GENERAL INSTRUCTIONS FOR COMPLETING SF 298

The Report Documentation Page (RDP) is used in announcing and cataloging reports. It is important that this information be consistent with the rest of the report, particularly the cover and title page. Instructions for filling in each block of the form follow. It is important to *stay within the lines* to meet optical scanning requirements.

Block 1. Agency Use Only (Leave blank).

Block 2. Report Date. Full publication date including day, month, and year, if available (e.g. 1 Jan 88). Must cite at least the year.

Block 3. Type of Report and Dates Covered. State whether report is interim, final, etc. If applicable, enter inclusive report dates (e.g. 10 Jun 87 - 30 Jun 88).

Block 4. Title and Subtitle. A title is taken from the part of the report that provides the most meaningful and complete information. When a report is prepared in more than one volume, repeat the primary title, add volume number, and include subtitle for the specific volume. On classified documents enter the title classification in parentheses.

Block 5. Funding Numbers. To include contract and grant numbers; may include program element number(s), project number(s), task number(s), and work unit number(s). Use the following labels:

C - Contract	PR - Project
G - Grant	TA - Task
PE - Program Element	WU - Work Unit Accession No.

Block 6. Author(s). Name(s) of person(s) responsible for writing the report, performing the research, or credited with the content of the report. If editor or compiler, this should follow the name(s).

Block 7. Performing Organization Name(s) and Address(es). Self-explanatory.

Block 8. Performing Organization Report Number. Enter the unique alphanumeric report number(s) assigned by the organization performing the report.

Block 9. Sponsoring/Monitoring Agency Name(s) and Address(es). Self-explanatory.

Block 10. Sponsoring/Monitoring Agency Report Number. (If known)

Block 11. Supplementary Notes. Enter information not included elsewhere such as: Prepared in cooperation with...; Trans. of...; To be published in.... When a report is revised, include a statement whether the new report supersedes or supplements the older report.

Block 12a. Distribution/Availability Statement. Denotes public availability or limitations. Cite any availability to the public. Enter additional limitations or special markings in all capitals (e.g. NOFORN, REL, ITAR).

DOD - See DoDD 5230.24, "Distribution Statements on Technical Documents."

DOE - See authorities.

NASA - See Handbook NHB 2200.2.

NTIS - Leave blank.

Block 12b. Distribution Code.

DOD - Leave blank.

DOE - Enter DOE distribution categories from the Standard Distribution for Unclassified Scientific and Technical Reports.

NASA - Leave blank.

NTIS - Leave blank.

Block 13. Abstract. Include a brief (*Maximum 200 words*) factual summary of the most significant information contained in the report.

Block 14. Subject Terms. Keywords or phrases identifying major subjects in the report.

Block 15. Number of Pages. Enter the total number of pages.

Block 16. Price Code. Enter appropriate price code (*NTIS only*).

Blocks 17. - 19. Security Classifications. Self-explanatory. Enter U.S. Security Classification in accordance with U.S. Security Regulations (i.e., UNCLASSIFIED). If form contains classified information, stamp classification on the top and bottom of the page.

Block 20. Limitation of Abstract. This block must be completed to assign a limitation to the abstract. Enter either UL (unlimited) or SAR (same as report). An entry in this block is necessary if the abstract is to be limited. If blank, the abstract is assumed to be unlimited.

1.0 EXECUTIVE SUMMARY

Northeast Research Institute LLC (NERI) and ANEPTEK Corporation recently performed PETREX Soil Gas sampling at the Air National Guard Station (ANGS) in North Smithfield, Rhode Island. The purpose of the soil gas investigation was to screen the study area for the presence of benzene, toluene, ethylbenzene/xylene(s) (BTEX), trichloroethene (TCE), and trichloroethane (TCA) which may be indicative of chemical occurrences in the subsurface.

