1.0 INTRODUCTION

ICF Kaiser Engineers (ICF KE) has been contracted by the U.S. Army Environmental Center (USAEC) to perform an investigation and summary of former underground storage tank (UST) sites and existing aboveground storage tanks (AST) sites located at Cornhusker Army Ammunition Plant (CHAAP) located near Grand Island , Nebraska. CHAAP was listed as a site on the National Priorities List (NPL) in 1987. This task is being performed under Contract No. DAAA15-91-D-0014, Task Order 14. This UST/AST Investigation Report for CHAAP describes the site background, technical approach, and results of investigations that have been completed.

The former UST and AST investigations were carried out in accordance with the 1995 CHAAP RI/FS Technical Plan which was approved by the USEPA Region VII and Nebraska Department of Environmental Quality (NDEQ) **(USAEC, 1995)**. In accordance with discussions between USEPA Region VII, NDEQ and the USAEC at CHAAP on July 18, 1995, it was agreed by all parties that the Army would present UST and AST investigation related data in a report separate from the Remedial Investigation (RI) Report. All UST and AST reporting and investigations at CHAAP will be conducted in accordance with the requirements of the NDEQ and the USEPA Region VII.

The purpose of this report is to present the results of sampling events and investigations related to former UST and AST sites such that determinations can be made concerning closure of the sites or requirements for additional characterization or remediation prior to closure.

1.1 REPORT ORGANIZATION

This report is organized into six sections which are briefly described as follows:

Section 1.0 Introduction

Section 2.0 Provides a discussion of site background, physical setting and a history of previous UST removals.

Section 3.0 Presents all field investigation procedures used and a discussion of regulatory criteria and quality assurance/quality control.

Section 4.0 Provides a discussion of sampling results for each site.

Section 5.0 Conclusions

Section 6.0 References

Appendices:

A Analytical Data

B Well Construction Diagrams, Boring Logs and water level data.

C UST Documentation

2.0 SITE BACKGROUND

2.1 SITE DESCRIPTION AND HISTORY

Cornhusker Army Ammunition Plant is located on an 11,936-acre tract approximately two miles west of Grand Island, Nebraska (**Exhibit 2-1**). The major components of the facility consist of five Load, Assembly, and Pack (LAP) operation facilities or load lines, two magazine munitions storage areas, a pistol range, a sanitary landfill, a burning ground, a shop area, a nitrate area, an administration area, and various support buildings **(See Exhibit 2-2)**. CHAAP was listed as a site on the National Priorities List on July 22, 1987. Per the Federal Facility Agreement dated December 20, 1989, the site is defined as "the CHAAP and any areas contaminated by hazardous substances, pollutants, or contaminants which have migrated from CHAAP" **(USEPA, 1989)**. The CHAAP was constructed and fully operational in 1942. CHAAP was a U.S. Government-owned, contractor-operated (GOCO) facility, which was constructed for the production of artillery shells, mines, bombs, and rockets for World War II and the Korean and Vietnam conflicts. The plant was intermittently operated for 30 years with the most recent operations ending in 1973. Operations at CHAAP were limited to LAP facilities for bomb production. Unlike some other Army Ammunition Plants (AAPs) solvents were not routinely used to produce the types of bombs manufactured at CHAAP. Other AAPs used brass, which required solvent rinses for processing. At CHAAP, shells were limited to iron during World War II and the Korean conflict. During the Vietnam conflict, CHAAP also manufactured microgravel mines, which contain no metal. The gravel mine production used freon 113 and lead azide.

Former UST sites are located at the five loadlines, Administration and Base Housing Area, Shop Area, Nitrate Area, and at Buildings F-3 and D-1 Dunnage Area. Above ground storage tanks (ASTs) are located at each of the five loadlines and at the Shop Area. Fifty-eight (58) underground storage tanks (USTs) are known to have been present at CHAAP according to the UST Investigative Summary (USATHAMA 1992) and interviews with the current facility personnel. These tanks ranged in size from 15 to 34,000 gallons and contained heating oil, diesel fuel, and gasoline. One tank (S-14, T1) at the Shop Area Garage may have contained solvents associated with vehicle maintenance and waste water **(USAEC, 1991a)**. Contamination resulting from this tank is addressed in the Feasibility Study (FS) for Operable Unit One (Unsaturated Zone) and Operable Unit Three.

Nine 30,000-gallon heating oil ASTs are located adjacent to the load line boilerhouses: two ASTs at each of Load Lines 1 to 4, and 1 AST at Load Line 5. The load line ASTs reportedly contained No. 6 Fuel Oil to fuel boilers. Five ASTs are also present at the Shop Area and consist of the following: Tank S-6 is a 1,000-gal AST used for storing located at the east end of Building S-6 (garage); Tanks S-32 (10,000 gallon capacity), S-34 (12,000 gallon capacity), and S-35 (12,000 gallon capacity) are located on the east side of the Shop Area and were used for storing road oil; and, Tank S-12 (577,500 gallon capacity) was used to store No. 2 diesel fuel. A five foot high secondary containment berm surrounds Tank S-12.

2.2 PHYSICAL SETTING

The following sections describe the physical setting of CHAAP and surrounding area. This discussion includes land-use, climatology, physiography and topography, soil types, geology, surface-water hydrology, and groundwater hydrology.

2.2.1 Demography and Land Use

Cornhusker Army Ammunition Plant is located in north-central Hall County, Nebraska (**Exhibit 2-1**). The population of Hall County is 48,925, of which 39,386 reside in the city of Grand Island. The economy of the area is primarily agricultural related, with lesser commerce related to manufacturing, retail and wholesale trade, services, and government (**Baird, Andrew, October 1992**, CED, Grand Island Foundation, personal communication). The city serves as a trade center for agriculture and livestock produced on ranches and farms in the area.

The land around Grand Island is intensively cultivated and most of the original prairie grass and other vegetation has been replaced by row crops such as corn and alfalfa (**USATHAMA, 1980a**). Spalding (**1988**) indicate that most of the land between CHAAP and Grand Island is used for farming, predominantly for hay and/or pasture, dryland crops, irrigated corn, alfalfa, and soybeans.

Although the facility is inactive, much of the land and buildings are leased out to various individuals and local concerns (**Wellensiek, M., 1995**). Approximately 17 mi^2 (10,774 acres) is leased out for general agricultural use as follows: 82% cropland; 15% wildlife habitat and protection areas; and 3% grazing. The majority of the cropland acreage is irrigated. Eighty-eight magazines and 25 other buildings are leased out as general storage space. The Nitrate Area and the on-post rail sidings are leased for industrial use by Cornhusker Railcar Services, Inc., a railcar refurbisher.

2.2.2 Climatology

The area has a subhumid, continental climate with relatively low precipitation, low humidity, hot summers, and cold to severe winters. The mean annual temperature is 51°F (**EEI, 1982a**). Average annual precipitation is about 24 in., approximately 80% of which falls during the spring and summer months. Droughts are not uncommon. Late summer and early autumn rains tend to be more sporadic, occurring as localized, often intense thunderstorms which may be accompanied by tornadoes (**Keech and Dreeszen, 1964**). The average annual snowfall is about 25 in., with the greatest amount usually falling during February and March. Prevailing winds are from the south in the summer and from the northwest in the winter. Summer winds are usually moderate to strong, and are accompanied by high temperatures and low humidity, which cause a rapid loss of soil moisture and a high evapotranspiration rate.

2.2.3 Physiography and Topography

The site is located near the eastern margin of the Great Plains Physiographic Province, two miles west of the city of Grand Island in south-central Nebraska. CHAAP is located approximately seven miles north of the Platte River. Several of the areas of concern in CHAAP are located in the 100 year flood plain.

The terrain is nearly level to slightly undulatory. Ground surface at CHAAP and the surrounding area slopes gently from southwest to northeast. Elevations at CHAAP range from 1,950 ft above sea level in the southwest to approximately 1,850 ft in the northeast.

2.2.4 Surface-Water Hydrology

The major source of surface water for Hall County is the Platte River, which flows northeast across the southeastern portion of the county. The Platte River, located approximately 7 miles south of CHAAP, is a braided stream with a slope of approximately 6.5 ft/mile (**Battelle, 1984**). The area around Grand Island is susceptible to spring flooding of the Platte, which reputedly led to the town's naming. The mean flow of the Platte near Grand Island for the period 1944-1980 is 1,366 cubic feet per second (cfs) (**ANL, 1985**). In the last 50 years, flows in the Platte River system have been reduced by reservoir development such that there are now occasions when there is no flow at Grand Island.

There are no perennial creeks or rivers in the study area. Ephemeral streams in or near the study area include Silver Creek and the Wood River. During the winter, discharge is low, and water in these drainages is commonly partially or completely frozen. During the summer, these streams are often dry and their tributaries typically flow only during storm events (**ANL, 1985**).

Silver Creek is the largest surface-water feature at CHAAP, crossing the northwest corner of the facility and flowing eastward along the northern boundary of the facility. It continues east and passes north of Grand Island and the Capital Heights Subdivision. All surface water at CHAAP drains either directly to Silver Creek or to man-made ditches that eventually drain to Silver Creek. Two man-made drainage ditches (East and West Drainage channels) were constructed in 1973. The East and West Drainage ditches trend in a north-south direction, west of Load Line 1 and Load Line 3, respectively. An old ditch, referred to as the Railroad Ditch, trends parallel to the railroad tracks on the eastern boundary of CHAAP (**USATHAMA, 1980a**). Smaller ditches drain into each of these larger ditches.

2.2.5 Soil Types

Soils at CHAAP area are generally developed on Quaternary windblown silts (Peorian loess) of moderately low permeability (**EEI, 1982a**) (**Exhibit 2-3**). The soils beneath most of CHAAP have moderately low permeability (10^{-4} to 10^{-6} ft/day) and tend to retain a high percentage of water from precipitation and irrigation (**USDA, 1962**). Relatively little water moves through these soils to recharge the underlying sand-and-gravel aquifer. On-post, topsoil depths range from 12 to 24 in. The soils are

generally described as dark brown to black, organic clay to silty clay, with a sharp boundary at the underlying B horizon. The topsoils in the northwest portion of CHAAP are moderately permeable and may retain a moderate amount of precipitation and irrigation water. The B horizon is more variable, ranging from light yellowish-brown, silty, stiff clay to light yellowish-brown, clayey silts. Clay layers in the B horizon vary in thickness from 3 to 15 ft. These silt/clay layers are thickest in the northwest portion of CHAAP and thin to the south and east, eventually pinching out near the eastern edge of CHAAP.

2.2.6 Geology

Hall County is underlain by generally flatlying Quaternary sediments - fluvial sands and gravels and eolian and fluvial silts and clays. These unconsolidated deposits rest unconformably on the semi-consolidated Tertiary Ogallala Formation. The Ogallala consists of lenticular, shoestring deposits of sand, silt, clay and poorly cemented sandstone, siltstone, and claystone. The Ogallala rests on relatively impermeable bedrock of Late Cretaceous age. Where the Ogallala has been entirely removed by erosion, the Quaternary deposits rest upon Late Cretaceous bedrock. The Late Cretaceous formations (Pierre Shale and Niobrara Formation) are of marine origin and dip gently to the northwest (**Keech and Dreeszen, 1964**).

The Cretaceous bedrock surface is an unconformity with moderate relief sculpted by pre-Ogallala erosion. In some areas, post-Ogallala erosion has thinned or incised channels in the Ogallala, or removed the Ogallala entirely. The post-Ogallala erosional surface controls the thickness and lithology of the overlying Quaternary deposits. Accumulations of Quaternary sediments are thicker and tend to contain a greater percentage of sand and gravel where valleys were carved into the Ogallala and Cretaceous layers (**Keech and Dreeszen, 1964**).

In the Grand Island area, four principal stratigraphic units are recognized. The nomenclature established for the local stratigraphy for the 1993 SCD will be continued in this document as follows:

Local Stratigraphy (*SCD, 1993*)	Regional Stratigraphy (*Lugn and Wenzel, 1938*)
Paleovalley Fill unit	The **Holdrege Formation** consists of fluvial sands and gravels deposited, during the Nebraskan glacial stage, which infill the erosional valleys incised in the Ogallala Formation.
Blue Clay unit	The **Fullerton Formation**, also known as the Blue Clay confining unit, is a "widespread and more or less continuous" deposit of silt and clay thought to have been deposited during the Aftonian interglacial stage.
Alluvial sand and gravel	The **Grand Island Formation** consists of fluvial sands and gravels deposited during the Kansan stage of glaciation.
Peorian loess	**Undifferentiated surficial loess**, consisting of surficial silts and clays, is primarily associated with windblown deposits of the Peorian Glacial Stage.

The post-Ogallala erosional surface is overlain by a lower Quaternary unit of paleovalley fill sands and gravels correlative with the Holdrege Formation (**Lugn and Wenzel, 1938**). This Paleovalley Fill unit ranges from 30 ft in thickness under CHAAP to greater than 220 ft further along the paleovalley axis north of CHAAP. The unit consists of silt and clay near the paleovalley margins where eolian depositional processes were prevalent, which grade into sand and gravel along the paleovalley axis where fluvial depositional processes dominated. The Paleovalley Fill unit consists of about 30 feet of clay-rich silt of eolian origin in the vicinity of Load Line 3 (see **Exhibit 2-4**).

The Paleovalley Fill unit is overlain by the Blue Clay unit. The Blue Clay correlates with the Fullerton Formation (**Lugn and Wenzel, 1938**). Named for its distinctive blue-green appearance, the Blue

Clay unit is a distinctive bluish-grey layer consisting of silty clay, clayey silt, silt, and very fine to fine sand. Previous studies have suggested that the Blue Clay is a regionally continuous confining layer (**Lugn and Wenzel, 1938**). Lithology logs, pump test data, and water quality data were evaluated in the 1993 SCD to assess the viability of the Blue Clay as a confining layer. This data was interpreted to indicate that the Blue Clay unit is laterally persistent throughout CHAAP. The Blue Clay confining unit varies in thickness from 4 ft to greater than 35 ft and is present throughout the study area at a depth ranging from 45 to 70 ft bgs.

