosmonauts after spaceflight was reported for the first time in the early seventies by Soviet immunologists. Today we know that depression of lymphocyte function affects at least 50 percent of space crew members. Investigations on the ground on subjects undergoing physical and psychological stress indicate that stress is a major factor immune depression of astronauts. This despite the fact that weightlessness per-se has a strong inhibitory effect of lymphocyte activation in-vitro. Although the changes observed never harmed the health of astronauts, immunological changes must be seriously investigated and understood in view of long duration flights on space stations in an Earth orbit and to other planets like Mars and the Moon. MECHANISMS OF IMMUNE FAILURE IN BURN INJURY

BRIAN G. SPARKES *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 12 p (SEE N93-11283 02-52) Apr. 1992

The burden on military medical services in handling burn casualties is daunting as all physiological systems will become affected. Severe burns in a battlefield setting have a very low salvage rate, to a great degree because of the immune failure which invariably develops. Evaluations of responses of lymphocytes taken from burn patients over several weeks following the burn (greater than 30 percent TBSA), have revealed that the immune failure which follows thermal injury involves T cell activation events. Interleukin 2, which is normally produced by activated T lymphocytes, is very poorly produced by cells cultivated in vitro taken from non-surviving patients, whereas some production continues, although at below normal levels, in patients who ultimately survive their injury. IL2 exogenously added to lymphocyte cultures enhances the proliferation of cells from surviving patients but gives no such help to cells from nonsurvivors. The TAC portion of the IL2 receptor (IL2R alpha), expressed on the T cell surface, appears to be responsible for this difference, as the number of lymphocytes able to express ILR2 alpha falls post-burn. A lipid protein complex (LPC) produced in skin by burning has been shown to inhibit the immune response in vivo and the growth of IL2-dependent lymphocytes in culture. Cerium nitrate, applied topically to the burn patient, is thought to fix the LPC in the burn eschar and prevents its entry into the circulation. In a study of 10 patients, bathed in cerium nitrate, some T lymphocyte activities were found to be in the normal range rather than suppressed. Such a treatment promises to be useful in improving chances of survival in severe burn injury. Author

Hepatitis B is a parenterally and sexually transmitted disease of global importance. The disease runs more frequently a subclinical and anicteric course, with a significative rate of cases that become chronic. Chronic hepatitis may progress to cirrhosis or cancer. The strategies by which Hepatitis B can be diminished and eventually eliminated are: immunization, measures to prevent exposure to infective blood or blood derivatives, and education (in particular awareness that hepatitis B is a sexually transmitted disease). (AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

Viral hepatitis and its acute and chronic complications continue to pose significant threats to the readiness of military personnel. Knowledge about the specific viral agents and their routes of transmission are important in developing prevention strategies. A recent analysis of hepatitis in the U.S. Navy for the period 1975-1984 is reviewed. In order to better characterize the risk of viral hepatitis among Air Force personnel, a comprehensive review of inpatient and quarters data for hepatitis A, B and 'non-A, non-B' were reviewed from Air Force medical treatment facilities worldwide for the period 1980-1989. Following a discussion of the study methodology, preliminary data and hepatitis type-specific demographic risk variables are discussed. Preliminary results from a hepatitis serosurvey (A, B, and C antibody with use of a supplemental validating assay) of the subset of the study cohort who are currently on active duty are briefly reviewed. The incidence rate of hepatitis A is 3(-6)/1000 per month of stay in a developing country in unprotected travelers. Trampers and other persons feeding themselves under bad hygienic conditions have a rate of 20/1000. In many industrialized countries, persons below the age of 50 years have a seroprevalence rate of anti-HAV less than 20 percent. Hepatitis A morbidity and mortality in travelers is far greater than the one of any other vaccine preventable infection in travelers, with the exception that hepatitis B shows a slightly greater mortality in expatriates. Future studies will determine the role of hepatitis C and E. Typhoid fever shows an incidence rate of 0.3/1000 in foreigners on the Indian subcontinent, and in many parts of North and West Africa, excluding Tunisia, in other parts of the third world it is tenfold lower. In poliomyelitis, tetanus, diphtheria, cholera, rabies, and Japanese encephalitis, the incidence rate is greater than or equal to 0.002/1000. Author

Viral hepatitis type B is a major worldwide public health problem. Infection with the hepatitis B virus (HBV) may progress to chronic liver disease including chronic active hepatitis, cirrhosis, and hepatocellular carcinoma. Moreover, it has been estimated that between 200 and 300 million individuals in the world are chronic carriers of HBV. The availability of safe and effective vaccines allows the establishment of immunization programs aimed at the elimination of hepatitis B and the reduction of morbidity and mortality due to its sequelae. The topics covered include the following: (1) vaccines against hepatitis type B; (2) safety, immunogenicity, and efficacy of hepatitis B vaccines; (3) strategies for control of hepatitis B by immunization; and (4) hepatitis B vaccination in Italy. By the year 2000, a cumulative global total of 30 to 40 million men, women, and children are projected to have been infected with HIV. This will present a 3 to 4 times increase of the present total. Currently, it is estimated that about 5000 persons are newly infected daily. Worldwide, the predominant and increasing mode for transmission is by heterosexual intercourse. Therefore, the number of infected women will equal that of men. Consequently, more infants will be infected by their mothers and more infants will be orphaned as their parents die of AIDS. By the end of the 1990's, over one million adults, most of them in developing countries. Although the majority of HIV infections are currently occurring in Sub-Saharan Africa, the annual number of HIV infections in Asia is projected to exceed that in Africa during the 1990's. Also in industrialized countries, the proportion of heterosexual transmission is increasing, and AIDS is becoming one of the predominant causes of death in young men and women. In spite of promising scientific progress, vaccines and therapeutic drugs are not expected to have any major impact on the global development of the pandemic during the 1990's. The World Health Organization (WHO) is promoting behavioral changes, condom use, and control of other sexually transmitted diseases as the most important preventive measures. Insight into the dynamics of the HIV/AIDS pandemic and into the growing understanding of the main factors which are fuelling the continued and increasing HIV transmission is given. A short survey of the epidemiological background, the current trends, and the forecasts of the directions of the epidemic during the next decade are presented. Author

HIV infection (AIDS) burst upon the scene a decade ago. Because it is a sexually transmitted disease that infects blood and kills its victim, it is military relevant and will impact on all aspects of the military. The USAMRDC as Lead Agent for Infectious Disease Research in the DoD has developed a comprehensive approach to address military concerns: surveillance of infection rates (intelligence) around the world and in the military; behavioral research to develop more effective means of education to change behavior; and biological research to develop a quick and easy field test, and a vaccine or drug to prevent the disease from occurring despite exposure. Its success will influence the success of the Army in the future. Author