VOCs related to petroleum hydrocarbon mixtures such as gasoline, and Diesel/Fuel Oil fuel were identified in soil gas. Limited occurrences of the chlorinated solvents TCE and tetrachloroethene (PCE) were also detected. TCA was not identified in soil gas. The distributions of the gasoline and Diesel/Fuel Oil fuel mixtures were mapped by characterizing the hydrocarbon compounds detected and formulating soil gas signatures, or fingerprints, for each mixture. High soil gas response levels of hydrocarbons more likely related to gasoline (such as BTEX), were detected east of Building 110, north of Building 106 and in the vicinity of Buildings 107 and 111. The soil gas response levels detected in each of these areas may be indicative of potential source areas of gasoline release. High relative response levels for the Diesel/Fuel Oil like hydrocarbons (such as naphthalene) were detected in the vicinity of Building 109 and northwest of Building 106. The intermediate response levels for both mixtures indicate that primary migration of the hydrocarbons may have occurred following a north - south migration pathway. The hydrocarbon occurrences appear to extend beyond the survey boundaries primarily to the north, therefore the areal extent of the VOC occurrences was not defined by this investigation.

2.0 INTRODUCTION

Northeast Research Institute LLC (NERI) and ANEPTEK Corporation recently performed PETREX Soil Gas sampling at the Air National Guard Station (ANGS) in North Smithfield, Rhode Island. The purpose of the soil gas investigation was to screen the study area for the presence of benzene, toluene, ethylbenzene/xylene(s) (BTEX), trichloroethene (TCE), and trichloroethane (TCA) which may be indicative of chemical occurrences in the subsurface.

3.0 OVERVIEW OF THE PETREX TECHNIQUE

Each PETREX soil gas sampler consists of two or three activated charcoal adsorption elements (collectors) housed in a resealable glass container in an inert atmosphere.

Soil gas sample collection is performed by unsealing the sampler and exposing the collector to the soil gas of the subsurface environment at the base of a shallow borehole. Sample collection proceeds via free vapor diffusion through the opening of the uncapped sampler container. Following a controlled period of time, the sampler is retrieved from the borehole, resealed, and submitted for analysis.

One collector from each soil gas sampler is analyzed by Thermal Desorption/Mass Spectrometry (TD-MS). Selected second collectors may be analyzed by Thermal Desorption-Gas Chromatography/Mass Spectrometry (TD-GC/MS) for compound confirmation. At least ten percent of samplers used in any project are three collector samplers. The third collector is used for setting instrument sensitivity prior to analysis.

Compounds are identified by comparison to standard reference spectra run on the same instrument. The mass spectral ion count of the appropriate indicator peak(s) for each compound or group of compounds is then plotted as relative response on a map and contoured using a variety of standard geostatistical analyses.

For a more detailed and technical discussion of the method, please refer to Appendix A, PETREX Protocol.

4.0 OBJECTIVES

The purpose of the PETREX Soil Gas Survey was to:

1. Collect and report VOC's and SVOC's as constituents of soil gas;
2. Map the areal extent of the reported compounds in order to exhibit areas of potential subsurface contamination; and
3. Attempt to determine the extent of migration of the reported compounds in the subsurface.

5.0 SCOPE OF WORK

Eighty (80) PETREX soil gas samplers were utilized for this soil gas investigation. Samplers were placed in a regular pattern throughout the site on one hundred (100) foot intervals. The survey was designed by ANEPTEK to screen potential source areas including the septic leach field located south of the primary study area.

6.0 FIELD ACTIVITIES

Sampler installation was performed between October 13th and 17th, 1994, sampler retrieval was performed on November 2nd and 3rd, 1994. Sampler installation and retrieval was performed by ANEPTEK personnel following one day of on-site training in the methods and protocols associated with performing a PETREX Soil Gas Survey.

Sampler exposure time was determined by the use of exposure time test samplers (time tests). Time test samplers were installed concurrently with the survey sampler installation and removed for analysis following a three (3) day exposure period. The purpose of the time test samplers was to assess the loading rate of Volatile Organic Compounds (VOCs) and Semi-Volatile Organic Compounds (SVOCs) onto the PETREX collectors. Based upon the analyses of time test samplers, 16 days was determined to be an optimum exposure period.

7.0 METHOD QA/QC

7.1 Lot Control

Quality assurance/quality control (QA/QC) collectors from each lot manufactured by NERI were analyzed by TD-MS to ensure that they were contaminant free before the lot of collectors used in the field was released from the PETREX laboratory. No compounds were detected above background on the QA/QC collectors.