The Blue Clay unit is overlain by laterally persistent sand and gravel deposits, averaging 40 to 60 ft in thickness. This sand and gravel unit, referred to here as the Alluvial sand and gravel unit is correlative with the Grand Island Formation (**Lugn and Wenzel, 1938**).

The uppermost geologic unit at CHAAP is the Peorian loess. This silt and clay unit is about 15 ft thick in the northwestern portion of CHAAP, beneath the Burning Grounds and Sanitary Landfill areas, and thins to less than one ft at the southern and eastern boundaries of the facility.

CHAAP is situated over a paleo-high on the post-Ogallala erosional surface, between two eastward-trending paleovalleys. The Quaternary sedimentary deposits change character from west to east across the study area, from a high on the post-Ogallala erosional surface out across the Paleovalley axis. In the western portion of CHAAP Quaternary sediments are approximately 100 ft thick, consisting of approximately 55 ft of Alluvial sand and gravel, 15 ft of blue clay, and 30 ft of Paleovalley Fill silt (see **Exhibit 2-4**, Testhole 11-11-13). The Quaternary sediments thicken to the east. At the eastern edge of CHAAP the Quaternary is approximately 170 ft thick and consists of approximately 60 ft of Alluvial sand and gravel, 5 ft of blue clay, 35 ft of Paleovalley Fill sand, and 70 ft of Paleovalley Fill silt (see **Exhibit 2-3**, Testhole G0070). Farther to the east, in the Capital Heights subdivision, the thickness of Quaternary sediments exceeds 290 ft (see **Exhibit 2-4**, Testholes CA253 and CA273). Here, the Quaternary consists of approximately 60 ft of Alluvial sand and gravel, 5 to 23 ft of blue clay, and greater than 220 ft of Paleovalley Fill sand, gravel, and silt (see **Exhibit 2-4**, Testhole CA253, CA273, and 05C). The Ogallala is present under all but the northernmost portion of CHAAP, where erosion in the paleovalleys has removed the Ogallala and incised the Cretaceous surface (see **Exhibit 2-4, 2-5 and 2-6**).

2.2.7 Groundwater

The unconsolidated Quaternary sands and gravels are the primary source for groundwater in Hall County. Deep test-hole drilling conducted as part of previous hydrologic investigations (**Keech and Dreeszen, 1964**) and as part of the 1993 SCD, lithologic logs for monitoring wells; and irrigation well driller's logs submitted to the state indicate that the Quaternary Aquifer System is divided into three hydrologic units. The upper unit is equivalent to the alluvial sand and gravel unit, and is referred to here as the Alluvial aquifer. It consists of sand and gravel with occasional silt and clay lenses and has a saturated thickness ranging from 28 to 65 ft. Beneath the Alluvial aquifer, a greenish gray to light gray, silty clay, the Blue Clay, is present. The Blue Clay confining unit varies in thickness from four feet to greater than 35 ft and is present throughout the study area at a depth ranging from 45 to 70 ft.

The lowermost hydrologic unit is the Paleovalley Fill unit, which ranges in thickness from 63 ft to greater than 290 ft and consists of alluvial sand, silt, and clay. The relative amount of sand, gravel, silt, and clay varies with respect to proximity to the Paleovalley axis. Finer-grained sands and silts are predominant at the edges of the paleovalley, while coarser sands and gravels occur in the deeper portion of the paleovalley. The Paleovalley Fill unit at CHAAP consists mostly of eolian clay-rich silt (see **Exhibit 2-3**).

The Paleovalley Fill silt is underlain by the Ogallala, which pinches out just east and north of the installation boundary. The Ogallala consists of discontinuous deposits of sand, silt and clay, which are locally poorly cemented. The Ogallala does not represent a significant water source in this area.

The Cretaceous Pierre and Niobrara Formations underlie the Ogallala and represent the base of the aquifer system. Where the Ogallala is not present, these formations underlie the Paleovalley Fill unit. These formations are extremely thick and relatively low in permeability.

Water level, water quality, and pump test data reviewed in the 1993 USAEC Site Characterization suggest that the Blue Clay unit is an effective confining layer and that the Paleovalley Fill unit is a confined

aquifer. The Alluvial aquifer is unconfined. Review of the logs of over 115 test holes, monitoring wells, and irrigation wells indicates that the Blue Clay is continuous below CHAAP. Water level data collected during the 1993 SCD from well clusters containing wells screened above and below the Blue Clay unit indicate head differences across the confining unit ranging from 0.14 to 0.59 ft.

In the vicinity of CHAAP, groundwater is typically 6 to 18 ft bgs. Available water level data for the years 1982 to 1990 collected from wells in the area surrounding the facility show that the depth to water ranged from 0.2 ft to 26.6 ft. Seasonal water level fluctuations in individual wells range from 1.6 to 8.8 ft, with most wells fluctuating 4 to 6 ft. Water levels in irrigation wells are reported to fluctuate 20 ft or more during pumping periods (**Battelle, 1984**).

Slug testing was conducted during the 1993 SCD using the Bouwer and Rice slug test methodology for unconfined aquifers. Calculated hydraulic conductivities from these tests ranged from 24 to 670 ft/day for the Alluvial Aquifer. A 24-hour pumping test was conducted nearby to the east of CHAAP and data were analyzed using AQTESOLV software. These analyses yielded the following ranges of values for the listed parameters for the Alluvial aquifer:

Transmissivity	=	T	=	11,631 - 17,899 ft^2/day
Horizontal hydraulic conductivity	=	K_h	=	242 - 373 ft/day
Storage coefficient	=	S	=	4.94×10^{-4} - 8.38×10^{-4}
Specific yield	=	Sy	=	0.077 - 0.14
Conductivity ratio	=	K_v/K_h	=	0.02 - 0.18

The following ranges of values were calculated for the Paleovalley Fill unit:

T (from drawdown data)	=	9,906 - 10,692 ft^2/day
T (from recovery data)	=	10,734 - 11,710 ft^2/day
S	=	3.218×10^{-4} - 4.786×10^{-4}
K_h (from drawdown data)	=	431 - 465 ft/day
K_h (from recovery data)	=	468 - 509 ft/day

The gradient of the water table in the Alluvial aquifer is uniformly from southwest to northeast, which is approximately parallel to the flow direction of the Platte River. Water-level data for the spring of 1990 indicate gradients of approximately 0.0007 to 0.0017. Comparison of water-level data collected during spring 1990, March 1985, February 1984, and January 1982, indicate the configuration of the water table has remained fairly constant through time. Water levels collected during January 1982 indicate that groundwater flow is to the northeast with a greater northern component of flow than in 1992 (**Exhibits 2-7 and 2-8**). Lateral shifts in equipotential lines reflect yearly variations in the amounts of recharge and irrigation withdrawal from the Alluvial aquifer.

Seasonal fluctuations of the water table occur. During most summers broad areas of drawdown occur due to nearly constant pumping in many of the approximately 2,000 wells in the region surrounding CHAAP. Therefore, water levels tend to be lowest during the summer and fall when groundwater is used heavily, and during the initial stages of water-table recovery. During nonpumping periods the water table returns to its highest seasonal level (**Battelle, 1984; ANL, 1985**). Groundwater recharge of the Alluvial aquifer occurs by seepage of streamflow, infiltration of precipitation, seepage of excess irrigation water, lateral movement of groundwater from areas west of CHAAP, and possible influx from the Ogallala aquifer in the northern and southern part of Hall County. Seasonal changes in groundwater pumpage and recharge occur over broad areas. The consequent changes in groundwater flow direction and lateral hydraulic gradients are small.

Groundwater levels were monitored throughout 1991 and 1992 for the 1993 SCD. These data, show atypically high water levels relative to historical levels, due to the unusually wet spring, summer, and fall. The greater-than-average precipitation resulted in little pumpage of the aquifer system for irrigation and a high recharge rate to the aquifer when levels normally would be dropping.

Most wells near CHAAP are completed in the Alluvial aquifer; however, some wells in the central and western parts of Hall County are completed in the underlying Ogallala Formation. Water levels indicate that head potentials during nonpumping periods are approximately the same as those in the Alluvial aquifer (**Battelle, 1984**). Although relatively few wells are completed in the Ogallala aquifer, a groundwater model of the study area by Battelle suggests that, where present, the Ogallala may be the primary source for recharge of the Alluvial aquifer during the irrigation season. This occurs by vertical movement of groundwater from the Ogallala aquifer through the overlying confining unit, and into the Alluvial aquifer.

2.3 HISTORY OF UST REMOVAL ACTIONS AT CHAAP

Fifty-eight underground storage tanks (USTs) are known to have been present at CHAAP according to the UST Investigative Summary (**USATHAMA, 1992**) and interviews with the current facility personnel. These tanks ranged in size from 15 to 34,000 gallons and contained heating oil, diesel fuel, and gasoline. One tank (S-14, T1) at the Shop Area Garage may have contained solvent associated with vehicle maintenance and waste water **(USATHAMA, 1991a)**. Mason and Hanger were reported to have removed 18 USTs prior to the Excessing Assessment (EA) investigation in 1991 (**USATHAMA, 1991**). Thirty-nine (39) USTs were removed by the USACE during a 1993 basewide UST removal. Only one UST is still in the ground - a 550 gallon heating oil tank (CY-1, T1) at the Commanders Representative office. The status and previous investigation results for each of the former USTs are summarized on **Exhibit 2-9**. All of the former UST locations are displayed in the "Exhibits" section of this report.

No records are available for 18 USTs removed by Mason and Hanger prior to 1990. According to Tom Jamieson, the Commanders Representative, no sampling was performed during these removals. The USTs were removed and the holes were backfilled with the excavated soil supplemented with clean fill. The closure status of these USTs is uncertain pending guidance from NDEQ.

During the 1991 EA investigation, a soil boring was completed adjacent to each of the 15 USTs with capacities of at least 1000 gallons. Subsurface soil samples were collected and analyzed for total petroleum hydrocarbons (TPH). Select samples were also analyzed for TAL/TCL compounds. Elevated levels of TPH (up to 6400 μg/g) were detected at nine UST locations. The three subsurface soil samples collected adjacent to Shop Area UST S-14, T1 were analyzed for TPH and TAL/TCL compounds. Low levels of TPH (up to 60 μg/g) were detected.

The USACE executed a basewide UST removal in June-November, 1993. Thirty-nine (39) USTs were removed by USACE contractor Tony's Cement Works, a Nebraska certified UST removal firm. The tanks were removed and soil samples were collected per State Title 159 regulations for UST removal. Two subsurface soil samples were collected from each excavation and analyzed for TPH. These samples were collected from each end of the UST, below the base of the tank, unless visibly stained soils were present, in which case the stained soils were sampled. Additional samples were collected adjacent to product conveyance lines and at tanks more than 25 feet long per State guidance. Three QA samples were also analyzed for BTEX compounds. Visibly stained soils were removed from the excavations and disposed of in the Grand Island Landfill. The excavations were then backfilled with non-stained soils supplemented with clean fill. No confirmation sampling was performed. UST Closure Assessment Reports (CARs) and sampling results were subsequently forwarded to the State. These reports are compiled in **Appendix A** of this report.

NDEQ issued a closure letter stating that no further action would be required for the three USTs where the USACE sampling results were non-detect for TPH (Administration Area UST A-2, T1, and Shop Area USTs A-39, T1 and T2). However, NDEQ issued form letters stating that petroleum product releases had occurred which would require further characterization and/or remediation for clean closure of UST areas containing the other 36 USTs. Where petroleum product releases have occurred monitoring wells were installed and sampled and subsurface soil samples were collected during the 1996 RI.

Notes. Data was compiled from the UST Investigative Summary (USATHAMA, 1992) and the 1993 USACE UST Removal (USACE, written communication). All USTs were reported to be of steel construction and lacked cathodic protection. There are no records of integrity testing. The only UST remaining is an active heating oil tank (CY-1) at the COR's office.

Abbreviations. TRPH = Total Recoverable Petroleum Hydrocarbons, detection limit = 40 µg/g. TPHC = Total Petroleum Hydrocarbons. ND = Not detected. ? = No information. NFA = NDEQ letter of no further action. B = Benzene, E = Ethylbenzene, T = Toluene, X = Xylenes. EA = Excessing Assessment (USATHAMA 1991). USACE = U.S. Army Corps of Engineers. NDEQ = State of Nebraska Department of Environmental Quality.

(a) Mason and Hanger UST Removals. No records are available for the 18 USTs removed by Mason and Hanger prior to 1990. No sampling was performed during these removals - the soils excavated were backfilled and supplemented with clean fill (Tom Jamieson, personal communication).

(b) USACE 1993 Basewide UST Removal. 39 USTs were removed by Omaha District USACE contractor Tony's Cement Works per State of Nebraska Title 159 - Rules and Regulations for USTs. Visibly stained soils were removed from the excavations and disposed of in the Grand Island Landfill. The excavations were backfilled with non-stained soils supplemented with clean fill. No confirmation sampling was performed. UST Closure Assessment Reports (CAR) and sampling results were forwarded to the State.

(c) Soil samples were collected from beneath the USTS (2 for most USTs, 3 for USTs > 25 ft long) and along conveyance pipelines, and analyzed for TRPH. A percentage of the samples were also analyzed for BTEX.

(d) Where the TPHC was detected, NDEQ responded to the CAR with a letter stating that a petroleum release was indicated and that NDEQ would require an investigation, and if necessary, remediation of the site in accordance with Title 118 - Groundwater Quality Standards. Where the CAR did not indicate TRPH detections, NDEQ responded with a letter stating that no further action would be required for the UST site.