Between early 1986 and February 1991, over 700,000 United States Air Force (USAF) active duty personnel had been screened for antibodies to the Human Immunodeficiency Virus (HIV). All HIV-infected patients are evaluated at Wilford Hall USAF Medical Center, and staged using the Walter Reed scheme. Two total-force screenings were conducted prior to October 1990. The USAF case registry is maintained by the Epidemiological Research Division. Computer support for incidence calculations is provided by the Defense Manpower Data Center. During the first screening (February 1986-September 1988), 721 HIV-positive personnel were detected from a USAF population of approximately 607,000. The estimated seroprevalence was 1.2/1000. From the second screening 206 positive individuals were detected among approximately 571,000 personnel. As of January 1991, among the total 942 HIV-positives, only 29 were female. Three hundred and fifty-one (37.3 percent) remained on active duty in the US; 296 (31.5 percent) were on temporary disability retirement lists; 193 (20.5 percent) had separated or retired; and 101 (10.7 percent) had died. From June 1987 through June 1990, the estimated incidence of HIV infection in USAF personnel declined from 0.19 to 0.17/1000 person-years. The rate for males in June 1987 was estimated at 0.21/1000 person years. In all, the highest rate was among black males. In October 1985, the US Department of Defense (DOD) mandated that all applicants for military service be tested for evidence of antibodies to the human immunodeficiency virus (HIV). This testing continues, and if they test-positive, applicants are denied entry. Testing of those already in the US military services began soon afterward. Between early 1986 and February 1991, over 700,000 active-duty US Air Force (USAF) personnel were tested for the presence of HIV antibodies. In addition to two total-force (USAF, USAF Reserves, and Air National Guard) screenings prior to October 1990, USAF personnel have been tested in conjunction with: evaluation and treatment for other sexually transmitted diseases, routine and periodic physical examinations, enrollment in drug or alcohol rehabilitation programs, orders to permanent overseas assigments, and clinically-indicated medical reasons. The 1987-1990 HIV incidence estimates are discussed in a relatively young, mobile male population by age, ethnicity/race, sex, and occupational category at time of positive HIV antibody test. Author

The period of latency between infection by the human immunodeficiency virus type-1 (HIV-1) and the production of specific antibodies to viral antigens may be prolonged and, occasionally, may last for years. This condition of seronegative infection could represent a serious risk of viral transmission from subjects who are unaware of their status. However, whether these individuals are actually infectious, especially through body fluids, has not been clarified. We have performed a prospective study in 65 high risk individuals seronegative for HIV-1 antibodies for a prolonged period of time. Twelve of them (18 percent) were shown to be carriers of HIV-1 proviral sequences by the polymerase chain reaction (PCR). The virus was isolated from nitrogen-stimulated peripheral blood lymphocytes (PBMC) in five out of ten subjects tested since the first positive PCR. In two of them, virus could also be isolated from cell free plasma, subsequently they remained seronegative

during 10 months of follow-up. These data indicate that delayed seroconversions may be associated with productive infection, suggesting that mechanism(s) other than viral latency may be responsible for the absence of antibody responses to HIV-1 proteins. Furthermore our findings suggest that prolonged seronegative individuals can transmit HIV-infection through their body fluids. Author

Since Human Immunodeficiency Virus (HIV) was identified as the causative agent of Acquired Immunodeficiency Syndrome (AIDS) the pressing challenge that researchers are facing is the development of a vaccine against this disease. Although progress has been made in the study of the biology of HIV faster than for any other virus, the development of an effective vaccine has been slowed by the peculiar features of HIV. The difficulties standing before a rationale approach to vaccine design are: (1) the ability of the virus to rapidly change its genome sequency; (2) its spreading from cell to cell; (3) its ability to establish latent infection integrating its genome into that of the target cell without expressing any viral genes and, thus remaining hidden inside the infected cell; and (4) its insidious attack on the immune system upon which a vaccine depends in order to be effective. The design of a rationale approach to a vaccine is discussed. Author

Major advancements have been made in the laboratory assessment of the immune system over the past decade. There has been a proliferation of sophisticated techniques to measure the number and functional capacity of subsets of lymphocytes and other cellular elements of the immune system. Unfortunately, the space of this technology has made it difficult for many practicing physicians to develop and maintain an understanding of these new tests. Additionally, appropriate reference values for these tests in 'normal' populations are unclear and little has been done to assess the effects of factors such as age, race, and lifestyle on these measures of immunity. Laboratory assays are available to assess both the counts of the various cellular elements of immunity in the peripheral blood as well as the functional capacity of many of these cells. Tests of delayed cutaneous hypersensitivity are based on techniques used in allergy testing and tuberculosis control. After antigens such as Trichophyton or Candida are injected intradermally, the skin's reactivity correlates with the recall sensitivity of the T cells to each antigen used. Counts of total T lymphocytes (CD2 cells) and B lymphocytes (CD20 cells) are decreased in immune deficiency conditions and are elevated with lymphoproliferative diseases. The helper/inducer T lymphocytes (CD4 cells) are commonly decreased in progressive HIV infection and are increased in autoimmune disorders. The suppressor T cells (CD8) are increased in some viral infections and immunodeficiency states. The CD4/CD8 ratio is a commonly used measure of immune system capability. Tests of activated T lymphocytes (CD25 cells) assess the presence of stimulated T lymphocytes. Unstimulated T cells do not react to this test. This is a useful test in identifying the presence of lymphoproliferative disorders. Count of total lymphocytes is also made. Tests of the functional status of the cellular components of the immune system assess the response of the cells in the peripheral blood to stimulation with various mitogens such as phytohemagglutinin. These test measure the cells' capability to become activated by external stimuli. The natural killer cell assay measures the body's lytic response to foreign tissue cells both before and after stimulation with interlukin. This response is decreased with impaired natural immunity. Standard quantitative measurements of immune globulins (IgA, IgG, and IgM) are also useful in the assessment of immune functions. They measure the ability of specific B lymphocytes to secrete specific classes of antibody. A useful approach to the categorization of several of the quantitative and functional tests of immunity is shown. The tests provide a comprehensive assessment. As part of a comprehensive epidemiologic study of current and former Air Force personnel, an extensive assessment of the immune system was conducted by a single immunology reference laboratory using stringent quality control standards. All of the tests described above were used in this study. The demographic characteristics of these study subjects are displayed. All of the subjects were middle-aged males, most of whom did not currently smoke tobacco. Nearly 80 percent of them currently drink alcoholic beverages. Author