7.2 Travel Blanks

Two PETREX samplers were provided as travel blanks. These travel blanks remained sealed and traveled with the survey samplers from the laboratory to the field and back to the laboratory to monitor for potential contamination of the survey samplers. The travel blanks were analyzed under the same instrument conditions as the survey collectors. The results of the analysis of the travel blanks are provided in Table 1, Appendix B.

A more detailed description of the PETREX QA/QC may be found in the PETREX Protocol located in Appendix A.

8.0 RESULTS

All samplers were analyzed by NERI's standard method of Thermal Desorption/Mass Spectrometry (TD-MS). The results of the analyses indicate that petroleum hydrocarbon mixtures related to both a gasoline and Diesel/Fuel Oil mixture were the most prominent compounds detected in soil gas. The distributions of the gasoline and Diesel/Fuel Oil fuel mixtures were mapped by characterizing the hydrocarbon compounds detected and formulating soil gas signatures, or fingerprints, for each mixture. In order to report the compounds identified, mass spectral peaks indicative of the compound mixtures were selected and their corresponding ion counts were summed. Table 2 lists the mass peaks (indicator peaks) which were used to represent the petroleum hydrocarbon mixtures reported in Table 1, Appendix B, and Plates 2-3, Appendix D.

TABLE 2
REPORTED COMPOUNDS AND THEIR INDICATOR MASS PEAKS (AMU)

<u>Compound</u>	<u>Indicator peak</u>
Gasoline Mixture	
C ₆ -C ₁₀ Aromatic Hydrocarbons	78, 92, 106, 120, 134
Diesel/Fuel Oil Mixture	
C ₉ -C ₁₄ Aliphatic Hydrocarbons	123, 137, 151, 165, 181, 195

In addition to the compounds reported above, limited occurrences of TCE and PCE were also identified. The locations and relative response of these occurrences are reported in Table 3, Appendix B.

Example mass spectra of the mixtures identified in this soil gas investigation are provided as Figures 1-4, Appendix C. A mass spectrum of a representative travel blank is shown in Figure 5.

9.0 DISCUSSION

The soil gas response levels discussed in the following section are described as high and intermediate relative to the entire data set. The ion count values that have been reported represent qualitative soil gas values that were evaluated relative to the other sampler locations.

The response values are reported in ion counts. Ion count values are the unit of measure assigned by the mass spectrometer to the relative intensities associated with each of the reported compounds. These intensity levels or response levels do not represent an actual concentration of the reported compounds; however, they are best utilized as a qualitative measurement. A difference in ion count values of an order of magnitude or more is considered

significant when interpreting potential source areas and migration/dispersion pathways versus background areas.

The contour intervals depicted on Plates 2-3 were determined using histograms formulated from the statistical distribution of the data set. The histograms used to determine the sample population breaks are provided as Figures 1-2, Appendix D.

For a complete discussion of relative response map evaluation, please refer to the PETREX Protocol, Appendix A.

9.1 The Distribution of The Gasoline Mixture

The distribution of the Gasoline Mixture is shown on Plate 2, Appendix E. High soil gas response levels of the gasoline range hydrocarbons were detected in the vicinity of Building 110, north of Building 106 and in the vicinity of Buildings 107 and 111. The soil gas response levels detected in each of these areas may be indicative of potential source areas of gasoline release. Several spatially continuous samples exhibiting high response levels were detected east of Building 110 in a north - south trending pattern. The responses detected in this area may indicate a primary potential source in this area. Intermediate response levels, which generally depict migration patterns, for the gasoline mixture were detected throughout the central portion of the study area, and also appear to follow a north-south migration pathway. The intermediate response levels detected in the vicinity of Building 106 indicate that migration is limited to this vicinity. The intermediate response levels detected in the vicinity of Building 111 indicate that migration may have occurred towards the northeast. Isolated occurrences of intermediate response were also identified in the vicinity of Buildings 104 and 105, west of Building 108 and at a single location in the leach field. The environmental significance of these apparently separate occurrences is difficult to ascertain, however the response levels detected at these locations are not those generally indicative of potential source areas. The distribution of the gasoline mixture extends beyond the survey boundaries to the north, east and potentially to the west and was not defined.

The identification of the aromatic hydrocarbons was not possible at several sample locations due to interference associated with terpenes. Terpenes are naturally existing vegetative compounds sourced predominantly from pine trees, whose mass fall within the same mass range as several petroleum hydrocarbons. The samples in which interference by terpenes masked the identification of the gasoline range hydrocarbons have been denoted by a "T" on Tables 1, Appendix B, and Plate 2, Appendix E.