(e) The NDEQ letters specify investigation/remediation for former UST sites/clusters. However, at sites/clusters where more than one USTs were removed, it is unlikely that further investigation will be required for former UST locations where TRPH was ND.

3.0 FIELD PROCEDURES AND INVESTIGATION PROGRAM

This section includes a discussion of field investigation procedures, State and Federal criteria and guidelines for contaminants and quality assurance/quality control. The performed field investigations were selected, in consultation with USAEC, USEPA, and NDEQ. The methodology, procedures, measurements, and observations required for each type of field activity conducted during the 1995 former UST and AST investigations are documented in the following sections. On-site support facilities were established at the Shop Area which is located south of Load Line 1. Office, sample preparation, and equipment storage areas were located in Building S-5. A decontamination pad with a collection sump was constructed by Building S-2. Decontamination water was drawn from Shop Area well S-003, the USAEC approved water supply.

3.1 SAMPLE IDENTIFICATION SYSTEM

All sampling locations, including miniwells and monitoring wells, were identified by an alphanumeric code. The first six digits represent the site identification: the first two characters in this code identify the study area of CHAAP where the sample was collected; the next two characters indicate the medium that was sampled, and the last two characters (numbers) indicate the site number. The final digit(s) indicate the sample number at that site.

For example, the code L2SB02-2 is read in the following manner:

L2: indicates that the sample location is from Load Line 2
SB: indicates that this is a soil sample collected from a soil boring
02: indicates that this is the second soil boring at Load Line 2
-2: indicates the second sample at that location

Groundwater samples collected from existing monitoring wells were identified by the site identification numbers assigned to these wells in the Installation Restoration Data Management Information System (IRDMIS).

3.2 SOIL SAMPLING

The characterization of the soils at CHAAP was accomplished by careful logging and sampling of surface and subsurface soils. A Site Geologist was present during all drilling and soil sample collection activities to maintain descriptive logs and collect appropriate samples for chemical and physical analysis. Samples were screened and/or prioritized in the field by visual inspection for staining or discoloration and/or with a photoionization detector (PID) as appropriate.

Soil sampling activities proceeded as follows:

a. All boring/well drilling permits and regulations, as required by the NDEQ were secured and/or complied with, and clearance of all underground utilities was arranged with appropriate plant personnel and local utility companies. Field clearances of the boring/drilling locations was performed by qualified UXO personnel where necessary.

b. Water used for auger drilling equipment decontamination was obtained from the approved USAEC water supply source (well S003).

c. Sampling and drilling was performed under direct supervision of the assigned Site Geologist.

d. All soil sampling points were located to map accuracy at the time of sample collection and the locations were marked or staked for future reference.

3.2.1 Soil Sample Acquisition Procedures

Soil samples were collected from standard hollow-stem auger soil borings. The sample acquisition technique is discussed as follows:

Hollow-stem Auger/Split Spoon Sampling. Split-spoon samples were collected at the surface and at five foot intervals per ASTM D1586-84 as the augers were advanced. Soil samples for chemical analysis and lithologic description were collected using a decontaminated stainless steel split-spoon sampler. The boring were either completed as a monitoring well or grouted to the surface. Drill cuttings, if any, were visually inspected and screened with a photoionization detector (PID). Soils exhibiting visual evidence of contamination or which yielded sustained PID readings of >5 ppm were containerized in 55-gallon steel drums as per NDEQ guidance. These drums were labeled, dated and temporarily staged at the drill site pending sampling analytical results.

Soil Sample Handling and Collection Procedures

During the sampling phase, the volatile organic samples were collected first and were transferred from the split spoon in a manner such that air space was minimized in the sample bottle. Samples for TPH analysis were then collected and containerized in a similar manner. Soil samples were packed in the appropriate sample bottles using a clean stainless steel spatula. The remaining soil to be analyzed for metals was then placed in a precleaned stainless steel mixing bowl, homogenized, and placed in the appropriate sample bottles. Each sample bottle contained a sample label, which included the project number, sample number, analysis to be performed, time, date, and sampler's initials. Disposable latex gloves were worn during all sampling activity and were changed between each sample location.

Sample labels and the chain of custody were completed following the collection of each sample. The labels were placed on the sample bottle and the bottle placed immediately into a cooler. The cooler was iced and samples kept at a temperature of 4°C. The completed chain of custody was sealed in a plastic bag inside the sample cooler.

3.2.2 Soil Sample Logging and Lithologic Description

During the advancement of the hollow-stem auger borings, the Site Geologist fully described all activities in the field boring log forms. As per USAEC geotechnical requirements (**USATHAMA, 1987a**), the following data was recorded in the boring logs at the drill site:

a. The name of the Site Geologist(s), project name, location, and site ID;

b. Depths in feet and fractions thereof (tenths of feet);

c. Soil descriptions, in accordance with the Unified Soil Classification System (USCS) and prepared in the field by the attending Site Geologist, which include the following information:

- Classification,
- USCS symbol,
- Secondary components and estimated percentage,
- Color (using Munsell Soil Color Chart),
- Plasticity,
- Consistency (cohesive soil) or density (noncohesive soil),
- Moisture content,
- Texture/fabric/bedding, and
- Depositional environment;

d. Cutting descriptions, including basic classification, secondary components, and other apparent parameters;

e. Visual estimates of secondary soil constituents (If terms such as "trace," "some," or "several" were used, their quantitative meanings were defined in a general legend);

f. Length of sample recovered for each sample interval for driven samples;

g. Blow counts, hammer weight, and length of fall for split-spoon samples;

h. Estimated depth interval for each sample;

i. Depth to water first encountered during drilling and the method of determination (Any distinct water-bearing zones below the first zone also were noted);

j. General description of the drilling equipment used, including the rod size, bit type, pump type, rig manufacturer, model, and drilling personnel;

k. Drilling sequence;

l. Any unusual problems;

m. Start and completion dates of all borings, and a chronological time-sequence of all significant events;

n. Lithologic boundaries;

o. Volatile organic vapors in surface and subsurface soil samples, as measured using a PID; and

p. Additional comments as appropriate.

3.3 GROUNDWATER INVESTIGATION PROCEDURES

Standard 4-in polyvinyl chloride (PVC) cased wells were installed as part of the freon and UST/AST investigations. Drilling activities at CHAAP proceeded as follows:

a. All well drilling permits and regulations, as required by the NDEQ were secured and/or complied with, and clearance of all underground utilities was arranged with appropriate plant personnel and local utility companies.

b. Water used for well materials and sampling equipment decontamination was obtained from the approved USAEC water supply source.

c. Monitoring well drilling and installation was performed under direct supervision of the assigned Site Geologist.

d. All wells were located to map accuracy at the time of sample collection and locations were marked or staked for future reference. The locations and elevations of all newly installed monitoring wells were surveyed.

3.3.1 Monitoring Well Installation/Construction

Monitoring wells were installed in borings drilled using hollow-stem auger techniques in accordance with USAEC geotechnical requirements (**USATHAMA, 1987a**). Applicable portions of the Nebraska Department of Health Water Well Standards (Title 178 NAC 10, 11, 12, and 13) were also followed. Wells were installed/constructed as follows:

- The well was installed through the annular space of the auger. The decontaminated well screen and casing was assembled as it was lowered down the boring. The completed well string was suspended off the bottom of the boring by a cable attached to the wellhead.
- A filter pack, consisting of 20/40 size silica sand, was placed in the annular space from the bottom of the well to a level 5-7 feet above the top of the well screen. The filter pack sand size was adjusted to accommodate geologic conditions encountered at the screened interval.
- If the completed filter pack was 5 feet or less below the elevation of the water table, a 5-ft thick bentonite seal composed of 3/8-in pellets was placed above the filter pack. If the filter

pack was completed above the water table, a minimum of 5 gallons of approved water was added to the pellets for hydration. The seal was allowed to hydrate for a minimum of 1 hour before grouting. The remaining annular space was filled with grout using a tremie pipe. Grout was composed of 20 parts Portland Type II cement and 1 part bentonite by weight, with a maximum of 8 gallons of approved water per 94-lb bag of cement.

- Monitoring wells were constructed of 4-in inner diameter (ID), flush-thread, Schedule 40 PVC blank casing, and, 0.010 factory-slotted, flush-thread, PVC screen. Bottom plugs and well caps were also constructed of Schedule 40 PVC. Glues or solvents were not used.
- A 5-ft long, 8-in diameter protective iron casing was installed over the PVC riser, extending approximately 2.5 feet above land surface and seated 2.5 feet into the well seal grout. It is vented to the atmosphere via a padlocked, hinged cap, which will prevent entry of water but will not be airtight.
- A 1/4-in diameter drainage port was installed, centered 1/8-in above the level of the internal mortar collar.
- A 6-in thick, 4-ft square gravel pad was placed around the wellhead. Steel protective posts were installed at the corners of the pad.

Exhibit 3-1 is a diagram of a typical 4-inch monitoring well construction. All wells installed to monitor former UST or AST sites were screened across the water table to allow for the entry into the well of potential light non-aqueous phase liquids. Well designations were painted on the protective casing. All locks used to secure the monitoring wells are keyed with the same key. A field notebook was kept by the site geologist during all well installations. The notebook contained, at a minimum, the following information: description and map of the drilling site, on-site personnel, all sampling/drilling activities, well construction details, and monitoring/screening results.

Drill cuttings were visually inspected for evidence of contamination and screened with a PID. Soils which exhibited visual evidence of contamination or which yielded sustained PID readings of >5 ppm were containerized in 55-gallon steel drums. These drums were labeled, dated and temporarily staged at the drill site pending sampling analytical results. Per NDEQ Division of Permits and Compliance guidance, soils which do not screen positive for contamination may be disposed of at the site.

3.3.2 Monitoring Well Development

The following data was recorded for development, as required in the geotechnical requirements:

a. Well designation;

b. Date of well installation;

c. Date of development;

d. Static water level before and 24 hours after development;

e. Quantity of water lost during drilling and fluid purging, if water is used;

f. Quantity of standing water in well and annulus (30 percent porosity assumed for calculation) prior to development;

g. Specific conductivity, temperature, pH, and turbidity measurements were taken and recorded at the start of development, after every well volume, and at the conclusion of development;

h. Depth from top of well casing to bottom of well;

i. Screen length;

j. Depth from top of well casing to top of sediment inside well, before and after development;

k. Physical character of removed water, including changes during development in clarity, color, particulates, and odor;

m. Type and size/capacity of pump and/or bailer used;

n. Description of surge technique, if used;

o. Height of well casing above or below ground surface; and

p. Quantity of water removed and removal time.

Development was accomplished by pumping the groundwater until the water was clear and the well was sediment free to the fullest extent practical. The standard monitoring wells were developed with a submersible centrifugal pump. Water was not added to the well to aid in development, nor was any type of air-lift technique used. The pump, hose, bailer and cable was decontaminated using approved procedures.

Well development began no sooner than 24 consecutive hours after completion of the well, but not longer than seven days. Development proceeded until the following conditions were met:

a. The water was clear to the unaided eye;

b. Water pH, conductivity, temperature, and turbidity stabilized;

c. The sediment thickness remaining in the well was less than 5 percent of the screen length;

d. At least five well volumes (including the saturated filter material in the annulus) plus the volume of water added during the drilling process were removed from the well; and

e. The cap and all internal components of the well casing above the water table were rinsed with well water to remove all traces of soil/sediment/cuttings.

Development water from monitoring wells was inspected for visual evidence of contamination and screened with a PID. Groundwater yielding sustained PID readings of >5 ppm or visual evidence of contamination was containerized on-site pending analytical results. Disposal of containerized development water followed NDEQ guidance on investigative derived wastes. Per NDEQ Division of Permits and Compliance Division guidance, groundwater not screening positive for contamination were discharged to ground downgradient from the well.

3.3.3 Groundwater Sampling

Groundwater sampling techniques are discussed in the following sections. Groundwater sampling of monitoring wells was conducted in the following manner:

- All equipment was decontaminated using techniques described in Section 3.1.7 prior to its delivery to a monitoring well site;
- Clean plastic sheeting was placed on the ground surrounding the well to prevent surface soil contamination of downhole equipment;
- Before purging began the water level and total depth of the well were measured using an electric sounding device as described in Section 3.1.3.5. This information, along with survey data of the height of the well stick-up, was used to determine the bore volume;

- An Enviropump was used, with attached 1.25-in OD PVC tubing, to purge the wells at pumping rates of 1-5 gpm (3.8-19 L/min);
- To ensure that formation water was being sampled, a minimum of 5 bore volumes was purged from the well using an electric pump. If the discharge was not at stable pH, temperature, specific conductance, and turbidity after 5 purge volumes were removed, purging was continued until these characteristics were demonstrated. If the well became dry before 5 volumes were removed, the well was purged dry a second time and sampling conducted as soon as sufficient water was available;
- Purging began at the top of the water column to remove stagnant water from the upper portion of the well casing. The pump was lowered progressively down the entire water column during purging. Purge water from background monitoring wells was spread over the ground surface a minimum of 15 feet downgradient of the well per NDEQ Division of Permits and Compliance guidance. Purge water from other (4-inch) monitoring wells was inspected for visual or olfactory evidence of contamination and screened with a PID. Groundwater yielding sustained PID readings of >5 ppm or exhibiting obvious odors or visual evidence of contamination was containerized on-site pending analytical results. Disposal of containerized purge water followed NDEQ guidance on investigative derived wastes. Per NDEQ Division of Permits and Compliance Division guidance, groundwater not screening positive for contamination was discharged to ground a minimum of 15 feet downgradient from the well.
- Water quality parameters including pH, temperature, specific conductance, DO, ORP, and turbidity were measured at least once for every volume of purge water removed. These measurements and other relevant information were recorded on the Groundwater Sampling Data Form;
- Sampling was conducted after 5 purge volumes had been removed from the well and water quality parameters stabilized. The Enviropump was also used for sampling. The lowest possible pumping rate was utilized. New surgical gloves were worn by personnel collecting the samples.
- Each non-pre-preserved sample bottle, except those for VOC analysis, was rinsed 3 times with formation water prior to sample collection. Sample preservation is discussed in the accompanying QAPP;
- Samples were collected according to analyte in the following order: VOCs, freon, BTEX, SVOCs, PAHs, metals, inorganics, explosives, TPH, pesticides/PCBs, herbicides, and organophosphorus pesticides. It should be noted that BTEX and TPH in soil and BTEX and petroleum distillates detections are discussed in this report. All other analyte detections were addressed in the 1996 RI.
- Sample labels and the chain of custody were completed after each sample was collected. The labels were placed on the sample bottle and the bottle placed immediately into a cooler. The cooler was iced and samples kept at a temperature of 4°C. The completed chain of custody was placed in a plastic bag and then into the cooler with the sample; and
- After sample collection was completed, water quality parameters were remeasured and recorded on the Groundwater Sampling Data Form.