Human Immunodeficiency Virus (HIV) infection in U.S. Air Force personnel between 1985 and 1989 was examined through a mandatory serologic survey, and through annual examination of infected patients. CD4+ cell counts were determined by flow cytometry; Beta 2 microglobulin and neopterin were measured by immunoassay. During this period, 933 cases were found, of which 161 were documented seroconversions, giving an incidence rate of 15.6/100,000 person-years. For patients with greater than 400 CD4 cells/microliter, the rate of initial occurrence of opportunistic infection was 1 percent and 4 percent at 1 and 2 years, respectively. HIV infected persons with less than 400 CD4+ cell/microliter, in contrast, had rates of 21 percent at 1 year and 36 percent at 2 years. In a cross-sectional study, Beta 2 microglobulin concentration was shown to increase in both the serum and spinal fluid of patients infected with HIV as their blood CD4 numbers declined. Neopterin levels in serum and spinal fluid showed a similar trend, with significantly lower neopterin concentrations in the group that had greater than 1000 CD4+ T cells compared to the 0-600 CD4+ cell group. Longitudinal studies included correlation of HIV p24 antigen with CD4 counts over a one year period. The p24 antigen-positive group has a 21 percent decline in CD4+ T cells, while the antigen negative group has a 14 percent decline. Specific helper T-cell subsets were also examined over a 6 month period. A significant decline was seen in the CD4+/DC29+, CD4+/DC45R+, and overall CD4+ subsets which were not seen in AZT treated patients. A significant increase in the CD4+/CD29+ memory T-cell subset, which is responsible for response to recall antigens and is capable of Upsilon interferon secretion, was noted in the AZT-treated group. A nonparametric estimator of the Acquired Immunodeficiency Syndrome (AIDS) survival time (after developing AIDS) is computed for the AIDS data set from the US Air Force (USAF). Survival times are unobservable. They are censored by the screening mechanism. The Armstrong Laboratory's Epidemiologic Research Division maintains data on over 940 active duty US Air Force (USAF) individuals who tested positive for Human Immunodeficiency Virus (HIV) antibodies. Many have been clinically evaluated six times since 1986. The HIV-positive individual is classified in seven stages of the disease complex as time

progresses. Exact times of transition from one stage to the next are unknown. It is known that transition occurred between two consecutive evaluations. The aim of this study is to analyze distributions of the times that individuals spend in each stage of the HIV disease complex. We discuss methods used to obtain nonparametric estimators of the distributions of times that individuals spend in stage 6. Finally, we hope to model the median time spent in each stage of the disease. This, along with incidence and separation data, will allow us to predict the impact of HIV disease on USAF individual and medical care systems. Author

There has been controversy about whether cognitive changes occur in early human immunodeficiency virus (HIV) disease. In those studies reporting cognitive changes, findings are typically subclinical, and their relationship to daily and/or occupational functioning has not been addressed. The potential effects of changes may vary as a function of occupational demands. This is germane to military performance, where occupational demands cover a wide spectrum of complexity. In particular, such effects are important to consider in the many cognitively-demanding specialties associated aviation. Ways in which possible HIV-related military performance decrements in aviators may be measured empirically are explored. First, studies from Walter Reed Army Medical Center (WRAMC), which have shown cognitive changes in early HIV disease, are described. This is followed by a summary of presentations and discussions at a November, 1990 conference, entitled, HIV and Military Performance: Assessment Methodologies, held at WRAMC. The third section describes a program of research, which is developing measures to detect cognitive difficulties in civilian aviators. The application of measures from this research to research on HIV is discussed. Finally, a research program being developed to examine the possible impact of HIV-related cognitive changes on military aviator performance is presented. Author

The Military Medical Consortium for Applied Retroviral Research's (MMCARR) Behavioral Medicine Human Immunodeficiency Virus (HIV) Research component is conducting a tri-service, comprehensive, and longitudinal research study in military HIV-infected personnel at all stages of infection. Identification of neuropsychiatric and psychosocial outcomes and their determinants will help the military minimize the impact of the HIV epidemic on military readiness and function. Neuropsychiatric and psychosocial findings are among the most common complications seen in early HIV Disease and among the most likely to have an adverse impact on military readiness and function. The study has demonstrated that the average HIV-infected service-person experiences at least transient military occupational difficulty following notification of HIV status. More than 15 percent at any given time have levels of clinical or subclinical anxiety or depression that are referrable for mental health intervention. Ten percent of study subjects have a current major mood disorder and 5 percent have a psychoactive substance use disorder. Finally, 17 percent of study subjects have experienced serious suicidal ideation or behaviors at least once since notificaiton of seropositivity. Fortunately, however, data also indicate at least partial effectiveness of current primary, secondary, and tertiary preventive efforts. Only about 1 percent of Air Force HIV-infected persons are discharged for psychiatric reasons prior to eventual medical discharge. Further, a large majority of active-duty patients demonstrate solid military occupational and social performance. Though military HIV neurobehavioral research is still in progress, preliminary data identify social support and pre-HIV psychiatric predisposition as important factors associated with current neuropsychiatric status. Communicable diseases, complicated by malnutrition and other adverse socioeconomic factors, continue in the present decade to contribute greatly to the unacceptably high levels of morbidity, mortality, and disability, particularly in the under-five age group, in all developing countries. It is estimated that five million deaths occur per year from diseases which can be prevented by vaccines available today, and that another five million people are being crippled, blinded, or mentally retarded as a result of the same diseases. Some of the most important communicable diseases, with their mortality rate, are reported. Some of the topics discussed include sexually transmitted diseases, disease control, chemotherapy, and environment management. Author

Because of increasing incidence of mumps in a cohort of under immunized young adults and the concern about the impact of this disease on the USAF recruit population, two studies were undertaken. These studies took a retrospective look at the following: mumps in the active duty population; a cost analysis of immunizing all or only susceptible individuals; the actual antibody response in a group of two hundred and seventy-six recruits in basic training; the demographic patterns of susceptibility; and the types of previous immunication documentation. The conclusions were that the numbers of new mumps cases per year did not justify immunizing all recruits or screening for mumps antibodies. Author

The schedule of vaccination which is recommended worldwide for diphtheria, tetanus, and other diseases provides good immunity during childhood. However, little attention has been paid to keep an effective immunity in adults. We have collected sera from 334 recruits of the Italian Army and tested them for the presence of protective immunity against diphtheria and tetanus. In vivo neutralization assays were performed on rabbits and mice and the values below 1/100 IU/ml were considered negative. Of the recruits, 22.9 percent were negative for diphtheria, while only 5.3 percent of them did not have protective immunity against tetanus. This finding shows that a large proportion of the Italian young adults are susceptible to diphtheria, and this could be dangerous if they travel to sites where this disease is still endemic, or if they come into contact with people coming from such areas. A booster vaccination of young adults against diphtheria should enter in the common practice in order to avoid this risk. In order to reduce the side effects which are often associated with diphtheria vaccination in adults, we have developed a vaccine which contains a highly purified nontoxic mutant of diphtheria toxin. This vaccine

is combined with tetanus toxoid and can be routinely used as a booster in adults. Author