9.2 The Distribution of The Diesel/Fuel Oil Mixture

High relative response levels for the Diesel/Fuel Oil hydrocarbons were detected in the vicinity of Building 109, northwest of Building 106 and at a single location southeast of Building 110. The intermediate response levels detected indicate a north-south preferential migration pathway.

Isolated occurrences of the diesel/fuel oil mixture were also detected east and southeast of Building 104, and east of Building 111.

10.0 CONCLUSIONS

VOCs related to gasoline and diesel/fuel oil petroleum hydrocarbon mixtures were detected in soil gas at this site. In addition limited occurrences of TCE and PCE were detected. The distributions of the hydrocarbon mixtures were mapped and potential source areas were identified. The primary potential source area of gasoline release appears to have been identified in the vicinity located east of Building 110. The primary potential source area of diesel/fuel oil release appears to have been identified in the area located west of Building 109. A preferential migration pattern trending north-south appears to exist for both compound mixtures. The areal extent of hydrocarbon occurrences extends beyond the survey boundaries, and was not defined by this investigation.

The distribution of the compounds which comprise the diesel/fuel oil soil gas mixture is less extensive than that of the aromatic compounds which define the gasoline mixture. The aliphatic compounds are much less mobile in the subsurface due to their chemical structure and lower mobility. Conversely the higher solubility and mobility of the aromatic compounds tend to illustrate the extents of chemical migration.

Because soil gas emanation rates are site and chemical specific, the environmental significance of the soil gas response values must be determined relative to compound concentrations in subsurface soil and/or groundwater. Changes in soil gas response in orders of magnitude may be used to plan future investigative studies, and to aid in characterizing the behavior (migration, attenuation) of the chemicals in the subsurface. The PETREX method is extremely sensitive and often detects compounds in the low part per billion (ppb) range; therefore areas depicted as background by the PETREX method generally do not represent environmentally significant contaminant levels in the subsurface.

11.0 RECOMMENDATIONS

Based upon the findings of the PETREX soil gas survey, NERI recommends:

1. Performing an extended PETREX soil gas survey in directions in which chemical occurrences appear to extend beyond the limits of this investigation. The data obtained from this follow up investigation can be used to determine additional potential source areas and define the areal extent of migration.
2. Perform subsurface profiling in the vicinity of sample locations 21, 24, 25, 30, 33, 36, 41, 45, 48, 53, 60 and 62. Soil and groundwater analyses should include methods which detect aromatic and aliphatic hydrocarbons as well as chlorinated hydrocarbons.

12.0 LIMITATIONS

This report represents NERI's professional interpretation and judgment based on technical information gathered during investigative activities. Professional judgments expressed herein are restricted to facts available within the established limits of the scope of work, budget, and schedule. NERI assumes no responsibility for the existence or disclosure of conditions which did not come to its knowledge, or conditions not generally recognized as environmentally unacceptable, at the time this report was prepared.

It is NERI's specific intent that all observations and conclusions presented will be used as a guide and not necessarily a firm course of action unless explicitly stated as such. No warranties are expressed or implied and the information included in this report is not to be construed as legal advice.

APPENDIX A
PETREX Protocol

PETREX ENVIRONMENTAL SOIL GAS PROTOCOL

INTRODUCTION

The PETREX Technique provides a means by which trace quantities of gases from subsurface derived organic contaminants can be detected and collected at the earth's surface. The Technique is integrative, thereby eliminating the short-term variations associated with other gas/vapor detection methods. The PETREX Technique directly collects and records a broad range of organic compounds emanating from subsurface sources.

SOIL GAS COLLECTOR PREPARATION

Adsorption collector wires (after construction) are cleaned by heating to 358° C in a high vacuum system. Wires are packed under an inert atmosphere in glass culture tubes. One collector out of every batch of thirty is checked for cleanliness by mass spectrometry. Another collector from the batch is checked for adsorptive capability. Based on the results, the batch of collectors is approved for release into the field.