3.3.4 Surveying of Well Locations and Elevation

Miniwell locations were not surveyed, but were located, and approximate coordinates established, from USGS topographic maps. Standard groundwater monitoring wells were surveyed by a Nebraska licensed professional land surveyor, who used a Universal Transverse Mercator (UTM), State Planar, or latitude and longitude grid accurate to within ±3 feet to establish the well's map coordinates. Additionally, elevations for the natural ground surface at each well and the top of the PVC casing was determined to within ±0.01 foot using the National Geodetic Vertical Datum of 1929. The monitoring well elevation survey was conducted within a 5-week period after the last well had been installed at the site.

3.3.5 Water Level Measurements

Water levels of surveyed wells were measured relative to the ground surface and were recorded to the nearest hundredth of a foot.

- Water levels and total well depths were measured using an electric sounding device. The tape was rinsed with water from the approved source, cloth-wiped, and allowed to air dry between consecutive water level measurements. All measurements of the depth to groundwater were referenced to a permanently marked reference point on the top rim of the monitoring well PVC casing.

The water level and total depth of miniwells were measured as part of the pre-sample purge.

3.4 DECONTAMINATION PROCEDURES

All equipment that came into contact with potentially contaminated soil, drilling fluid, water, or other material was decontaminated prior to use at each sampling location. Decontamination water was drawn from Shop Area well S003, the USAEC approved water source. Decontamination procedures for field equipment are described in the following sections. All equipment was thoroughly decontaminated before use and between sampling locations.

Drilling Equipment

- All drilling equipment, including the drill rigs, augers, and drill rods, were steam cleaned with USAEC approved water. All downhole equipment, including geoprobe rods, augers, drill rod, and samplers were then triple rinsed with deionized water. Decontaminated equipment was stored on clean pallets or plastic sheeting in a designated area of Building S-5. Equipment stored for long periods was covered with clean plastic sheeting or placed in clean plastic bags.

Well Construction Materials

- All well construction materials including casing, screen, and caps were steam cleaned and rinsed with deionized water prior to installation. All material such as labels, stickers, etc. were removed from the construction materials;

Other Sampling Materials

- Stainless steel bowls, split-spoons, and other soil sampling equipment were cleaned with USAEC approved water and Alconox, triple rinsed with deionized water, allowed to air dry, and wrapped in aluminum foil.
- Exterior surfaces of submersible pumps and hoses were cleaned by an alconox wash and triple rinsing with deionized water. Interior parts of the pump and hoses were cleaned by purging a minimum of eight gallons of USAEC approved water through the pump and hose.
- Measuring tapes, probes, transducers, and other measuring equipment were cleaned in an alconox wash and triple rinsed with deionized water.
- In sample areas where petroleum hydrocarbon products are known or suspected of being present, sample equipment was washed with an alconox water mixture and then rinsed with deionized water.
- Decontaminated equipment was stored on clean pallets or plastic sheeting in a designated area of Building S-5. Equipment stored for long periods was covered with clean plastic sheeting or placed in clean plastic bags.
- Monitoring equipment was protected from contamination to the extent possible using a protective covering such as a plastic bag. Any direct contamination was removed with a disposable wipe.

3.5 SAMPLE PREPARATION AND SHIPPING

Samples were returned to the sample preparation area in Building S-5 at the end of each day. The samples were prepared by the site personnel for shipment to the laboratory in the following manner:

- Sample bottles were removed from the field cooler and inspected for integrity;
- Labels and chains of custody were inspected for completeness;
- Sample bottles were wrapped with bubble wrap;
- The bottom and sides of a clean cooler were lined with bubble wrap or styrofoam packing material;
- Samples were placed in the cooler using additional bubble wrap between bottles to provide a snug fit;
- Double-bagged ice or blue ice sealed in zip-lock bags was placed above the sample bottles;
- Additional bubble wrap or styrofoam packing material was placed above the blue ice to fill any remaining space in the cooler;
- The Chain-of-Custody forms was placed in a zip-lock bag and the bag was taped to the inside of the cooler lid;
- The lid was secured to the cooler with duct tape and custody seals attached; and
- ICF KE personnel delivered the cooler(s) to the shipping agent.

3.6 STATE AND FEDERAL CRITERIA AND GUIDELINES TO BE CONSIDERED

In this section, State of Nebraska and Federal criteria and other criteria or guidelines to be considered (TBC) for UST and AST sites are discussed.

3.6.1 Criteria and Guidance for Groundwater at CHAAP

Guidance for groundwater applicable to the CHAAP UST/AST Investigation include:

- Federal MCLs for BTEX
- Nebraska Groundwater Quality Standards for BTEX

In the State of Nebraska, groundwater cleanup standards protective of groundwater classifications are based on the principal usage as established pursuant to the Nebraska Groundwater Quality Standards (Title 118, Chapter 4, Section 002). Federal and State Criteria for groundwater are shown in **Exhibit 3-2**.

3.6.2 Guidance to be Considered for Soil at CHAAP

To-be-considered guidance for soil at CHAAP include:

- Petroleum Contaminated Soils Protocol for the Leaking Underground Storage Tank Program, issued by Nebraska Department of Environmental Quality, LUST/ER Section
- Action Levels as recommended by USAEC, USEPA and NDEQ. USEPA Region III Risk Based Concentrations (RBCs) were also used to compare to site soil data as a means of focusing the discussion (**USEPA, 1995a**).

Petroleum contaminated soil cleanup levels are site-specific. Typical cleanup levels are 0.005 - 50 µg/g for benzene, 1 - 10,000 µg/g for total BTEX and 10 - 500 µg/g for TPH. Soil Cleanup levels are based on a site scoring system using the following site specific criteria 1) Distance to the nearest water well 2) depth to groundwater 3) Predominant soil type 4) type of contaminant and 5) distance to the nearest subsurface structure. It should be noted that BTEX concentrations determine whether or not remedial action is warranted. Total petroleum hydrocarbons do not drive cleanup of UST/AST contaminated soil.

3.7 QUALITY ASSURANCE/QUALITY CONTROL

This section has been developed from the 1996 RI Report to reflect only those samples collected to investigate former UST sites and AST sites at CHAAP.

3.7.1 Overview of Quality Assurance Program

An independent QAPP was developed in conjunction with the Field Sampling Plan (FSP) for the 1995 RI/FS of the CHAAP. The Quality Assurance Project Plan (QAPP) for the CHAAP RI/FS was implemented through the integration of well defined quality control elements for activities associated with the task assignment. The quality control criteria defined for sampling and analysis activities were developed in conjunction with specifications contained in the USATHAMA Installation Restoration Quality Assurance Program, (IRQAP) (**USATHAMA, 1990**). In addition, elements of the USEPA Interim Final Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA, (**USEPA, 1988**) were used, when approved by USAEC. In cases where these two guidance documents were in conflict, the more stringent requirement was selected. Therefore, the Quality Assurance/Quality Control (QA/QC) procedures and criteria used met or exceeded USAEC IRQAP and USEPA requirements.

All previous 1991 EA, 1993 SCD and 1994 OU1 was retrieved from the USAEC IRDMIS database system. Data retrieved from IRDMIS has been reviewed by USAEC chemists in accordance with the USATHAMA QA Program and USAEC validation guidelines.

3.7.2 Review of Documentation

Documentation required for this project was reviewed and deficiencies, if any, were identified. Documentation required by the QAPP includes the following:

- **Field Logbooks:** Hardback logbooks with numbered pages were used to log daily activities, and data collected during the course of field activities. Designated logbooks were also used to record calibration records and equipment maintenance as they were performed. Entries into field logbooks were evaluated for completeness and accuracy.
- **Field Parameter Forms:** Documentation of collected samples was provided to the laboratory on parameter forms developed specifically for USAEC investigations. Field Parameter Forms were filled out based on information recorded in field logbooks and were completed at the time of shipment to be included with the Chain-of-Custody for every sample, including QC samples. The completed forms contained all required information for encoding chemical data into IRDMIS.
- **Well Development Forms:** Field measurements (conductivity, pH, and temperature measurements) collected during well development were recorded on well development forms. A review of these forms indicates that pertinent information was recorded. Entries were evaluated for accuracy and completeness.
- **Groundwater Purge Forms:** During groundwater sampling, well purging data was recorded on the Groundwater Purge Form. Information included date, time, water quality measurements, volume of water extracted, and a description of water removed.
- **Chain of Custody:** Samples were collected and relinquished under stringent chain-of-custody protocols as specified in the project quality control plan. A review of Chain-of-Custodies indicates that all information was correctly supplied.
- **Document Control:** Documents generated in support of project activities were input into the ICF Kaiser Document Control System. A unique control number was assigned to each document prior to its being archived into the system. Access into and out of the document control system was restricted to designated personnel.

Sampling activities were performed in compliance with standard operating procedures (SOPs) and each individual performing sampling was aware of the requisite protocols for collection of environmental samples. Each geologist was experienced in drilling techniques, monitoring well installation, characterization of soil samples, and subsurface soil sampling techniques. Team members were provided with copies of the associated FSPs, QAPPs, and Health and Safety Plans.

3.7.3 Analytical Services

The analytical services for the project were provided by the following laboratories:

- **ESE Laboratory, Gainesville, Florida**: ESE Laboratory used both USAEC-performance demonstrated and USEPA-CLP methodologies in providing analytical support for this project; and
- **ESE Laboratory, Denver, CO**: ESE Laboratory used both USAEC-performance demonstrated and USEPA-CLP methodologies in providing analytical support for this project.

Two analytical programs were used for the analyses of samples for the RI/FS and are summarized in **Exhibit 3-3**. The CRLs and associated URLs are provided in **Exhibits 3-4 through 3-8.**

3.7.4 Data Reduction and Validation

3.7.4.1 USEPA Methods.

Data obtained using USEPA methods were validated by the ICF QA Manager. Results were assessed for accuracy and precision of laboratory analysis to determine the limitations and quality of data. Guidelines for the validation of data were provided by Laboratory Data Validation National Functional Guidelines for Evaluating Organic Analyses (**USEPA, 1994c**) and the Laboratory Data Validation National Functional Guidelines for the Evaluation of Inorganic Analyses (**USEPA, 1994a**). The data validation report for PAHs using USEPA SW-846 method 8310 is presented in Appendix A.

3.7.4.2 USAEC Methods.

Data obtained using USAEC Methods was validated by the contract laboratory and reviewed by the USAEC Project Chemist. Results were assessed for accuracy and precision of laboratory analysis to determine the limitations and quality of data. Guidelines for the validation of data were based on 1988 VIAR guidelines (**VIAR and Company, 1988a,b**). Weekly QC charts were reviewed by assessing trends, cycles, patterns of recovery of the quality control samples.

3.7.5 Data Review

Data obtained using both USAEC and USEPA methods were reviewed by the QA Manager to determine whether the project specific data quality objectives, as defined in the associated QAPPs, were met.

3.7.5.1 Data Quality Objectives

Data quality objectives were developed concurrently with the work plan to ensure: (1) the reliability of field sampling, chemical analyses, and physical analyses; (2) the collection of sufficient data; (3) the quality of data generated was acceptable for its intended use; and (4) valid assumptions could be inferred from the data. Attainment of data quality objectives was assessed through evaluation of all data collected using the following data quality indicators:

- **Precision** - a quantitative measure of the variability of a group of measurements in comparison to the average value;
- **Accuracy** - the bias in a measurement system;
- **Representativeness** - the degree to which the measured results accurately reflect the medium being sampled. Representativeness will be assessed based on accuracy, precision, and completeness;
- **Completeness** - the percentage of measurements which are judged to be valid; and
- **Comparability** - a qualitative parameter expressing the confidence with which one data set can be compared with another.

Data quality was assessed through the evaluation of sampling activities and field measurements associated with the chemical analytical data in order to determine the reliability of the chemical analyses and the accuracy and precision of information acquired from the laboratory.

3.7.5.2 Precision

Precision in the laboratory was evaluated during validation. Overall sampling precision was evaluated during the data review by calculating and evaluating the relative percent difference between the results of field duplicates.

3.7.5.3 Field Duplicates

Field duplicates were collected to identify the cumulative precision of the sampling and analytical process, which includes the homogenization of soil and sediment samples. Precision was checked by regularly obtaining duplicate samples for each parameter and each media. Precision will be evaluated using criteria of 50% relative percent difference (RPD) for all analyses in soil, sediment, and water matrices.

1995 CHAAP RI/FS UST and AST Sampling

Subsurface Soil: The following field duplicate subsurface soil samples were collected: T1SB1, T2SB1, and T9SB1-1. Duplicate samples were analyzed for target analytes which included BTEX and TPH. No deficiency was found for the UST/AST samples.