DRAMATIC REDUCTION OF MENINGOCOCCAL MENINGITIS AMONG MILITARY RECRUITS IN ITALY AFTER INTRODUCTION OF SPECIFIC VACCINATION

R. BISELLI, A. FATTOROSSI, P. M. MATRICARDI, R. NISINI, T. STROFFOLINI, and R. DAMELIO (Istituto Superiore di Sanita, Rome, Italy) *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 5 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

Meningococcal meningitis still represents a serious infectious disease with a mortality rate that can be as high as 10 percent even in developed countries. Military recruits are generally a high risk group for meningococcal disease, with a reported incidence of 4 to 10 times greater than that of the general population. In Italy the results of the National Meningitis Surveillance Program showed a high attack rate of the disease among recruits in 1985 as well as in 1986, with 92 and 95 percent of the cases, respectively, caused by serogroup C and thus preventable. These findings constituted the motivating factors leading to the authorities' decision to make vaccination against meningococcal disease mandatory for recruits starting from January 1987. After almost 5 years from the introduction of meningococcal vaccination, we present a summary of the epidemiological and immunological effects of the vaccination. From the epidemiological point of view we have observed a dramatic reduction of the prevalence of the disease. In 1987, that is the year in which we had 150,000 unvaccinated and 150,000 vaccinated recruits, the protective efficacy was 91.2 percent. From the immunological point of view, vaccination is highly effective, as seroconversion against polysaccharide (PS) A and C is 84 and 91 percent, respectively. The spectrotypic analysis of the sera before and after vaccination shows that the type of response is mainly oligoclonal, like the majority of the responses to PS's, and the antibodies induced by sole PS are not qualitatively different from the antibodies induced by natural immunization. In addition, the efficacy is not modified by environmental factors like hypoxia, as demonstrated during permanence at 16,174 feet for 20 days. In conclusion, the anti-meningococcal PSA and PSC vaccine can be looked at as a very safe and effective method in controlling the spread of the disease in military recruits since: (1) its efficacy is very high, considering approximately 90 percent of the subjects develop a protective response; (2) it is safe; and (3) it has proven to provide satisfactory immunological response even under unfavorable conditions, like hypobaric hypoxia. IMMUNIZATION OF PERSONNEL TRAVELING TO A DESTINATION IN TROPICAL COUNTRIES: FRENCH POSITION [IMMUNISATION DU PERSONNEL NAVIGANT A DESTINATION DES PAYS TROPICAUX: POSITION FRANCAISE]

F. DIDELOT, C. P. GIUDICELLI, J. P. GOURBAT, J. P. BURLATON, G. NEDELEC, and A. SEIGNEURIC *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 3 p (SEE N93-11283 02-52) Apr. 1992 In FRENCH

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

The possibility of infectious risks incurred during sojourns in tropical zones justifies preliminary prevention. Aside from obligatory measures, it is important to discern recommended and other desirable actions. The obligatory measures essentially concern antimalarial vaccination for those personnel whose travel brings them into the intertropical zones of Africa and America. The partial and limited efficacity of the anticholera vaccination has practically justified its abandonment. The recommended measures include vaccinations against tetanus, diphtheria, poliomyelitis, (BCG) and typhoid. Obligatory in France for all children, except for the latter, these vaccinations must be replaced by boosters for all adults. Well tolerated, the new vaccine against typhoid (polyosidic, purified Vi antigen) merits being systematically employed. Other immunizations are desirable: vaccinations against meningococcic meningitis (serogroups A and C) in the young adult and against viral hepatitis B and injection of gammaglobulins for the prevention of hepatitis A virus. Finally, the high tolerance for anti-rabies vaccine leads to counseling the generalization of its use, due to the possible risk of a supply default at an opportune moment. Contradictions are restated and a vaccinal calendar is proposed. Aside from oral forms of vaccines against cholera and against typhoid, future perspectives concern vaccines against viral hepatitis A and against Japanese encephalitis. These are directed against the major risks, those such as malaria and AIDS unfortunately appear, even today, to be aleatory. Author

The clinical and immunological responses to typhoid vaccination with parenteral and oral vaccines in two groups of 30 adult male subjects were studied. Specific anti-Salmonella typhi cell-mediated immunity and total or specific anti-lipopolysaccharide fecal immunoglobulin (Ig) A titers in vaccinated subjects were monitored. Cellular antibacterial activity was significantly increased only in orally vaccinated subjects. Serum arming activity and inhibition experiments suggested an IgA-dependent cellular cytotoxicity in those orally vaccinated. In these subjects, a total and anti-lipopolysaccharide fecal IgA increase was observed lasting up to 8 months after completion of vaccination schedule. In parenteral vaccinated subjects, an early onset transitory increase of IgM rheumatoid factor was observed. Oral vaccine was well tolerated and free of side effects, whereas 65 percent of parenterally vaccinated subjects reported side effects such as fever, headache, malaise, and local tenderness in the injection site. STUDIES OF SAFETY, INFECTIVITY, AND IMMUNOGENICITY OF A NEW TEMPERATURE SENSITIVE (TS) 51-1 STRAIN OF S. TYPHI AS A NEW LIVE ORAL TYPHOID FEVER VACCINE CANDIDATE

J. A. BELLANTI, B. J. ZELIGS, S. VETRO, Y.-H. PUNG, S. LUCCIOLI, M. J. MALAVASIC, A. M. HOOKE, T. R. UBERTINI, R. VANNI, and L. This report describes the results of a phase 1 study evaluating the safety, infectivity, and immunogenicity of a new live oral S. typhi ts 51-1 typhoid fever vaccine in the human. Three normal males subjects ranging in age from 20 to 40 years received 3 oral doses of S. typhi ts 51-1, each dose containing 10(exp 9) organisms. Prior to and following immunization each subject was carefully monitored by clinical and laboratory parameters over a two week period during which serial specimens of blood and stool were analyzed for the presence of the organism. Blood specimens were also obtained for the determination of serum antibody and cell-mediated immune responses and stool filtrates were analyzed for the development of coproantibody. The results of these studies indicate that: (1) the vaccine is well tolerated with no clinical or laboratory evidence of adverse reactions; (2) ts 51-1 was detected in only one stool specimen from one volunteer; the organism recovered displayed characteristics of the ts 51-1 vaccine strain; (3) although no significant humoral or cell-mediated lymphocytotoxic immune responses were detected in the blood, coproantibody was detected in stool specimens from all of the 3 immunized subjects and IgA-armed ADCC activity was detected in 2 of 3 subjects. These studies indicate that S. typhi ts 51-1 may be a suitable strain for the development of an improved oral typhoid fever vaccine. Studies are in progress to determine optimal methods of vaccine delivery preparatory to larger phase 2 studies of efficacy. Author