SOIL GAS SAMPLER INSTALLATION

The sampler consists of two or three collectors, each a ferromagnetic wire coated with an activated charcoal adsorbent in a screw top glass culture tube. Each sampler is typically placed in a shallow hole, 14-18 inches deep. The hole is backfilled and the location is marked. The sampler is left in the ground from one to thirty days, then retrieved and sealed for transportation back to the laboratory for analysis.

The PETREX soil gas sampling technique is adaptable to various surface conditions commonly encountered within survey areas. These surfaces typically include concrete, asphalt, grass, and gravel. Two installation methods are routinely utilized to adapt to these surface conditions.

The first method utilizes a coring shovel for sampler installations in grass or otherwise loosely consolidated soil conditions. The shovel cores a 14 inch deep by 2 inch diameter hole in the surface soils.

PETREX soil gas samplers are placed (open end down) at the bottom of each core hole. The samplers are then backfilled with an aluminum foil plug and the original excavated soil. To complete installation, sample locations are marked with ribbon flagging and a numbered pin flag, as well as entered into a field notebook and plotted on a field map.

The second method of sampler installation utilizes an electric rotary hammer, equipped with an 18 inch by 1.5 inch diameter drill bit, for sampler installations under concrete, asphalt, or otherwise consolidated conditions. A hole is drilled through the surface to the dimensions of the drill bit equipped to the rotary hammer.

PETREX soil gas samplers are placed at the bottom of each drilled hole. For retrieval purposes, a cleaned galvanized steel wire is attached to each sampler. Aluminum foil is used to plug each hole to approximately two inches below grade. Then each hole is capped to grade with hydraulic cement. The hydraulic cement serves as protection from the external surface environment.

To complete sampler installation, sampler locations are marked with paint (where applicable), entered into a field notebook, and plotted on a field map.

SOIL GAS SAMPLER RETRIEVAL

PETREX soil gas samplers are retrieved following a time period that has allowed for the soil gas emanating from the subsurface environment of a survey area to equilibrate with the installed PETREX samplers. This time integration period is determined for each PETREX soil gas survey based on time calibration data or site conditions.

Retrieval operations are dependent on surface conditions and routinely consist of the following two methods.

The first method applies to grass covered or loosely consolidated soil conditions. A trowel is utilized to expose the backfilled samplers; then with a pair of tongs, the samplers are brought to the surface. At the surface, the samplers are sealed, cleaned, and labeled. Following retrieval, all debris are gathered and the core hole is backfilled with original material.

The second method applies to concrete, asphalt, or other consolidated surface conditions. A hammer and chisel is utilized to remove the hydraulic cement plug and expose the sampler. By means of the pre-attached retrieval wire, the sampler is brought to the surface. At the surface, the retrieval wire is removed and the sampler is sealed, cleaned, and labeled. Following retrieval, each drill hole is backfilled and patched with cement or asphalt.

TIME CALIBRATION SAMPLERS

Time calibration samplers are included in PETREX soil gas surveys, as appropriate. These samplers are included as a means of monitoring the loading rates of volatile and semivolatile organic compounds (VOCs and SVOCs) emanating from the soil gas at a survey area onto the PETREX collectors.

During PETREX sampler installation, two sets of three to five time calibration samplers are also installed at survey sample locations that best represent the range of soil gas response for the survey area. These representative locations are determined based on previous soils and/or groundwater studies and other site specific conditions such as gradient and potential source areas.

The first set of time calibration samplers are generally retrieved within a week or less following the initial installation and the second set one week later. Often, permanent on-site personnel are instructed to perform time calibration sampler retrieval.

Lengths of exposure periods of the survey samplers for each survey are determined based on the results of each respective set of time calibration samplers. Time calibration samplers are usually analyzed within 24 hours upon receipt at the laboratory. At the first indication of significant relative ion count intensities and significant total ion count values, the decision is made to retrieve the entire complement of survey samplers.

If there are no significant relative ion count intensities detected from the second set of time calibration samplers, then the survey samplers are allowed to equilibrate in the field for a maximum time period of up to 30 days. The average environmental PETREX soil gas survey requires a collector integration period of one day to two weeks.