Groundwater: The following field duplicate groundwater samples were collected: T24GW1, and T17GW1. Duplicate samples were analyzed for target analytes which included BTEX and TPH. RPD values for all analytes were compliant.

3.7.5.4 Accuracy

Accuracy is the measure of bias in a system. This section discusses sources of error or bias due to field contamination. Sampling accuracy was assessed by evaluating the results of source water, rinse water, and trip blanks.

Analytical accuracy was reviewed during the validation of data. Analytical accuracy was assessed through the use of laboratory blanks (method and instrument) and matrix spikes. A summary of the results of the analytical review are provided in the validation summary in Appendix A.

Source Water Assessment. The sources of water used for the CHAAP RI/FS was an on-site well S0003 approved by USAEC

Source Water Analysis. The source water was collected from the USAEC approved well and analyzed and approved by USAEC, prior to use for the initial rinse and alconox scrub in the decontamination sequence. The following are the results by parameter:

- **TCL VOCs:** Non-detect (ND);
- **TCL SVOCs:** ND;
- **TCL Pesticide/PCBs:** ND;
- **TAL inorganics:** arsenic 5.72 µg/L; barium 247 µg/L; calcium 57,100 µg/L; magnesium 9,910 µg/L; potassium 10,200 µg/L; selenium 7.33 µg/L; sodium 21,400 µg/L; and vanadium 8.0 µg/L;
- **Water quality parameters:** alkalinity 170,000 µg/L; chloride 6,700 µg/L; phosphate 193 µg/L; and sulfate 32,000 µg/L;
- **Explosives compounds:** ND; and
- **Herbicides:** ND

Rinse Blanks. The blank contamination assessment was performed to determine the impact of contaminant contributions originating from non-point sources, such as field sampling equipment decontamination procedures. Rinse blank contamination assessment was completed through identifying appropriate sources of water and completing rinse blanks as required by the CHAAP RI/FS QAPP. The database generated during the CHAAP RI/FS was qualified, if necessary, using the associated field blanks. In accordance with the USEPA data validation guidelines, the detected concentration in the sample was considered a "non-detect" if the sample concentration was within five times (10 times for

common contaminants such as phthalate esters) the concentration of the associated field or laboratory blank.

Rinse blanks were collected by pouring the required volume of source water over the equipment and collecting the water in a sample container. The results of chemical analysis of the rinse blank can be used to evaluate whether the decontamination procedure has been adequately performed and whether there is cross-contamination of samples from the equipment itself. The rinse blank then accompanied the samples collected during the associated sampling sequence.

Groundwater : Four rinse blanks were associated with the samples and were analyzed for TCL VOCs, SVOCs, PAHs, pesticides/herbicides, PCBs, TAL inorganics, and explosives compounds. Based on a review of the rinse blank data, toluene should be considered non-detect in the following samples: T25GW1, and T27GW1. Indeno[1,2,3-c,d]pyrene should be considered non-detect in sample SHGW02 **(See Exhibit 3-9)**.

Surface and Subsurface Soils: Five rinse blanks were collected with the soil samples and were analyzed for the following target analytes: TCL VOCs, PAHs, SVOCs, pesticides/herbicides, PCBs, TAL inorganics, and explosives compounds. Based on a review of the rinse blank data, blank contamination did not result in the qualification of data.

Trip Blanks. Trip blanks are intended to identify contamination from exposure to atmospheric contaminants that may occur during various stages of the sampling process including: shipment of bottles on-site, storage of bottles on-site, collection of samples on-site, storage of samples on-site, shipment of samples to the laboratory, and storage of samples in the laboratory. For each VOC sampling sequence, a trip blank was documented and placed in the cooler (at 4±2°C) in which TCL VOCs sample fractions were stored. Trip blanks were analyzed for TCL VOCs at the CRQL, and were associated with every aqueous VOC sample fraction. Chain-of-custody records were reviewed to ensure completeness.

Based on a review of the trip blanks, acetone should be considered non-detect in sample L1GW64. Methylene chloride should be considered non-detect in the following samples: L3GW63, L4GW63, and L5GW63. No other qualifications are necessary.

3.7.5.5 Completeness and Representativeness

Sampling completeness of the CHAAP RI/FS was assessed through the evaluation of the total number of samples proposed in the work plan versus the actual number of samples collected and analyzed. This criterion expresses the degree of accuracy and precision to which sample data represents the population. The criterion for completeness specified in the USAEC QA Program is 80% or greater. All investigation areas were in compliance with the USAEC criterion for completeness.

Former UST and AST Locations

Ninety-six environmental samples were proposed for collection and analysis in support of these investigation areas. All the samples proposed for this area were collected, resulting in a completeness quotient of 100%.

3.7.6 Data Reporting

Chemical data have been reported in IRDMIS. Qualification of the data as a result of the USAEC validation and review has also been reported in IRDMIS. Data limitations identified during data validation are reported in **Appendix A**. All the analytical data is also presented in **Appendix A**.

A corrective action for select 1996 RI aqueous benzo[a]pyrene analyses has been submitted (see Appendix A). For the following aqueous samples, a laboratory error led to the reporting of benzo[a]pyrene as 0.02 µg/L (incorrect) instead of non-detect at 0.02 µg/L (correct):

L1GW64
L3GW63
L4GW63
SHGW01
SHGW03

SHGW04
L2GW63
L5GW63
SHGW02

As a result, benzo[a]pyrene is reported in the current data in Appendix A as 0.02 µg/L which will be corrected to non-detect.

3.8 DATA MANAGEMENT

Chemical, geotechnical, and map data generated during this EI were input into the USAEC IRDMIS database system as described in the CHAAP Quality Assurance Project Plan (**USAEC, 1994**). The IRDMIS is an integrated system for the collection, validation, storage, retrieval, and presentation of Installation Restoration and Base Closures data. IRDMIS PCTool is a major component of IRDMIS, which provides the ability to enter, chemical, geotechnical, and map data in support of the USAEC Installation Restoration and Base Closure Programs. Each contractor is supplied with the appropriate microcomputer-based software to allow for record entry, error checking, and quality control for chemical, geotechnical and map data into IRDMIS. Records accepted by the local error checking program are then transmitted through a Bulletin Board System (BBS), AT&T Model 3B2 minicomputer, which is centrally located at USAEC's Edgewood, MD facility. Subsequent processing at the central site (duplicate error check) results in an elevation of the accepted records to a higher file "level" and the eventual updating of installation-specific data bases on a Pyramid System.

Analytical data were input directly at the laboratory by ESE Laboratory personnel. Related sampling information necessary to complete the chemical data files was also input at the laboratory, and was derived from the chain-of-custody and field parameter forms that accompanied the samples from CHAAP to ESE Laboratory. The completed chemical files were then run through the IRDMIS record and group check procedures. Any errors were corrected by ICF KE and ESE, and new versions of the transfer files were generated.

Geotechnical and map file data were input using the IRDMIS PC Tool software programs provided by the USAEC. All data were run through the IRDMIS record and group check procedures. All discrepancies were corrected, and new versions of transfer files were generated.

All transfer files were then transmitted by modem to Potomac Research Inc. (PRI) who functions as the IRDMIS data base management contractor for the USAEC. These data were then checked for compliance with IRDMIS formats, and were again run through record and group check procedures. Following the correction of errors or qualification of data by the USAEC Chemist, the files were then input into the IRDMIS Pyramid system.

4.0 AST/UST INVESTIGATION RESULTS

The following section describes the results of the AST/UST investigation conducted at CHAAP. Aboveground storage tanks (ASTs) and USTs were investigated at the load lines (LAP area), the Administration and Base Housing Area, the Shop Area, the Dunnage Area, Building F-3, and Building TD-2 during the 1993 SCD and the 1995 RI field efforts. Soil borings and monitoring wells were completed immediately downgradient from ASTs and at the site of former USTs[1]. **Exhibit 4-1** summarizes the investigation program conducted at these sites.

Contaminants specifically targeted by this UST/AST Report are total petroleum hydrocarbons (TPH), benzene, ethyl benzene, toluene, and xylene (BTEX). Soil sample results were compared to NDEQ soil cleanup guidance values derived from the NDEQ Soil Cleanup Level Scoring Matrix **(NDEQ, 1994)**. The matrix assigns points to a potential clean up site based on several factors including 1) Distance of a tank to the nearest water well, 2) Depth to ground water, 3) Predominant sediment type, 4) Type of contaminant, and 5) Distance to nearest subsurface structure. The cumulative score of the site determines the soil cleanup level to be achieved. Nebraska Department of Environmental Quality guidance values were calculated using this method on a site by site basis. **Exhibit 4-2** and **4-3** displays the NDEQ Soil Cleanup Level Scoring Matrix and the derived site by site calculations. It should be noted that for TPH, only concentrations that exceeded NDEQ calculated soil cleanup criteria are discussed in the following sections. All TPH detections are presented in exhibit data tables. All BTEX detections are discussed in the following sections, because these compounds drive whether or not remedial action is warranted. Compounds detected in soil samples associated with USTs and ASTs other than TPH and BTEX were addressed in the 1996 RI.

Groundwater sample results (petroleum distillates[2] and BTEX) were compared to published NDEQ groundwater cleanup guidance values and Federal MCLs (see **Exhibit 3-2**). Other compounds detected in groundwater samples associated with UST/AST monitoring wells were addressed in the 1996 RI.

4.1 LOAD, ASSEMBLE, AND PACK FACILITIES ASTS AND FORMER USTS

The LAP facilities constitute the major set of buildings and were the center of operations at CHAAP during munitions production years. The LAP facilities are composed of five sets of buildings designated from east to west as Load Lines 1, 2, 3, 4, and 5. This section includes a general discussion of the physical characteristics, history, and description of load line buildings and operations as well as a description of the sampling program implemented to investigate the LAP area ASTs and USTs as well as the results of that program.

Each of the primary load lines (Load Lines 1 to 4) covers approximately 1/2 of a square mile and is enclosed by a chain-link fence that runs along the perimeter of the production area. An exception is Load Line 5 which only covers approximately 1/4 of a square mile. The area surrounding the load line buildings that is within the perimeter fences are vegetated with grasses. Outside the fenced areas the majority of the land surface is cultivated. Small areas of dense vegetation and mature trees are present east of Load Line 4 and southeast of Load Line 2. Topographic relief varies approximately 16 ft over the entire LAP facility area. Elevation is highest at the western edge of Load Line 4 and decreases to the east-northeast. Soils in the LAP facilities are silty to sandy loams, becoming more sandy to the east. Surface silts and clay range from 1 - 13 ft in thickness, becoming thinner to the east. The silt and clay is underlain by 50 - 60 ft of sand and gravel of the Grand Island Formation (Alluvial Aquifer).

No perennial surface-water bodies exist within the LAP facilities area. Surface water run-off is drained by a network of man-made ditches that eventually feed into Silver Creek to the north. The depth to water table has ranged between 6 and 20 ft below ground surface (bgs) during the past 10 years. Groundwater flow in the Alluvial Aquifer is to the east-northeast.

---

[1] Monitoring wells were installed at the same location as the soil borings for all former UST sites investigated.
[2] The term Petroleum Distillates is used by USAEC for TPH in water. This term is synonymous with TPH and all samples were analyzed by USEPA SW-846 M9073: GC.

4.1.1 Load Line 1

One former 550 gallon diesel UST site and two empty 30,000 gallon fuel oil ASTs located on the southwest side of Load Line 1 were investigated during the 1993 SCD and 1995 RI field efforts. The former UST was removed in 1993 and the 30,000 gallon fuel oil ASTs have been empty since the cessation of facility operations. Two soil borings and one monitoring well were installed to investigate the ASTs. One soil boring/monitoring well was installed to investigate the former UST site. **Exhibit 4-4** displays the location of these sampling points. **Exhibit 4-5** summarizes the investigation program conducted at this site.

Logs of soil borings completed in the vicinity of building 1L-24 show that the lithology consists of clay and silty clay to a depth of approximately 8 ft bgs. Poorly sorted sand underlies this surficial silty clay layer to the total depth of the boring. The water table was encountered at approximately 9 ft bgs. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 mg/kg for BTEX (**See Exhibit 4-3**). Detections of TPH and total BTEX above cleanup levels are presented in **Exhibit 4-6**.

Load Line 1 ASTs: Two soil borings (L1SB09 and L1SB10) and one downgradient monitoring well (L1GW64) were installed adjacent to the pair of empty 30,000 gallon fuel oil ASTs located on the southwest side of Load Line 1. Boring L1SB09 extended to a total depth of 13.5 ft bgs and was sampled from 0-2 ft bgs, 6-8 ft bgs (water table interval), and 11.5-13.5 ft bgs. Boring L1SB10 extended to a total depth of 12 ft bgs and was sampled from 0-2 ft bgs, 5-7 ft bgs and 10-12 ft bgs. Monitoring well L1GW64 was screened from 5-20 ft bgs. Results from soil and groundwater samples are presented in **Exhibits 4-7** and **4-8**, respectively.

Boring L1SB09 contained TPH at 1,720 mg/kg in the 0-2 ft bgs interval and 111 mg/kg in the 6-8 ft bgs interval. Boring L1SB10 contained TPH at 657 mg/kg in the 0-2 ft bgs interval. These values exceed the NDEQ soil cleanup guidance of 100 mg/kg. However, BTEX were not detected in any soil samples or groundwater samples.

Load Line 1 Former UST Site: One monitoring well (T1GW1) and its associated soil boring (T1SB1) were installed at the site of former 550 gallon diesel fuel UST 1L-2, T4. The boring extended to a total depth of 21 ft and was sampled from 5-7 ft bgs and 10-12 ft bgs (water table interval). Total petroleum hydrocarbons were below the NDEQ soil cleanup guidance. The monitoring well was screened from 5.5-20.5 ft bgs. Monitoring well T1GW1 contained toluene at 0.719 µg/L which is far below the Federal MCL of 1,000 µg/L.