RECENT LESSONS ON THE SAFETY AND EFFECTIVENESS OF MALARIA CHEMOPROPHYLAXIS IN A NON-IMMUNE POPULATION

R. STEFFEN *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 4 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

To assess adverse events (AE) and the effectiveness of malaria chemoprophylaxis in short term travelers to East Africa, two similar follow-up studies were conducted, the second of which is on-going. Pooled data of both studies are presented, in which all passengers returning from Kenya by British, German, or Swiss charter flights were distributed a questionnaire aboard and a second one three months later. Any report of documented malaria or of a hospitalization for adverse events was investigated with the physician. So far, 98,650 travelers have completed at least one questionnaire. AE were reported by 22.3 percent of 30,871 having used mefloquine (MQ), by 19.9 percent of 5,342 having used chloroquine (CQ) 300 mg base/week, by 22.2 percent of 7,930 having used Q 600 mg base/week, by 29.4 percent of 1,114 having used amodiaquine (AQ), by 1.63 percent of 24,532 having used sulfadoxine/pyrimethamine (SP), and by 26.1 percent of 6,851 having used CQ plus proguanil (PG). Dizziness was more frequent with MQ than with other agents. Twenty hospitalizations were attributed to AE: seven occurred after prophylaxis with CQ (including 2 cases of psychosis), four were attributed to SP (2 fatal), and five to AC (2 fatal). Just two were attributed to MQ: one each for psychosis and one for seizures in a known epileptic, one additional case with seizures was not hospitalized. Prophylactic effectiveness was 94 percent (95 percent C.I. 85-96) for MQ, 84 percent (77-90) for SP, 74 percent (48-88) for CQ+PG, and 30-54 percent for CQ in various dosages. In conclusion, mefloquine appears to be highly efficacious for malaria prophylaxis in areas with widely distributed chloroquine resistant P. falciparum. Tolerance seems to be comparable to the one of chloroquine; thus, the contra-indication of the use of mefloquine in pilots will have to be reconsidered. Author

The immune effector mechanisms responsible for the solid protection against malaria, as demonstrated by immunization with radiation attenuated sporozoites, are poorly understood. An effective malaria vaccine must induce a well orchestrated combination of humoral and cellular immune responses directed against critical parasite antigens/epitopes expressed during different stages of the parasites complicated life-cycle. Currently, licensed human vaccine adjuvants, such as alum, may improve antibody production but are poor stimulators of cellular effector mechanisms, while potent cellular stimulants such as Freund's adjuvant are too reactogenic for human use. Over the last five years, we have systematically evaluated several methods of antigen presentation to include chemical conjugation to bacterial carrier proteins, emulsification in 'Freund's-like' preparations, and incorporation into liposomes. This work has resulted in the production of safe, potent vaccine delivery systems capable of targeting multiple antigenic determinants to the host's immune system. Further advances in malaria vaccine development now depends on the identification of appropriate parasite epitopes for inclusion in a multicomponent-multistage vaccine. Author

CYTOKINES AS VACCINE ADJUVANTS: INTERLEUKIN 1 AND ITS SYNTHETIC PEPTIDE 163-171

ALDO TAGLIABUE *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 5 p (SEE N93-11283 02-52) Apr. 1992

The possibility of preventing infectious diseases by employing efficacious vaccine is rapidly growing as the consequence of the new technologies in recombinant DNA and protein chemistry. However, the increasing number of synthetic and recombinant antigens further stresses the importance of the role of appropriate adjuvants to ensure the maximal vaccine activity and the protection of all vaccines. Several approaches can be applied to develop safe and effective agents capable of enhancing specific immune responses which can then protect the host from the pathogen. Among others, the direct use as adjuvant of those cytokines which are induced in animals by the classical Freund adjuvants has recently become a matter of investigation. In particular, interleukin 1 (IL-1) has been shown to possess adjuvant activity for a variety of infectious and tumor antigens. However, the numerous side effects associated to the proinflammatory action of IL-1 represent a serious disadvantage for its use as a vaccine adjuvant. Therefore, it was of great interest that the observation of a nonapeptide contained in the IL-1beta sequence (residues 163-171 corresponding to the sequence VQGEESNDK) is devoid of all the proinflammatory activities but maintains the immunostimulating activity of the whole IL-1beta. Thus, 163-171 peptide was successfully employed in animals to potentiate the specific immune response against T helper-dependent cellular antigens, T helper-independent polysaccharidic antigens and recombinant, as well as synthetic antigenic preparations derived from human pathogens. Furthermore, IL-1 and 163-171 peptide were successfully used in tumor vaccines in experimental systems. Therefore, it can be concluded that 163-171 peptide is potentially a good candidate as vaccine adjuvant for human use. Author

FUTURE APPROACHES TO VACCINE DEVELOPMENT SINGLE-DOSE VACCINES USING CONTROLLED-RELEASE DELIVERY SYSTEMS

M. T. AGUADO *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 4 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

The development of new vaccines, both more efficacious and easier to deliver, has become an area of research that can certainly benefit from recent technical developments. In particular, the conversion of multiple-dose vaccines into single-dose vaccines may represent an important advance which should lead to improved vaccination coverage, as well as to a reduction in vaccination costs. Taking these considerations into account, one of the main goals of our program has become the development of a strategy to convert multiple dose vaccines to single-dose vaccines with the same or increased effectiveness. The initial priority of this project was to develop a single-dose tetanus vaccine, as one of the most urgent needs of the Expanded Program on Immunization to control neonatal tetanus. The use of controlled-release systems, already applied to deliver a whole array of drugs and hormones both in cattle and man, appears to be one way of accomplishing our goal. Among these systems, polymeric particles have been widely used for injectables. They can be classified into two main groups: the reservoir type, with material in solution in the cavity formed by a polymeric membrane; and the monolithic type, with materials evenly dispersed throughout the polymeric matrix. Indeed, the first type is usually known as microcapsules and the second as microspheres. Microspheres seems to be preferred to microcapsules because of the better control of drug or vaccine liberation. At present, the pre-clinical results obtained seem to point in the direction of the successful development of single-dose controlled-release vaccines. Author