METHOD QA/QC

Within every survey sampler, the two or three collector wires should have adsorbed identical compounds. Like compounds on separate collectors relate an acceptable quality assurance (QA) during the survey's analysis. The first wire is analyzed by Thermal Desorption/Mass Spectrometry (TD/MS). The data from the first wire is reported on the relative response maps. The second wire is retained for analysis by Thermal Desorption-Gas Chromatography/Mass Spectrometry (TD-GC/MS), if warranted by the initial TD/MS analysis of the second wire.

Approximately ten percent of the total PETREX survey samplers contain three collector wires. The third collector wire, a QC collector wire, is used by the operator to test the mass spectrometer's operating conditions prior to survey analysis. Some of these quality control (QC) collectors are also used to check the mass spectrometer sensitivity during survey analysis. In addition, the QC collector may be used to compare the reproducibility of the detected VOCs.

TRAVEL BLANKS

Two PETREX samplers, each containing a single collector wire, are included with each PETREX soil gas survey as travel blanks. These blanks are analyzed with the survey samplers to indicate whether there may have been contamination introduced to the survey samplers during installation or shipment. If compounds other than normal atmospheric (e.g., CO₂, H₂O, N₂, and Ar) are detected on the blanks, these results are taken into consideration in the data presentation. This process, an initial step to data interpretation, involves the correction of ion count values of the detected blank contaminants from the entire survey's data set. The resulting ion count values are provided on the relative response maps.

MASS SPECTROMETER TUNING

An Extranuclear Quadrupole C-50 Mass Spectrometer or similar instrument, equipped with a Curie-point pyrolysis/thermal desorption inlet, is used for collector analysis. Mass assignment and resolution are manually adjusted using a Perfluorotributylamine (PFTBA) standard or a built-in tuning program, depending on the instrument. A linear correction, based on the known spectrum of PFTBA, is calculated. This correction is applied to a second PFTBA spectrum. If correct mass (M/Z) values are obtained, the operator proceeds to the next tuning step. If not, Step 1 is repeated until correct masses are obtained.

Peak intensity ratios are set from the major peaks in the PFTBA spectrum using the following values:

Mass (M/Z)		Spectrum Intensities
69	=	100%
131	=	48% $\pm$ 5%
219	=	50% $\pm$ 5%

During tuning, the ion signal for mass (M/Z) 69 of PFTBA is measured at a preset sample pressure and detector voltage and compared to previous values at the same setting.

Electron energy is set to 70 electron volts. All other operating parameters, such as scans, scan range, and mass offset, are established in the computer program. These values may only be changed by the laboratory manager.

Tuning is performed at the beginning of a run so that an individual survey is analyzed at the same set of instrument conditions. The samplers are analyzed in random order.

LABORATORY ANALYSIS

Periodic machine background and blank PETREX collector analyses are performed to assure that there is no carry-over between successive collectors. If there are peaks present which are not related to atmospheric gases, the supervisor is notified and the mass spectrometer is shut down and cleaned as necessary.

A written sample number record is kept during the analysis to prevent accidental cross numbering. The mass spectrometer control program contains appropriate "flag statements" that prompt the operator with a warning if an input sample number has already been analyzed. The operator then checks the current number, along with the disk storage location of the previously entered number to identify the true numbering situation.

COMPOUND IDENTIFICATION

Compound identification is based on molecular weight, compound fragmentation, and isotope distribution, as applicable. Each VOC exhibits a unique mass spectral signature. NERI maintains a large library of spectra of individual compounds, accessible by computer. In addition, the company maintains a large library of mass spectra of commonly used chemical mixtures; e.g., gasolines, diesels, industrial oils and solvents, coatings, plastics, etc. These spectra are used to assist in both compound and mixture identifications.

The ion count response of an indicator peak(s), representative of the compound and away from interference by other compounds, is extracted for data presentation and mapping.

INTERPRETATION OF SOIL GAS DATA

Soil gas data (including PETREX) reflect volatile and semivolatile organics collected at a point in the near surface. The sources of these volatile organics may be in the stratigraphic column and/or in groundwater below the collection point. Thus, the organics can be derived from surface spills, deposition, or migration into the deeper vadose zone, and groundwater. The soil gas survey reveals the areal extent of contamination and is the optimum guide in identifying areas in order to develop a vertical profile, including the drilling of soil borings and monitoring wells.

Soil gas data are always semi-quantitative in that multiple sources in soil and/or groundwater cannot be differentiated. However, the higher ion responses are representative of higher concentrations in the subsurface, given that geologic conditions are relatively consistent.