4.1.2 Load Line 2

Two former 550 gallon diesel UST site and a pair of empty 30,000 gallon fuel oil ASTs located on the southwest side of Load Line 2 were investigated during the 1993 SCD and 1995 RI field efforts. The former USTs were removed in 1993 and the 30,000 gallon fuel oil ASTs have been empty since the cessation of facility operations. One surface soil sample, four borings and one monitoring well were completed to investigate the pair of empty ASTs. Two soil boring and two monitoring wells were completed to investigate the former UST site. **Exhibit 4-9** displays the location of these sampling points. **Exhibit 4-5** summarizes the investigation program conducted at this site.

Logs of soil borings completed in the vicinity of building 2L-24 show that the lithology consists of clay and silty clay to a depth of approximately 11 ft bgs. Moderately sorted sand underlies this surficial silty clay layer to the total depth of the boring. Deeper borings in the area indicate that this sandy layer extends downward to a depth of 40-50 ft bgs. The water table was encountered at approximately 10.5 ft bgs. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 ppm for BTEX (**See Exhibit 4-3**). Detections of TPH and total BTEX above cleanup levels are presented in **Exhibit 4-10**.

Load Line 2 ASTs: One surface soil sample (LL02-18), four soil borings (L2SB09, LL2SB001, LL2SB002, and L2SB10), and one downgradient monitoring well (L2GW63) were completed adjacent to the pair of empty 30,000 gallon fuel oil ASTs at Load Line 2. Monitoring well L2GW63 was screened from

5.5 to 20.5 ft bgs and straddled the water table. **Exhibits 4-7** and **4-8** present TPH and BTEX concentrations in soil and groundwater samples collected from Load Line 2 ASTs.

Aromatic compounds BTEX were not detected above the NDEQ soil cleanup guidance. Surface soil sample LL02-18 contained TPH at 222.0 mg/kg, exceeding NDEQ guidance of 200 mg/kg. Groundwater samples collected from L2GW63 did not contain any detections of petroleum distillates or BTEX.

Load Line 2 Former UST Sites: Soil borings and monitoring wells were completed at the site of two former diesel USTs in the southwest corner of Load Line 2, adjacent to building 2L-24. The borings were sampled every five feet and at the water table interface (10-12 ft bgs). Soil samples were analyzed for TPH and BTEX. Monitoring wells were constructed with 15 ft screens which straddled the water table. Groundwater samples were also analyzed for TPH and BTEX.

Soil boring T2SB1 (tank 2L-24, T4) contained toluene at 0.0397 mg/kg, far below the USEPA Region III Residential RBC. No other compounds were detected in these samples.

Groundwater sample T2GW1 (tank 2L024, T4) contained ethylbenzene (30.8 µg/L), toluene (2.83 µg/L) and xylene (67.1 µg/L), none of which exceeded Federal MCLs or NDEQ groundwater quality standards. Petroleum distillates were detected at 1,140 µg/L. Groundwater sample T3GW1 (tank 2L-24, T5) contained toluene at 1.29 µg/L, which is far below the Federal MCL and NDEQ groundwater quality standard. Petroleum distillates were detected at 1,100 µg/L. No other compounds were detected in these samples.

4.1.3 Load Line 3

One former 550 gallon diesel fuel UST site and a pair of empty 30,000 gallon fuel oil ASTs located on the southwest side of Load Line 3 were investigated during the 1993 SCD and 1995 RI field efforts. The former UST was removed in 1993 and the 30,000 gallon fuel oil ASTs have been empty since the cessation of facility operations. One surface soil sample, four borings and one monitoring well were completed to investigate the pair of empty ASTs. One soil boring and one monitoring well was completed to investigate the former UST site. **Exhibit 4-11** displays the location of these sampling points. **Exhibit 4-5** summarizes the investigation program conducted at this site.

Logs of soil borings completed in the vicinity of building 3L-24 indicate that the lithology consists of silty clay to a depth of approximately four ft bgs. Moderately well sorted sand underlies this surficial silty clay layer to the total depth of the boring. Deeper borings in the area indicate that this sandy layer extends downward to a depth of 40-50 ft bgs. The water table was encountered at approximately 10 ft bgs. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 ppm for BTEX (**See Exhibit 4-3**). Detections of TPH and total BTEX above cleanup levels are presented in **Exhibit 4-12**.

Load Line 3 ASTs: One crossgradient surface soil sample (LL03-22), four borings (L3SB07, LL3SB001, LL3SB002, and L3SB08), and one downgradient monitoring well (L3GW63) were completed adjacent to the pair of empty 30,000 gallon fuel oil ASTs located on the southwest side of Load Line 2. Monitoring well L3GW63 was screened from 6.5 to 21.5 ft bgs and straddled the water table.

Total petroleum hydrocarbons were detected exceeding NDEQ guidance in the 0-2 ft bgs interval of L3SB001 (6,830 mg/kg), L3SB08 (5,880 mg/kg), L3SB002 (169 mg/kg), and LL03-22 (191 mg/kg). Aromatic compounds BTEX were not detected.

Groundwater sample L3GW63 contained toluene (0.98 µg/L) at a concentration below the Federal MCL and Nebraska Groundwater Quality Standard. Petroleum distillates were detected at 3,770 µg/L.

Load Line 3 Former UST Sites: One monitoring well (T4GW1) and its associated boring (T4SB1) were installed at the site of former 550 gallon diesel UST 3L-24, T4. The boring was sampled every five feet and at the water table interface (10-12 ft bgs). Soil samples were analyzed for TPH and BTEX. The monitoring well was constructed with 15 ft screens which straddled the water table. Groundwater samples were also analyzed for TPH and BTEX. **Exhibits 4-7** and **4-8** display the analytical detections in soil and groundwater above CRLs.

Total petroleum hydrocarbons and BTEX were not detected above the calculated NDEQ soil cleanup guidance of 100 mg/kg. Petroleum distillates and BTEX were not detected in groundwater sample T4GW1.

4.1.4 Load Line 4

Four former 550 gallon diesel fuel UST sites and a pair of empty 30,000 gallon fuel oil ASTs located on the southwest side of Load Line 4 were investigated during the 1993 and 1995 field efforts. The former USTs were removed in 1993 and the 30,000 gallon fuel oil ASTs have been empty since the cessation of facility operations. One surface soil sample, three borings, and one monitoring well were completed to investigate the pair of empty ASTs. Four soil borings and four monitoring wells was completed to investigate the former UST site. **Exhibit 4-13** displays the location of these sampling points. **Exhibit 4-5** summarizes the investigation program conducted at this site.

Logs of soil borings completed in the vicinity of building 4L-24 indicate that the lithology consists of silty clay to a depth of approximately nine ft bgs. Silty sand underlies this surficial silty clay layer to the total depth of the boring. Deeper borings in the area indicate that this sandy layer extends downward to a depth of 40-50 ft bgs. The water table was encountered between 10 and 12 ft bgs. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 ppm for BTEX (**See Exhibit 4-3**). Detections of TPH and total BTEX above cleanup levels are presented in **Exhibit 4-14**.

Load Line 4 ASTs: One crossgradient surface soil sample (LL04-19), two soil borings (L4SB09 and L4SB10), and one downgradient monitoring well (L4GW63) were completed adjacent to the pair of empty 30,000 gallon fuel oil USTs located on the southwest side of Load Line 4. The borings were sampled every five feet. Monitoring well L4GW63 was screened from 6-21 ft bgs and straddled the water table.

Total petroleum hydrocarbons were not detected above the calculated NDEQ soil cleanup guidance of 100 mg/kg. Aromatic compounds (BTEX) were not detected in soil.

Groundwater sample L4GW63 contained toluene (0.91 µg/L). However, the concentration was below the Federal MCLs and Nebraska Groundwater Quality Standards.

Load Line 4 Former UST Sites: Soil borings (T5SB1, T6SB1, T7SB1, T8SB1) and monitoring wells (T5GW1, T6GW1, T7GW1, T8GW1) were completed at the site of two former 2000 gallon gasoline USTs (4L-1 T1 and 4L-1 T2) east of building 4L-1 and two former 550 gallon diesel USTs (4L-24 T4 and 4L-24 T5) in the southwest corner of Load Line 2, adjacent to building 4L-24. The borings were sampled every five feet and at the water table interface (10-12 ft bgs). Monitoring wells were constructed with 15 ft screens which straddled the water table. **Exhibits 4-7** and **4-8** display all analytical detects above CRLs.

TPH was detected in T8SB1 (tank 4L-24, T5) at 1,890 mg/kg. With the exception of T8SB1, none of these detections exceeded the calculated NDEQ soil cleanup guidance of 100 mg/kg.

Groundwater sample T5GW1 (tank 4L-1, T1) contained toluene at 1.01 µg/L which is below the Federal MCL (1,000 µg/L) and Nebraska Groundwater Quality Standard of 1,000 µg/L. Sample T8GW1 (tank 4L-24, T5) contained ethylbenzene (1.26 µg/L), xylenes (7.69 µg/L), toluene (1.21 µg/L) at concentrations below Federal MCLs and Nebraska Groundwater Quality Standards. Petroleum distillates were detected at a concentration of 9,420 µg/L in sample T5GW1. No other compounds were detected in groundwater.

4.1.5 Load Line 5

One empty 30,000 gallon fuel oil AST located north of building B-3 on the north side of Load Line 5 was investigated during the 1995 field effort. The 30,000 gallon fuel oil AST has been empty since the cessation of facility operations. One soil boring and one monitoring well were completed to investigate the empty AST. **Exhibit 4-15** displays the location of these sampling points. **Exhibit 4-5** summarizes the investigation program conducted at this site.

Soil borings in the vicinity of Load Line 5 indicate the lithology consists of silty clay to a depth of 14 ft. The silty clay layer is underlain by silty fine sand to the total depth of the boring. The water table was encountered at 12 ft bgs. There are no water wells within 500 ft and no underground structures within 25

ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 ppm for BTEX (**See Exhibit 4-3**). Detections of TPH and total BTEX above cleanup levels are presented in **Exhibit 4-16.**

Load Line 5 ASTs: One soil boring (L5SB06) and one monitoring well (L5GW63) were completed at the site of the empty 30,000 gallon AST located north of building B-3. The boring extended to a depth of 14 ft bgs and was sampled from 0-2, 10-12, and 12-14 ft bgs. The monitoring well was screened from 6-21 ft bgs. **Exhibits 4-7** and **4-8** present detection in soil and groundwater above CRLs.

None of the TPH detections exceeded the calculated NDEQ soil cleanup guidance. Aromatic compounds, BTEX, were not detected in soil. Groundwater sample L5GW63 contained toluene at 0.79 µg/L. However, the concentration did not exceed the Federal MCL or the Nebraska Groundwater Quality Standards.

4.2 ADMINISTRATION AND BASE HOUSING AREA

The Administration and Base Housing Area (ABHA) is located in the southeast corner of the installation. The area was used as an administration complex and a residence complex as well as housing a hospital, cafeteria, and USAF satellite tracking station. The area encompasses approximately one square mile and is bounded by the facility boundary to the south and the Nitrate Area to the north. The topography in the area is relatively flat, sloping no more than ten feet across the site. Because of minimal contamination at the ABHA, this area of concern was designated as Operable Unit Two in the 1996 RI. A Record of Decision for no further action was signed in 1997.

Boring logs from this area show that the lithology consists of silt to sandy silt to a depth of approximately four feet underlain by silty sand and sand to the total depth of the borings. Deeper borings in the Nitrate Area indicated that the area is underlain by sand to a depth of 40-50 ft bgs. The water table was encountered between 11 and 15 feet. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 ppm for BTEX (**See Exhibit 4-3**). Detections of TPH and total BTEX above cleanup levels are presented in **Exhibit 4-18**.

ABHA USTs: Soil borings and monitoring wells were completed at the site of eight former USTs in the Administration Area and eight former USTs in the Base Housing Area (one of which was located at tank 172-A, T1 adjacent to the Commander's Residence east of the facility). **Exhibit 4-16** and **4-17** display the locations of these sampling points. The borings were sampled every five feet and at the water table interface. Soil samples were analyzed for TPH and BTEX. Monitoring wells were constructed with 15 ft screens which straddled the water table. **Exhibit 4-5** summarizes the investigation program conducted at the ABHA.

Soil boring T22SB1 (tank 172-A, T1) located at the Commander's Residence contained TPH concentrations of 808 mg/kg in the 8-10 ft bgs interval and 1,400 mg/kg in the 10-12 ft bgs interval (water table), both of which exceed the calculated NDEQ soil cleanup guidance.

Four groundwater samples, T10GW1 (tank A-4, T1), T11GW1 (tank A-4, T2), T14GW1 (tank A-13, T1), and T16GW1 (tank USAF-1, T1) from the Administration Area and five groundwater samples, T17GW1 (tank ER-1, T1), T18GW1 (tank ER-5, T1), T22GW1 (tank 172-A, T1), T29GW1 (tank ER-12, T1), and T30GW1 (tank ER-14, T1) from the Base Housing Area contained toluene concentrations ranging from 0.777-2.96 µg/L, none of which exceeded Federal MCLs or the Nebraska Groundwater Quality Standards. Petroleum distillates, benzene, ethyl benzene, and xylene were not detected in groundwater. **Exhibits 4-7** and **4-8** present soil and groundwater detections above CRLs.

4.3 SHOP AREA ASTS AND FORMER USTS

The Shop Area, located in the east-central area of the facility, immediately south of Load Line 1, covers an area of about 1,500 x 2,000 ft and includes 28 buildings and sheds. The Shop Area consists of the installation laundry and a settling basin for laundry wastewater; maintenance facilities for vehicles, equipment and other operations; rail loading and unloading area; open storage areas; and underground and aboveground storage tanks. The area is currently used for miscellaneous storage and as the support area for environmental investigations.