EPIDEMIOLOGIC VIEW OF ALLERGIC DISEASES IN NORTH AMERICA: IMPLICATIONS FOR AEROSPACE MEDICINE

J. A. BELLANTI *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 3 p (SEE N93-11283 02-52) Apr. 1992

The allergic disorders comprise a heterogeneous group of diseases which involve the respiratory tract (e.g., allergic rhinitis and asthma), the skin (e.g., atopic eczema), and the gastrointestinal tract (e.g., allergic gastroenteritis, food allergy) and which afflict 50 million Americans. The respiratory allergic diseases affect major segments of the population (15 to 17 percent) who may be recruited as aircraft personnel; therefore, these diseases pose particular risk to flying safety or personnel either directly, or indirectly as a consequence of their disease or of the adverse effects of medications now used in the treatment of these disorders. Moreover, recent evidence is now accumulating to suggest that other environmental factors encountered in aerospace operations, e.g., gravity, oxygen, and stress, may also contribute to the immunologic responses involved in and responsible for clinical manifestations of these allergic disorders. A thorough knowledge of these allergic diseases and reactions associated with therapy are, therefore, essential for proper screening of personnel prior to entry into the aerospace field. Moreover, principles of allergic therapy should be applied to existing trained personnel and combined with a knowledge of careful use of medications which are least likely to be associated with performance decrement. The availability of new medications which have minimal adverse effects, e.g., non-sedating antihistaminic drugs, are addressing some of the problems associated with these issues. Author

THE SCREENING OF INHALANT ALLERGIC DISEASES IN THE SELECTION OF CANDIDATES FOR AIRCRAFT PILOTING

P. M. MATRICARDI, R. NISINI, R. BISELLI, L. URBANI, C. DEANGELIS, G. PETRELLI, and R. DAMELIO *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 5 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

The validity of Phadiatop CAP as a tool in the mass screening for inhalant allergies was investigated. Two-hundred and seventy of 1815 Italian recruits were classified as allergics to inhalant allergens on the basis of history, physical examination, SPT for inhalants, and/or RAST for the seven most common aeroallergens in Italy. Phadiatop was positive in six-hundred and twenty-three (34.3 percent) subjects: in 265/270 allergics and in 357 subjects which had never experienced allergic symptoms; the vast majority of these subjects were also positive to STP and/or RAST. The level of Phadiatop reactivity was lower in this group with respect to the allergic one. In a subgroup of 98 subjects, bronchial hyperresponsiveness was also examined. A very high percentage (85 percent) of the subjects with bronchial hyperresponsiveness were also positive to Phadiatop, suggesting that atopy is one of the major etiologic factors of bronchial hyperreactivity in our population sample. We conclude that Phadiatop CAP is extremely useful in the screening of inhalant allergies in candidates to aircraft piloting. Author

PHADIATOP: A SCREENING TEST FOR INHALANT ALLERGY

A. M. J. WEVER *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 3 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

The Phadiatop test, a new in vitro test for inhalant allergy, was evaluated in relation to a panel of seven RAST tests with the common inhalant allergens in the Netherlands, and in comparison with the PRIST for total immunoglobulin E (IgE) determinations, in two populations: one in which the prevalence of inhalant allergy was expected to be high and one in which it was expected to be low. The Phadiatop was classified positive or negative according to percentage binding, total IgE was considered elevated at values greater than or equal to 200, greater than or equal to 150, and greater than or equal to 100 kU/l at ages 12-14, 15-16, and 17 years and over respectively. The RAST panel as reference was considered positive when at least on RAST result was class 2 or more. From the predictive values (which depend on the prevalence of the disease in the population) and the accuracies of the Phadiatop and the PRIST for the RAST, it can be concluded that the Phadiatop is a highly efficient test, much more so that the PRIST, in correctly classifying atopic and non-atopic subjects as judged by the reference RAST panel. IN VIVO AND IN VITRO DIAGNOSIS OF ALLERGIC RESPIRATORY DISEASE DURING SCREENING PROCEDURES IN THE ITALIAN NAVY: COMPARATIVE EVALUATION OF A RECENT QUANTITATIVE AUTOMATIZED ENZYME IMMUNOASSAY METHOD TO DOSE SPECIFIC IGE

G. ANZALONE, M. DELTRECCO, A. VIZZACCARO, and A. CORSICO *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 7 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A02/MF A03

The observation of a large number of young allergic patients gave us the possibility to acquire crucial information on the epidemiology, the aetiology, and the pathogenesis of respiratory allergies and particularly that of bronchial asthma. The diagnostic protocol used accomplished in a satisfactory way the proposed tasks to screen allergic conscripts and to clinically study already in service patients. Our evaluation of the recently introduced immunoassay ABBOTT-MATRIX confirmed its characteristics of specificity and reproducibility. It also demonstrated to be an easy to use 'in vitro' system with very poor requirements of intervention by the operator. We emphasize the need to routinarly introduce 'in vitro' research of allergies for the preliminary screening of the candidates to the Military Academies, the schools for P. Officers, and to special categories with an expensive training and high risk, like pilots or divers. Author

ASTHMA IN AIRCREW: ASSESSMENT, TREATMENT AND DISPOSITION

GARY W. GRAY *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 4 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

Asthma represents a spectrum of increased airway reactivity from mildly increased responsiveness through to severe life-threatening bronchospasm. Rational recommendations for treatment and aeromedical disposition require a careful assessment of bronchial reactivity through correlation of the clinical findings with results of pulmonary function testing including an objective measure of airway reactivity. Airway challenge testing with methacholine allows a safe, objective assessment of airway reactivity. In the Canadian Forces, aircrew candidates with a history of wheezing, recurrent cough or bronchitis in childhood, or abnormal screening PFT's are further screened with an airway challenge test. Applicants with a PC20 less than 4 mg/ml are disqualified from pilot selection, and less than 2 mg/ml from other aircrew. Trained aircrew who develop wheezing are assessed with full pulmonary function testing including a methacholine challenge test. Those with objectively confirmed mild bronchial hyper-reactivity requiring no treatment or controlled by inhaled anti-inflammatory agents (corticosteroids, sodium cromoglycate, nedocromial sodium) are returned to flying in other than fast jets where even minor small airway instability may worsen ventilation-perfusion mismatch caused by +Gz. ALLERGY SCREENING AND FOLLOW-UP IN STUDENT PILOTS OF THE BELGIAN AIR FORCE (BAF)

N. MORTIER, P. VANDENBOSCH, and C. VANCUTSEM *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 3 p (SEE N93-11283 02-52) Apr. 1992

(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

The different methods used in the Medical Center of Aerospace Medicine, Brussels (Med C Aerospace) to detect allergy in pilot applicants, are discussed. During the period 1987 through 1989,

the Total immunoglobuline E (IgE) levels were also determined at the start of pilot training. The aim was to assess if Total IgE could be used as an additional selection criterion. We conclude that it is not useful to determine the total IgE in the selection of pilot candidates. The existing investigations and examination methods are sufficient to detect allergy. Author

ALLERGIC AND NONALLERGIC RHINITIS IN GREEK PILOTS
C. GRIGOREAS, D. PAPPAS, A. AGELIDIS, and E. CHIMONAS *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 3 p (SEE N93-11283 02-52) Apr. 1992
(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