Due to chemical differences between individual compounds, including their ability to both adsorb and desorb from the charcoal PETREX collector element, it is invalid to compare the ion count of a compound at one sampling location to that of another compound.

APPENDIX B

Notes:

1. The C6-C10 aromatics were summed to represent gasoline.
2. The C9-C14 aliphatic hydrocarbons were summed to represent diesel/fuel oil.
3. ND = Not Detected
4. The presence of naturally occurring aromatic terpenes, a class of compounds generated by vegetation, masked the identification of gasoline aromatics. However, review of the mass spectra suggests that there were no other hydrocarbons present that would indicate the presence of gasoline.

**FIELD GAS CHROMATOGRAPHY PROJECT
SOIL HEADSPACE ANALYSIS
North Smithfield Air National Guard Base
Slatersville, Rhode Island**

INTRODUCTION

ECT has completed a Field Gas Chromatography Project at the above-referenced property (SITE) at the request of Mr. Jeffrey Healey of ANEPTEK Corporation (Client). This report is subject to the Limitations attached in Exhibit A.

This Field Gas Chromatography Project was conducted between November 29 and December 6, 1994, in order to identify volatile hydrocarbons and chlorinated solvents, specifically benzene, toluene, ethyl benzene, xylenes (BTEX), trichloroethene (TCE), 1,1,1-trichloroethane (TCA), dichloroethene (DCE), and perchloroethene (PCE), in sample headspace from soil samples collected at the SITE. ECT tested 40 soil samples on SITE (see RESULTS in TABLE 1) provided to ECT by the Client. A set of the sample chromatograms are provided in Exhibit B.

INSTRUMENTATION

An SRI Model 8610 gas chromatograph (GC), equipped with a 15-meter capillary column and photoionization detector (PID) was used to analyze samples on SITE. Data was acquired with an SRI Peak II computer-based software system.

METHODOLOGY

Method blanks and standards were analyzed daily to maintain quality control. A calibration was established based upon a standard prepared with BTEX, TCE, TCA, DCE, and PCE obtained from Supelco, Inc.

Identification of the analytes is based on a comparison of the retention times for the detected peaks against those associated with the calibration standard. Calibration standards were generally analyzed at the beginning and end of each day, after 8 to 10 samples, and after a transfer of the mobile laboratory to a new Area of Concern (AOC).

Page 2
North Smithfield ANG
Slatersville, Rhode Island
ECT Job #ANEPT.01446L3

Quality Assurance/Quality Control

In order to evaluate the precision of the sampling and analytical methodology, samples of a 21.75 ug/l of benzene to 41.5 ug/l of perchloroethene calibration standards were analyzed at the beginning and end of each day as well as after every 8 to 12 samples analyzed. The concentration for toluene in the standard samples ranged from a low of .134 mg/l to a high of .171 mg/l (relative percent difference range of 12.2 to 12.9 %) while the total xylenes concentration ranged from a low of .732 mg/l to a high of .961 mg/l (relative percent difference range of 13.5 to 14.1 %).

Soil Samples

Approximately 2 mls of each soil sample were collected by the Client and associated sampling subcontractor, from split-spoon samples collected from the borings, and transferred into a 40 ml VOA vial containing 30 mls of distilled water. After resealing the vial, it was agitated for one minute and placed in a water bath at 40° C for five (5) minutes allowing the headspace to reach equilibrium. Subsequently, a 200 ul aliquot of sample was injected into the GC for analysis. Results were calculated as parts-per-billion (ppb).

Supporting materials follow.