Three former USTs and five empty ASTs located in the Shop Area were investigated during the 1993 SCD and the 1995 field effort. The USTs were removed during 1993 and the ASTs have been empty since the cessation of facility operations. One surface soil sample, five soil borings, and six monitoring wells were completed to investigate the ASTs. Three soil boring/monitoring well pairs were completed to investigate the USTs. **Exhibit 4-19** displays the location of these sampling points. **Exhibit 4-5** summarizes the investigation program conducted at the Shop Area.

Logs of soil borings completed in the Shop Area show that the lithology consists of silt to approximately four ft bgs. This layer of silt is underlain by sand to the total depth of the boring. The water table was encountered at approximately six ft bgs. There are no subsurface structures within 25 ft of any of these locations. Well T28GW1 is located adjacent to water well S-003 (the USAEC designated water source), but this well is set in a deeper aquifer hydraulically unconnected to the Alluvial Aquifer. According to NDEQ guidance, these conditions warrant a soil cleanup level of 100 ppm (mg/kg) for TPH and 100 ppm (mg/kg) for BTEX (**See Exhibit 4-3**). Detections of TPH and total BTEX above cleanup levels are presented in **Exhibit 4-20**.

Shop Area ASTs: Five ASTs were investigated in the Shop Area during the 1993 and 1995 field efforts. The tanks, which are currently empty, had differing capacities and contained varying materials. Four of the tanks, S12 (577,500-gallon diesel with spill containment berm), S-32 (10,000-gallon road tar), S-33 (12,000-gallon road tar), and S-35 (12,000-gallon road tar) are located on the eastern end of the Shop Area, east of Building S-13. The fifth tank, S-6 (1,000-gallon waste oil) is located adjacent to the eastern side of Building S-6.

One surface soil sample, SHOPSR015 (tank S-6); five soil borings, SHOPSB013 and SHSB17 (tank S-12), SHOPSB010 (tank S-32), SHOPSB011 (tank S-34), SHSB15 (tank 3-35), and SHOPSB006 (tank S-6); and six monitoring wells, G0069 and SHGW04 (tank S-6), SHGW02 (tank S-32), SHGW03 (tank S-34), G0053 (tank S-35), and G0050 (tank S-6) were completed adjacent to Shop Area ASTs. **Exhibit 4-7** presents TPH and BTEX detections in soil. **Exhibit 4-8** presents petroleum distillates and BTEX detections in groundwater.

The following discussion summarizes TPH above the NDEQ cleanup guidance and all BTEX detected in soil and groundwater in the vicinity of each Shop Area AST and UST.

S-12 (577,500-gallon No. 2 Diesel AST)

One upgradient boring, SHSB16, and two downgradient borings, SHSB17 and SHOPSB013, were completed in the vicinity of the 577,500-gallon diesel tank.

Benzene was detected in one of the two monitoring wells downgradient of the 577,500-gallon diesel tank. Groundwater collected from SHGW04 contained benzene (0.99 µg/L). However, this concentration is below the Federal MCL of 5 µg/L.

S-32, S-34, and S-35 (Road Oil ASTs)

Four downgradient borings, SHSB15, SHSB16, SHOPSB010, and SHOPSB011, were completed in the vicinity of the three road oil tanks. TPH was detected in soil samples collected from SHSB15 at concentrations of 598 mg/kg at the 0-2 ft depth interval. SHSB15 soil samples contained TPH (22.8 mg/kg) in the 0-2 ft depth interval only. SHOPSB010 soil samples contained TPH concentrations of 154 and 583 mg/kg at 2-4 and 10-12 ft bgs, respectively. The highest TPH concentrations in soil were detected from SHOPSB011 at 2-4 ft bgs (7,640 mg/kg), 5-7 ft bgs (3,410 mg/kg), and 10-12 ft bgs (5,310 mg/kg). Only the near surface soils from SHSB15 and SHOPSB010, and the three soil samples collected from SHOPSB011 contained TPH concentrations above the NDEQ soil cleanup guidance value of 100 mg/kg. Low levels of toluene, ethylbenzene, and xylenes were detected in several soil samples collected from SHSB15, SHOPSB010, and SHOPSB011, but at concentrations well below their respective USEPA Region III Residential RBCs.

Contaminants of concern were detected in both of the monitoring wells downgradient of the three road oil ASTs, SHGW02, and SHGW03. The following compounds were detected in groundwater collected from SHGW03 including benzene (1.9 µg/L), toluene (0.98 µg/L), ethylbenzene (4.8 µg/L), and

xylenes (23 µg/L). None of the concentrations were above Federal MCLs or Nebraska Groundwater Quality Standards.

S-6 (1,000-gallon Waste Oil AST)

One surface soil sample, SHOPSR015, and three subsurface soil samples from one soil boring, SHOPSB06, were collected in the vicinity of the 1,000-gallon waste oil AST. Toluene (0.71 mg/kg) was detected in the 2-4 ft bgs interval of boring SHOPSB06. The toluene concentration is well below the USEPA Region III Residential RBC. The TPH concentration is below the calculated NDEQ soil cleanup guidance of 100 mg/kg. No groundwater samples were collected in this location.

S-14 (1,000-gallon Solvent UST)

One soil boring/monitoring well (T23GW1/T23GW1) was drilled in the location of the former 1,000-gallon solvent UST. Total petroleum hydrocarbons were detected, however, the concentrations were below the NDEQ soil cleanup guidance value of 100 mg/kg. No BTEX were detected in the subsurface soil.

Toluene (1.15 µg/L), ethylbenzene (0.86 µg/L), and xylenes (6.14 µg/L) were detected in groundwater from T23GW1 at concentrations below the Federal MCLs and Nebraska Groundwater Quality Standards.

S-40 (34,000-gallon Gasoline UST)

One soil boring/monitoring well (T24SB1/T24GW1) was drilled in the location of the former 34,000-gallon gasoline UST. Total petroleum hydrocarbons were detected in soil at 254 mg/kg from the 5-7 ft depth interval which is above the calculated NDEQ soil cleanup guidance for TPH of 100 mg/kg. No petroleum distillates or BTEX were detected from groundwater samples collected from T24GW1.

SPHA-3 (2,000-gallon Gasoline UST)

One soil boring/monitoring well (T28SB1/T28GW1) was drilled in the location of the former 2,000-gallon gasoline UST. Total petroleum hydrocarbons were not detected in soil at this location. Groundwater samples collected from T28GW1 did not contain concentrations of BTEX and petroleum distillates.

4.4 OTHER AREA FORMER UST LOCATIONS

This section discusses former UST locations at the Dunnage Area, at Building F-3, and at Building TD-2. These areas, collectively grouped as Miscellaneous Storage Areas, were designated as part of Operable Unit Two during the 1996 RI. A ROD for no further action was signed in 1997.

4.4.1 Dunnage Area Former UST Site

The Dunnage Area is located south east of Load Line 3 north of Sixth Ave. Boring logs from this area show that the lithology consists of silty clay to a depth of 23 ft bgs. Well sorted sand underlies this silty clay layer to the total depth of the boring. The water table was encountered at 7.5 ft bgs. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm (mg/kg) for TPH and 100 ppm (mg/kg) for BTEX (see **Exhibit 4-3**).

Soil boring T25SB1 and associated monitoring well T25GW1 were located at the site of former 4,000 gallon heating oil UST (tank D-1, T1) which was removed in 1993. Boring T25SB1 was sampled at 5-7 and 10-12 ft bgs for BTEX and TPH. Monitoring well T25GW1 was screened across the water table from 5-20 ft bgs. Groundwater samples were analyzed for BTEX and TPH. **Exhibit 4-5** summarizes the investigation program conducted at the site. **Exhibit 4-7** and **4-8** present all detections of TPH and BTEX.

Soil boring T25SB1 contained a TPH concentration of 104 mg/kg in the 5-7 ft bgs interval. This concentration slightly exceeds the calculated NDEQ soil cleanup value of 100 mg/kg. Groundwater sample T25GW1 contained toluene at 0.706 µg/L. However, this detection was qualified as non-detect based on the toluene concentration of 3.1 µg/L in the associated rinse blank RBGW101.

4.4.2 Building F-3 Former UST Site

Building F-3 is located south of Load Line 3 off of Sixth Ave (see **Exhibit 4-21**). Boring logs from this area show that the lithology consists of silty clay to a depth of 23 ft bgs. Well sorted sand underlies this silty clay layer to the total depth of the boring. The water table was encountered at 7.5 ft bgs. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 ppm for BTEX (**See Exhibit 4-3**). Predominant groundwater flow is to the east-northeast.

Soil boring T26SB1 and associated monitoring well T26GW1 were located at the site of former 5,100 gallon heating oil UST (tank F-3, T1) which was removed in 1993. Boring T26SB1 was sampled at 8-10 and 14-16 ft bgs for BTEX and TPH. Monitoring well T26GW1 was screened across the water table from 4.3-19.3 ft bgs. **Exhibit 4-5** summarizes the investigation program conducted at the site. No TPH or BTEX compounds were detected from soil boring T26SB1 or monitoring well T26GW1.

4.4.3 Building TD-2 Former USTs

Building TD-2 is located south of Load Line 1 off of Sixth Ave. Boring logs from this area show that the lithology consists of silty clay to a depth of 5 ft bgs. Well sorted sand underlies this silty clay layer to the total depth of the boring. The water table was encountered at 7.5 ft bgs. There are no water wells within 500 ft and no underground structures within 25 ft. According to NDEQ guidance, these conditions warrant a cleanup level of 100 ppm for TPH and 100 ppm for BTEX (**See Exhibit 4-3**).

Soil boring T27SB1 and associated monitoring well T27GW1 were located at the site of former 5,100 gallon heating oil UST F-3, T1 which was removed in 1993. Boring T27SB1 was sampled at 8-10 and 14-16 ft bgs for BTEX and TPH. Monitoring well T27GW1 was screened across the water table from 6-21 ft bgs. Groundwater samples were analyzed for BTEX and TPH. **Exhibit 4-5** summarizes the investigation program conducted at the site and **Exhibits 4-7** and **4-8** display all analytical detects above CRLs.

No BTEX or TPH compounds were detected in soil boring T27SB1. Groundwater sample T27GW1 contained toluene at 1.16 µg/L, which is below the Federal MCL and the Nebraska Groundwater Quality Standard. It should be pointed out that the toluene concentration should be considered non-detect due to the presence of toluene at 3.1 µg/L in rinse blank RBGW101. No other compounds were detected in groundwater.

[1] Soil borings were located in the center of the former UST locations. Soil samples were collected every 5 feet (from 0-2', 5-7', etc.), at the water table, and at the screened interval of the subsequent monitoring well. The soil samples were screened visually and with a PID for evidence of contamination. The water table interface soil sample and the soil sample with the highest PID reading were analyzed for TPH and BTEX. Because UST S-14, T1 may have contained solvents, associated samples were also analyzed for TCL VOCs. The samples collected from the three former gasoline tanks (4L1-T2, A12-T1, and SHPA3-T1) were analyzed for Lead.

[2] The soil borings were completed as 4-in. diameter monitoring wells, screened across the water table and were sampled for TPH and BTEX. Because UST S-14, T1 may have contained solvents, these samples were also analyzed for TCL VOCs. Lead was analyzed for from the samples from the three former gasoline tanks (4L1-T2, A12-T1, and SHPA3-T1).

[3] The removal location in question was addressed by a "No-Further-Action" letter from NDEQ.

[4]TPH was not detected at these tank locations during UST removal sampling. However, due to the proximity to tank locations where TPH was detected, these tank locations were included as areas requiring further investigation by NDEQ.

5.0 CONCLUSIONS

Aboveground Storage Tanks and USTs were investigated at the Load Lines; The Administration and Base Housing Area; miscellaneous storage areas (i.e., Dunnage Area, Building F-3, and Building TD-2); and the Shop Area. Soil borings were completed immediately downgradient of the ASTs and at the sites of former USTs to determine the lateral and vertical extent of soil contamination. **Exhibit 5-1** presents all detections of BTEX and TPH above NDEQ soil cleanup guidance. No Federal MCLs were exceeded for BTEX in any groundwater samples collected from monitoring wells associated with USTs or ASTs at CHAAP. Provided below are summaries of soil and groundwater contamination as a result of UST and AST operations:

Operable Unit One:

Load Line 1: Total Petroleum Hydrocarbons were detected at levels that exceeded the NDEQ cleanup guidance level of 200 µg/g in soil samples collected in the vicinity of AST 1L-AST which contained No. 6 Fuel Oil. However, BTEX was not detected in soil or groundwater.

Load Line 2: At Load Line 2, TPH exceeded the NDEQ cleanup guidance level of 200 µg/g at UST 2L-24-T4 which contained No.#6 Fuel Oil. The total BTEX concentration detected was 0.0397 µg/g which is far below the NDEQ cleanup guidance level of 1,000 µg/g.

Load Line 3: At Load Line 3, TPH exceeded the NDEQ cleanup guidance level of 200 µg/g in samples collected in the vicinity of AST 3L-AST which contained No#6 Fuel Oil. The concentrations were 5,880 µg/g and 6,830 µg/g. However, BTEX was not detected in soil or groundwater.

Load Line 4: At Load Line 4, TPH exceeded the NDEQ cleanup guidance level of 100 µg/g in samples collected in the vicinity of UST 4L-24-T4 which contained Diesel. The total BTEX concentration was 10.16 µg/g which is far below the NDEQ cleanup guidance level of 100 µg/g. Benzene was below the NDEQ cleanup guidance level of 0.5 µg/g.

Operable Unit Two:

Dunnage Area: Total petroleum hydrocarbons (104 µg/g) slightly exceeded the NDEQ cleanup guidance level of 100 µg/g from a sample collected from UST D-1-T1 which contained heating oil. However, BTEX was not detected.