In order to study the Allergic Rhinitis (AR) and Nonallergic Rhinitis (NAR) in Greek pilots, we examined 144 Greek male pilots, aged from 23 to 50 years, with symptoms of chronic rhinitis. The diagnosis was based on: (1) detailed history; (2) physical examination; (3) Skin Prick Tests (SPT) on common aeroallergens (positive SPT greater than 3 mm wheal); and (4) nasal secretions for assessment of eosinophilia (positive eosinophilia 20 percent eosinophils in nasal smears). Also, we measured serum total immunoglobuline E (IgE) (IV/ml) by the Paper-Radioimmunosorbent Test (PRIST) method and expressed as geometric mean value. We excluded patients suffering from chronic rhinitis (infections, mechanical-anatomic, drug-induced, sinusitis, and metabolic states) and bronchial asthma. Eighty-six patients (59.7 percent) had Seasonal Allergic Rhinitis (SAR), 30 patients (20.8 percent) had Perennial Allergic Rhinitis (PAR), 22 patients (15.3 percent) had Vasomotor Rhinitis (VR), and 6 patients (4.2 percent) had Nonallergic Rhinitis with Eosinophilia (NARE). One patient with PAR and 2 patients with NARE possessed nasal polyps. The frequency of major positive SPT in the SAR group was: (1) grasses (80.2 percent), (2) olive (69.7 percent), (3) parietaria (50 percent); and in the PAR group was: (1) House dust (100 percent), (2) mite D. Farinae (93.3 percent), (3) mite D. Pteronyssinus (90 percent). The levels of IgE among the four groups were 174.6 IV/ml in the VR group and 39.2 IV/ml in the NARE group. It is concluded, that in Greek pilots: (1) AR (SAR and PAR) was more frequent than NAR (VR and NARE); (2) the major aeroallergens responsible were different in patients with AR, since pollens predominated in the SAR group and house dust-mites in the PAR group; (3) patients with NARE had a high prevalence of nasal polyps; and (4) IgE levels were higher in patients with AR (SAR and PAR) than in patients with NAR (VR and NARE). CORRELATION OF SERUM ALPHA SUB 1 ANTITRYPSIN WITH CIGARETTE SMOKING AND PULMONARY FUNCTION STATUS IN GREEK PILOTS, FOR A TEN YEAR PERIOD
J. PALERMOS, K. KYRIAKOS, S. MICHALOPOULOU, CH. DASKALOPOULOS, and A. BITSAKTSIS *In* AGARD, Allergic, Immunological and Infectious Disease Problems in Aerospace Medicine 3 p (SEE N93-11283 02-52) Apr. 1992
(AGARD-CP-518) Copyright Avail: CASI HC A01/MF A03

Quantitative and mainly qualitative aberration of the alpha sub 1 Antitrypsin (a sub 1 AT) a major constituent of the human antielastase screen, is strictly associated with the development of lung emphysema. Certain factors like cigarette smoking and environmental pollution may contribute to that. In this study, we have correlated cigarette smoking with the serum a sub 1 AT concentration as well with the trend of predicted values of Forced Vital Capacity (FVC) and 1st Second Forced Expiratory Volume (FEV sub 1) over a ten year period. The study population consisted of 113 randomly selected male pilots, of the Greek Airforce, being in flight duties grouped into nonsmokers ($n = 49$, age $x = 36.3$) and effective smokers ($n = 64$, age $x = 38.4$) smoking for more than ten years. Serum a sub 1 AT level was 176 plus or minus 36 md/gl (mean plus or minus SD) and 199 plus or minus 32 mg/dl for nonsmokers and smokers, respectively (p less than 0.001). Serum a sub 1 AT level for Greek male population was 190 plus or minus 35 mg/dl and the frequency of individuals with intermediate serum a sub 1 AT level was 2.7 percent. Recent and past (ten years ago recorded) FVC and FEV sub 1 predicted values were measured. This data suggest that: (1) cigarette smoking affects serum a sub 1 AT level; (2) intermediate serum a sub 1 AT level cannot be employed as a predictive criterion for flight personnel's pulmonary status; (3) ten years of cigarette smoking worsens the pulmonary function status significantly; and (4) extra physical exercise improves it. OPERATIONAL USE OF CONTACT LENSES BY MILITARY AIRCREW [L'UTILISATION OPERATIONNELLE DES LENTILLES DE CONTACT]
E. ALNAES, ed. Oct. 1992 36 p
(AGARD-AG-334; ISBN-92-835-0690-1; AD-A258675) Copyright Avail: CASI HC A03/MF A01

The text discusses the operational requirements of military personnel relative to the use of contact lenses (CL) and particular emphasis is given to the experience of those NATO air forces that currently have aircrew flying with contact lenses. Topics such as lens optical performance, user compliance, and a definition of adequate eye-care supervision are highlighted. The text seeks to identify the critical factors to be taken into account when the decision is made to permit the use of contact lenses by military aircrew, and weights medical considerations and military field conditions, in this regard. Finally, specific military aeromedical conditions in modern aircraft are discussed, with emphasis on the advantages and disadvantages of CL visual correction. Based on extensive deliberations in the group, WG 16 offers a detailed list of recommendations for the use of CL by military aircrews. These recommendations will also be useful for military medical authorities supervising visual correction guidelines for non-flying personnel. Author

The Abbreviated Injury Score (AIS) and Injury Severity Score were calculated for all passengers and crew of the M1 Kegworth aircraft crash. Regional scores were significantly higher in nonsurvivors than survivors of the impact. Mortality and ISSs were found to correlate with the structural damage sustained by the aircraft. The use of injury scoring has highlighted variations in the severity of injuries sustained by occupants involved in an impact aircrash. This information has demonstrated that other factors in addition to the force of the impact were involved in the causation of injury, such as structural integrity, attempts by occupants to protect adjoining passengers, being struck by loose objects and rear facing seats. Author

IS AXIAL LOADING A PRIMARY MECHANISM OF INJURY TO THE LOWER LIMB IN AN IMPACT AIRCRAFT ACCIDENT?
J. M. ROWLES, P. BROWNSON, W. A. WALLACE, and D. J. ANTON (Royal Aerospace Establishment, Farnborough (England).) *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 8 p (SEE N93-19653 06-03) Sep. 1992
(AGARD-CP-532) Copyright Avail: CASI HC A02/MF A04

Following the crash of a Boeing 737-400 aircraft on the M1 motorway near Kegworth, England, on 8 January 1989, it became apparent that a large number of pelvic and lower limb injuries had been sustained by the survivors. Had there been a fire this would have severely hindered the ability of the occupants to escape. The mechanism of pelvic and lower limb injuries in impact accidents has been related to failing of the limbs and axial loading of the femur. The validity of axial loading of the femur as a primary mechanism of femoral fracture in an impact aircraft accident is questioned. Two methods of study have been used to investigate the impact biomechanics of the pelvis and lower limb: clinical review and impact testing using anthropomorphic dummies. Our study suggests that in the presence of intact occupant protection systems, bending of the femur over the front spar of passenger seats is the primary mechanism of causation of femoral fractures.