LIMITATIONS

1. The conclusions and recommendations contained in this Field Gas Chromatography report are based solely on conditions that existed at the time of the survey and on the services provided, and are not based on scientific tasks or procedures beyond those described or beyond the budgetary and time constraints imposed by ANEPTEK Corporation (Client). The stated conclusions and recommendations represent the best professional judgement of Environmental Control Technologies, Inc. (ECT) and should not be construed as statements of scientific certainty. Specifically, ECT does not and cannot represent that the SITE contains no asbestos containing materials; solid waste; hazardous materials, substances, or wastes; petroleum products or other latent conditions beyond those observed during this Field Gas Chromatography report. No other warranty, expressed or implied, is made.
2. This Field Gas Chromatography report approximates environmental conditions at the SITE. Moreover, contamination and sources of contamination may not yet have manifested themselves at the time of the survey. In addition, ECT can not predict which potential issues will become actual problems, legal or otherwise, because laws and enforcement priorities may change and environmental conditions at the SITE may also change over time.
3. The analyses and conclusions in this report may be based in part upon chemical test data provided by other sources referenced herein and are contingent upon their validity. ECT did not attempt to independently verify the truthfulness, accuracy or completeness of all information reviewed or received during this study, and EDT disclaims any liability that may arise from its reliance on such information.
4. Observations were made of the SITE as indicated in this report. Where access to portions of the SITE was unavailable or limited, ECT renders no opinion as to the presence or potential presence of hazardous materials, substances or wastes, or petroleum products in those portions of the SITE.
5. This Field Gas Chromatography report did not include an investigation as to whether any and all activities performed on the SITE have been granted all required environmental permits or licenses, or are or have been conducted in compliance with any or all applicable environmental laws and regulations. Accordingly, ECT makes no representations and offers no opinions as to whether any and all activities performed thereon are, or have been, conducted in compliance with all applicable environmental laws and regulations.

6. Inspections for asbestos containing materials (ACM), airborne radon and lead paint are outside of the scope of this Field Gas Chromatography report, however, to the extent that ECT becomes aware of the potential presence of one or more of these materials as a consequence of our visual inspection or record review, ECT will report this information to Client.
7. This Field Gas Chromatography report was prepared solely for the exclusive use of Client in accordance with generally accepted scientific practices strictly for use as a preliminary environmental evaluation of the SITE, and no other party may rely upon the information contained herein. ECT acknowledges and agrees that Client may convey this report to the seller, Title Insurer or others directly associated with the transaction of the SITE. No warranty, expressed or implied, is made or extended to any such third parties, all of whom may rely upon the information in this report at their own risk and without any legal recourse against ECT, its officers, directors, employees or agents, regardless of the legal basis for their claims; provided, however, that no third party may rely upon this report unless it agrees to be bound by these terms. To the extent that any warranty is made in this Field Gas Chromatography report, it may not be assigned by Client to any other party.
8. ECT makes no guarantee, warranty, or other representation that this report will necessarily be found in a judicial process to satisfy the "all appropriate inquiry" standard set forth in the Comprehensive Environmental Response, Compensation and Liability Act, 42 U.S.C. Section 9601 et seq., or in its analogues set forth in comparable state or local statutes, ordinances, rules, or regulations.

CORPORATION

BORING LOG

Sheet 1 of 1

Boring No. SB-14/MW-02

PROJECT North Smithfield ANG
JOB NO. 94110.32
CONTRACTOR _____
DRILLER Seaboard
CONSULTANT Hager GeoScience, Inc.
LOGGED BY J. Hager

DATE 12/6/94
TIMES 11:25 am - 11:50 am
DRILL RIG TYPE 4.25" HSA, Mobil B-53
WEATHER/TEMP. partly cloudy, 50's
DEPTH TO WATER TABLE 4 FT.
after drilling 3' after 1 hour.

LOCATION N. Smithfield Air
National Guard, North Smithfield, RI
NW corner of site
GROUND SURFACE ELEVATION _____

COMMENTS Boring was planned for outside
the fence but ground was too soft
for rig access - MW-02 installed

DEPTH BELOW GRADE (FT.)	SAMPLING				SAMPLE DESCRIPTION	HNU
	(SPT) BLOWS PER 6"	PEN	REC	TYPE		
1	15	24"	8"	SPT	0 - 0.5' Pavement. Moist fill, medium dense, dark brown to brown coarse to fine sand, little coarse to fine gravel, trace silt.	N.D.*
2	10				**Tip of spoon contained brown fine sand, trace coarse to medium sand, trace to little silt, trace coarse to fine gravel.	
3	4					
4						
5					Augered through cobbles to 5'.	N.D.*
6	40	24"	21"	SPT	Wet, very dense, gray-brown fine sand, trace coarse to medium sand, trace coarse to fine gravel, trace to little silt.	
7	56					
8	60				Augered to 8.5' to install well. (see diagram for MW-02)	
9	65				End of boring at 8.5'.