Administration Area and Base Housing: Two samples collected from the vicinity of the ABHA contained concentrations (808 and 1,400 µg/g) that exceeded the NDEQ cleanup guidance level of 100 µg/g. However, BTEX was not detected.

Operable Unit Three:

Shop Area: A sample collected from the vicinity of UST S-40-T1 which contained gasoline showed a TPH detection of 254 µg/g which exceeds the NDEQ cleanup guidance level of 100 µg/g. However, BTEX was not detected. Samples collected from five ASTs at the Shop Area have total BTEX detections, however the concentrations are far below NDEQ soil cleanup guidance. Benzene was not detected in any of the samples. Total petroleum hydrocarbons exceeded NDEQ cleanup guidance levels from samples collected associated with AST S-40-T1, AST S-13-S-32, AST S-13-S-34, S-13-S-35, and S-6-S-6.

As shown above, no detections associated with USTs and ASTs at CHAAP contain concentrations that exceed site-specific NDEQ soil cleanup guidance for Benzene or Total BTEX. Only TPH exceed NDEQ soil guidance levels. Furthermore, groundwater was not impacted by USTs or ASTs used for petroleum product storage at CHAAP. Based on these results, no further remedial action is recommended for USTs and ASTs at CHAAP.

Exhibit 5-1: Summary of Contamination Related to UST/AST Operations

UST	UST/AST	Boring ID	Depth	Type of Fuel	Removed	Distance to Nearest Well	Depth to Groundwater	Predominant Sed. APPENDIX A

Analytical Data

DATA VALIDATION MEMORANDUM
FOR 1995 RI SAMPLES ANALYZED BY USEPA SW-846 METHOD 8310

◆ ICF KAISER

DATA EVALUATION

Case #	N/A	Site	Cornhusker	Matrix: Soil	193
Date	23 Feb. 96	Lab	ES&E	Water	43
Reviewer	R. Finke				

Validation was performed on eighty two (82) soil samples analyzed for Polynuclear Aromatic Hydrocarbon (PAH) determinations by USEPA SW-846 method 8310/3540D/3540A-D and twenty four (24) aqueous samples for PAH determinations analyzed by USEPA SW-846 method 8310/3510D . The validation of the data was performed in accordance with the methodologies specified, the National Functional Guidelines and USEPA data validation Standard Operating Procedures, where applicable. Quality control items reviewed included holding times, initial and continuing calibration criteria, retention time window criteria, calculations, blank data, spike data, surrogate and duplicate data. The following are the samples reviewed and the action(s) taken.

Soil Samples:

BGSB01,02	L1SB09,10	NISB10-12	PRWL04,05
BDSE02,03	L2SB09,10	NISL31-46	PRST07-10
DSO202	L3SB07,08	PRSB01,02	SHSB20
GVSL31-39	L4SB09,10	PRSB04-10	SHSB15-17
GVSL41,42	L5SB06	PRSB13-19	SBSL02,03
GVSB04-06	NFSB03,06,07,08	PRSB21,22	SPSB01-03
			SHST01

Aqueous Samples:

GVGW01,02	L5GW63	SPGW01
L1GW64	NIGW02,03	RBGW101,103
L2GW63	PRGW01-05	RBS102,104
L3GW63	SFGW01,02	
L4GW63	SHGW02,04	

Surrogate and Spike Recoveries:

Several sample batches possessed surrogate and sample matrix spike recoveries outside the established recovery window criteria. The reason for the outlying recoveries appear to be sample matrix dependant and not due to laboratory performance, therefore, no qualification of the data was deemed necessary.

No other problems or deficiencies have been discovered with this case.

LABORATORY CORRECTIVE ACTION REPORT FOR BENZO (A) PYRENE ("BAPYR") IN WATER 1995 RI SAMPLES

Environmental
Science &
Engineering, Inc.

April 9, 1996

Mr. Michael Kipp
ICF Kaiser Engineers, Inc.
9300 Lee Highway
Fairfax, VA 22031

Re: Corrective Action Report

Dear Mr. Kipp:

Enclosed is a corrective action report for the Cornhusker AAP project. This report pertains to results of analysis for PAHs (Method 8310) reported during 1995. Several sample results needed to be revised due to a rounding error in the ESE Denver Laboratory data management system.

ESE apologizes for this instance and regrets any inconveniences ICF may have suffered as a result.

Thank you for giving ESE this opportunity to be of service.

Sincerely,

ENVIRONMENTAL SCIENCE & ENGINEERING, INC.

Charles E. Fiore

April 4, 1996

Please find enclosed the TRN files for the following lots that are being resubmitted for corrections and were analyzed by the following non-certified USAEC method:

LOT	METHOD CODE
KJL, KJB, KJH, KJM	8310

All four lots in this resubmission have had the found value for analyte 'BAPYR' changed from a hit to a non-detect. The decimal place setting for this analyte in our LIMS system caused a rounding discrepancy that resulted in a incorrect positive result to be reported in the TRN file. Below is a listing of which samples were changed:

Lot KJL (8310) - SAMPLE NUMBER: 001 for analyte 'BAPYR'.

Lot KJB (8310) - SAMPLE NUMBERS: 001, 002, 003, 004 and 005 for analyte 'BAPYR'.

Lot KJH (8310) - SAMPLE NUMBERS: 001, 002, 003, 004, 005, 006 and 007 for analyte 'BAPYR'.

Lot KJM (8310) - SAMPLE NUMBERS: 001, 002, 003, 004 and 005 for analyte 'BAPYR'.

Please feel free to call if you have any questions.

- Jeff Mott

Groundwater Samples Affected by Benzo[a]pyrene Corrective Action

A-2, T1

2L-24, T5 (285 gallon): The tank appeared in poor condition and showed signs of severe corrosion. The tank had several small holes due to the thin walls in the tank. Some tank contents had leaked into the surrounding excavation area. Excavation removed the soil contaminated by the leaking tank.

3L-24, T4 (560 gallon): The tank appeared in good condition and showed signs of slight corrosion. No leaking of tank contents into the surrounding excavation areas was evident.

3L-24, T5 (560 gallon): The tank appeared in good condition and showed no signs of corrosion. No leaking of tank contents into the surrounding excavation areas was evident.

4L-1, T1 & 4L-1, T2 (2000 gallon each): The tanks appeared in good condition and showed no signs of corrosion. The tanks were approximately within the same excavation area. No leaking of tank contents into the surrounding excavation areas was evident.

4L-24, T4 (560 gallon): The tank appeared in good condition and showed no signs of corrosion. No leaking of tank contents into the surrounding excavation was evident.

4L-24, T5 (285 gallon): The tank appeared in fair condition and showed signs of moderate corrosion. No leaking of tank contents into the surrounding excavation was evident.

S39, T2 (250 gallon): The tank appeared in good condition and showed no signs of corrosion. No leaking of tank contents into the surrounding excavation was evident.

A2, T1 (150 gallon): The tank appeared in fair condition and showed signs of corrosion indicative of tanks of tins size. No leaking of tank contents into the surrounding excavation was evident.

Cornhusker AAP
Grand Island, NE
Contract No. DACA45-93-C-0039

Facility ID #2337

Tank Use

These tanks were located at the Cornhusker AAP in Grand Island, NE. The site was used for ammunition manufacturing until the 1950's. Underground storage tanks removed under this project were used as a fuel source for generators and/or motors.

Excavation

The U.S. Army Corps of Engineers directed Tony's Cement Works to excavate soil that was visibly contaminated (i.e. discolored). Approximately three to six feet on all sides of the tanks were excavated.

Backfill

Backfill of the excavation was conducted under the direction of the Army Corps of Engineers and in accordance with section 02070 of the contract specifications.

Ground water

No ground water was encountered during excavation of the tanks.

Tanks

S14, T1 (1000 gallon): The tank appeared in good condition and showed only slight signs of corrosion. No leaking of tank contents into the surrounding excavation areas was evident.

WH-3, SPHA3 (45 gallon): The tank (drum) appeared in good condition and showed signs of corrosion typical of tanks of this size. No leaking of tank contents into the surrounding excavation areas was evident.

1L-24, T4 (285 gallon): The tank appeared in poor condition and showed signs of severe corrosion. Tanks of this size typically show moderate to severe corrosion due to the thin walls of the tank. The tank had numerous small holes in the tank due to rust and corrosion. Tank contents had leaked into the surrounding excavation area. Excavation removed the soil contaminated by the leaking tank.

2L-24, T4 (285 gallon): The tank appeared in fair condition and showed signs of slight corrosion. No leaking of tank contents into the surrounding excavation areas was evident.

CERTIFIED

RE: Petroleum release.
Facility ID Number: 2337 UG# 082793-NM-1335
Facility location: SITE 2L-24, GRAND ISLAND

Dear TOM JAMIESON:

The Department has received the site assessment report for the closure of all or part of the underground storage tank system at the above referenced facility. Information in the report indicates that a release of petroleum resulting from the operation of this system has occurred. The purpose of this letter is to inform you, as the owner of the tank system, of your responsibilities in accordance with Neb. Rev. Stat. 81-15, 124 (Supp. 1989) for securing the release, identifying the affected environment, and completion of any remedial action required by this Department.

The Department will require you to perform an investigation and, if necessary, remediation in accordance with Department of Environmental Control Title 118 - Ground Water Quality Standards and Use Classification Appendix A (enclosed). Costs related to the investigation/remediation of this spill may be eligible for reimbursement in accordance with Title 200 - Rules and Regulations for Petroleum Release Remedial Action Fund (enclosed). However, in order to be eligible for reimbursement, work must first receive prior approval by the Department.

Due to the volume of releases of this kind, the Department is currently prioritizing all new spills related to underground storage tank systems. When this site reaches the top of the priority list, a project manager will be assigned, and you or your company will be contacted with requirements to begin an investigation.

During the interim, you may begin an investigation/remediation. However, because it will not be under the direction of the Department, costs incurred will not be eligible for Title 200 reimbursement. You should also be aware that when this site reaches the top of the priority list and a project manager is assigned, the Department may require you to do work in addition to what you have already completed.

If at any time in the future, public safety is threatened by this spill, the State Fire Marshal (402/471-2027) and our office must be notified. Immediate action should be taken to eliminate the problem.

RE: Petroleum release
Facility ID Number: 2337 UG# 082793-NM-1340
Facility location: SITE 3L-24, GRAND ISLAND

Dear TOM JAMIESON:

The Department has received the site assessment report for the closure of all or part of the underground storage tank system at the above referenced facility. Information in the report indicates that a release of petroleum resulting from the operation of this system has occurred. The purpose of this letter is to inform you, as the owner of the tank system, of your responsibilities in accordance with Neb. Rev. Stat. 81-15, 124 (Supp. 1989) for securing the release, identifying the affected environment, and completion of any remedial action required by this Department.

The Department will require you to perform an investigation and, if necessary, remediation in accordance with Department of Environmental Control Title 118 - Ground Water Quality Standards and Use Classification Appendix A (enclosed). Costs related to the investigation/remediation of this spill may be eligible for reimbursement in accordance with Title 200 - Rules and Regulations for Petroleum Release Remedial Action Fund (enclosed). However, in order to be eligible for reimbursement, work must first receive prior approval by the Department.

Due to the volume of releases of this kind, the Department is currently prioritizing all new spills related to underground storage tank systems. When this site reaches the top of the priority list, a project manager will be assigned, and you or your company will be contacted with requirements to begin an investigation.

During the interim, you may begin an investigation/remediation. However, because it will not be under the direction of the Department, costs incurred will not be eligible for Title 200 reimbursement. You should also be aware that when this site reaches the top of the priority list and a project manager is assigned, the Department may require you to do work in addition to what you have already completed.

If at any time in the future, public safety is threatened by this spill, the State Fire Marshal (402/471-2027) and our office must be notified. Immediate action should be taken to eliminate the problem.

Please feel free to contact me at 402/471-4230 if you have any questions. Also, please contact me if your address or phone number changes. Thank you for your cooperation.

Sincerely,

Nancy Mann

CERTIFIED

RE: Petroleum release
Facility ID Number: S-1657 UG# 110993-NM-1430
Facility location: SITE# 172A, GRAND ISLAND

Dear THOMAS JAMIESON:

The Department has received the site assessment report for the closure of all or part of the underground storage tank system at the above referenced facility. Information in the report indicates that a release of petroleum resulting from the operation of this system has occurred. The purpose of this letter is to inform you, as the owner of the tank system, of your responsibilities in accordance with Neb. Rev. Stat. 81-15, 124 (Supp. 1989) for securing the release, identifying the affected environment, and completion of any remedial action required by this Department.

The Department will require you to perform an investigation and, if necessary, remediation in accordance with Department of Environmental Control Title 118 - Ground Water Quality Standards and Use Classification Appendix A (enclosed). Costs related to the investigation/remediation of this spill may be eligible for reimbursement in accordance with Title 200 - Rules and Regulations for Petroleum Release Remedial Action Fund (enclosed). However, in order to be eligible for reimbursement, work must first receive prior approval by the Department.

Due to the volume of releases of this kind, the Department is currently prioritizing all new spills related to underground storage tank systems. When this site reaches the top of the priority list, a project manager will be assigned, and you or your company will be contacted with requirements to begin an investigation.

During the interim, you may begin an investigation/remediation. However, because it will not be under the direction of the Department, costs incurred will not be eligible for Title 200 reimbursement. You should also be aware that when this site reaches the top of the priority list and a project manager is assigned, the Department may require you to do work in addition to what you have already completed.

If at any time in the future, public safety is threatened by this spill, the State Fire Marshal (402/471-2027) and our office must be notified. Immediate action should be taken to eliminate the problem.

Please feel free to contact me at 402/471-4230 if you have any questions. Also, please contact me if your address or phone number changes. Thank you for your cooperation.

Sincerely,

Nancy Mann