Occupant protection systems designed for civil aircraft should be modified to accommodate loading of the femur over the front of the seat. Author

A number of 20 military pilots drank certain amounts of alcohol until the blood alcohol concentrations reached a level of about 0.8 o/oo. After that they had to fly an IFR mission using the flight simulator for 2 1/2 hours. They were told to perform the complete program of navigation and flight operations and also communications with, for example, air traffic control (ATC). During the simulated flight programmed technical failures occurred concerning the instruments and the engine. The reactions of pilots and the cause were registered. The results were obtained by summarizing false reactions. Significant differences in the number of wrong reactions due to alcohol consumption were registered. Author

FIRES ON BOARD AIRCRAFT: TOXICOLOGICAL RISK IN FLIGHT [INCENDIES A BORD DES AERONEFS: RISQUE TOXICOLOGIQUE EN VOL]
M. KERGUELEN, M. MIGNET, and J. M. JOUANY *In* AGARD, Aircraft Accidents: Trends in Aerospace Medical Investigation Techniques 12 p (SEE N93-19653 06-03) Sep. 1992 In FRENCH
(AGARD-CP-532) Copyright Avail: CASI HC A03/MF A04

At the time of fires on board aircraft, intoxication by the products of the thermolysis of the materials used in the installation of the cabin represents a major risk. To evaluate the toxic risk of fires on board aircraft in flight, it is necessary to take into account not only the ventilation but also the pressure of the cabin, which can vary between 1000 and 750, even 700 hPa. An original model fire was developed, making it possible to study, under ventilation conditions representative of an aircraft, the influence of the pressure on the thermolysis of various materials. Thermolysis was considered on physiochemical and toxicological levels, the mouse being chosen as the experimental animal. The study showed that the toxic risk varies considerably according to the material considered. In addition, under these experimental conditions, the barometric pressure drop from 1000 to 700 hPa hardly modified the physicochemical characteristics of the thermolysis of the majority of studied materials. On the other hand this pressure drop generally generated a very significant increase in toxicity of the generated gas mixture, in which carbon monoxide and/or hydrocyanic acid have a dominant share. After accidents with fume in the cockpit a characteristic profile of pyrolysis products is gaschromatographically often detectable in the blood. This profile we have to distinguish from an inhalation of fuel or from a fasting blood. The sensitivity was improved. If carbonyl compounds are supposed in the biological materials, we identify them by the reaction with semicarbazide in the head space bottles of the gaschromatograph. From about 5 percent CO-Hb, we determine photometrically the cyanide level. After a fatal crash over the sea bromide-concentrations were found in the examination materials, which exceeded clearly the physiological area. All previous results with essential longer immersion-times in sea-water told against a contingent uptake of bromide from the sea. Experiments with animal and human lungs demonstrated, that we have to calculate with such an enrichment in biological materials yet. With this knowledge, a second pilot in an analogous case could be cleared from the suspicion of having abused bromine containing sedatives, too. In estimating from a corpse, we ascertained gaschromatographically distinct higher values than with the enzymatic method. Further examinations showed that, caused by bacterial putrefaction, an alcohol formation occurred during the sample preparation. Any alcohol concentrations in the elder literature have to be regarded under a new aspect after that. In some investigations of dead pilots we identified hypnotics. In one case it succeeded to determine the time of intake with the more unspecific thin-layer chromatography instead of mass spectrometry. According to that, the extraction procedures became modified. The different used extraction methods for the single drug categories will be compared. Author

The west German armed forces Aerospace Pathology and Toxicology was founded in April 1964 as a division of the German Airforce Institute of Aerospace Medicine. Prof. S. Krefft was assigned the development of this division in a time of increasing accident rates due to the so-called 'F-104 G Starfighter crisis'. Krefft developed the concept of a mobile, airborne investigation and autopsy team with centralized laboratories for identification, histopathology and toxicology at Furstenfeldbruck AFB, near Munich. Though the doctors of the autopsy team normally are addressed as pathologists, they are in fact forensic pathologists, thereby meeting the requirements of German law. Trends in accidents and incidents are evaluated and discussed with respect to future developments. New methods and techniques are presented such as DNA-based identification. Author

The Division of Aerospace Pathology and Toxicology ('Flugunfallmedizin') at the German Air Force Aerospace Medical Institute was founded in 1964 by Col. Prof. Krefft and is since then located at Furstenfeldbruck AFB near Munich. The Division is engaged in the medical and medico-legal part of all fatal accident - most non fatal accident - and incident investigations concerning German military aircraft (Airforce, Navy and Army). The Division performs also some civilian medical accident investigations for the Federal Aviation Administration ('FUS, Flugunfall Untersuchungsstelle beim Luftfahrt Bundesamt'). The autopsy files of the period 1 January 1965 up to 31 December 1990 were reviewed. In 231 civilian and military crashes a total of 455 autopsies was performed, resulting in 385 valid autopsy reports of killed pilots including a histopathological examination. Histopathological findings were coded and stored in a data base of an IBM compatible computer. In those cases with positive histopathological findings in the files the tissue was reexamined. 36 cases showed severe histopathological alterations. 21 of these might be considered to have reduced physical and/or mental performance and thus have affected the capability of flight safety. A selection of ten cases is used to discuss problems of accident causality in case of positive histopathological findings. The value and validity of findings especially in those cases of a high degree of tissue destruction is demonstrated. In aircraft accident investigations autopsy and histopathological examination must - on the basis of nearly 5 percent positive histopathological findings - be regarded as mandatory. Author

Military flying is a dangerous activity and safety is a major concern. Post accident pathology is an essential tool of determining the cause of death of the pilot, types of injuries, possible physiological problems that contributed to the accident and finally, possible solutions to improve safety. The aircrew injuries of 151 Class-A accidents, of the Hellenic Air Force, in the last 20 years is presented. Accidents were divided, according the aircraft type, in three groups: Jet Aircraft Accidents, Fixed Wing Props Accidents and Helicopter Accidents. In the Jet Aircraft group, a subdivision was made in three more subgroups: Non ejection attempted, successful ejection and unsuccessful ejection. In all groups the type and location of injuries was recorded, and the results were discussed. An attempt was made to give possible solutions. Injury data bank of aircraft accidents can be very useful in improving accident investigation techniques and safety and more data must be recorded. Author
