SUMMARY

Problem

Achieving the objectives expressed in Operational Maneuver From the Sea (OMFTS) requires preparation for increased operational tempos that will permit rapid progress from ship to objective (1). Matching the increasing speed and mobility of assault forces requires the development of flexible, modular, and rapidly deployable Authorized Medical Allowance Lists (AMALs). Accomplishing this objective requires reducing the logistical footprint of the forward medical units without compromising the quality of clinical care.

Objective

The primary objective of the present study is to develop a model of the forward medical supply stream that links specific clinical requirements to individual medical treatment items. This process produces an audit trail for each item in the Marine Corps supply system. The audit trail provides medical planners and logisticians with a management tool for maintaining and updating supplies linking the AMAL materiel with Marine Corps specific requirements. In the present paper, scenario-specific requirements are also used to determine the optimal medical configuration necessary to support the Shock Surgical Team/Triage (SST) and Acute Care Ward functions of a Marine Corps Surgical Company.

Approach

One hundred twenty five clinical Subject Matter Experts (SMEs) with operational experience participated in the development of treatment profiles for the 319 Defense Medical Standardization Board (DMSB) Patient Conditions (PCs) (7). The PCs reflected the range of injuries, diseases and non-battle injuries known to occur in theater. From the treatment profiles, the specific medical tasks performed forward for each PC were identified. Then, the SMEs assigned the medical consumables and equipment to each task and its associated PC, establishing a clinical requirement for each piece of materiel. Once clinical requirements had been established, a patient generating model, PATGEN (9), was used to project the frequency of PCs likely to occur in a Major Regional Contingency (MRC). The casualty load projected by PATGEN, which reflects the number of each PC occurring, was then used as the input to a computer program that calculated the number of tasks needed to effectively treat the casualty load and the medical supplies required to perform the tasks. The supplies necessary to treat the casualty load were then organized into the proposed SST and Ward care AMALs.

Results

The two proposed AMAL blocks were compared to those currently used by operational forces. An examination of the results, shown in the table below, revealed significant reductions in the cube and weight for each of the AMALs. Furthermore, clinical capability was enhanced by the introduction of items that increased the number of treatment options available to medical providers in both the SST and the Acute Care Ward. An increased level of standardization was also achieved in the current study by incorporating tri-service approved materiel identified by the Defense Medical Standardization Board.

Percent Reductions in the Proposed AMALs when Compared to the Current AMALs

	Number of Items	Weight	Cubic Volume
SST – 631 Equipment	-23.2%	-31.9%	-41.2%
SST – 632 Consumables	-11.3%	-26.4%	-14.1%
Ward – 633 Equipment	-19.4%	-11.2%	-14.3%
Ward – 634 Consumables	-10.0%	-20.7%	-36.2%

Conclusion

Using the NHRC model has demonstrated that significant reductions in the logistical burden carried by Marine Corps forces can be achieved by modeling the clinically relevant elements of the theater of operations. The supply requirements for the delivery of medical care in far-forward medical areas have all been linked to the medical tasks requiring them. Supplies for these areas have been configured that reflect reductions in the weight and cube, without compromising the quality of care rendered.

This model can also be useful in determining the specific supply configurations for other missions and objectives. It is recommended that this model be used to identify supply requirements for the Marine Corps' Shock Trauma Platoon. Further, this model would also be useful in determining the appropriate type and number of supply items required for the delivery of sick call medical care. As Marine Corps doctrine requires more mobile, modular flexible and deployable medical systems, the NHRC model can be used in the configuration of medical supplies needed to achieve the objectives of a wide range of scenarios.

Using a Model of Clinical Events to Determine Supply Requirements for Marine Corps Shock Surgical Team/Triage (SST) and Acute Care Ward Units

INTRODUCTION

The nature of the U.S. Marine Corps mission is changing. The Marine Corps, as expressed in Operational Maneuver From the Sea (OMFTS), is evolving into a rapid reaction force, with a sea-based operational station that will allow rapid progress from ship to objective with no large or lengthy buildup on shore (1). Under the OMFTS concept, the tempo is expected to increase, making casualty triage and patient stabilization more difficult. Marine units are likely to be highly dispersed and very mobile, therefore casualties may occur in scattered pockets. These conditions will require medical support teams to be farther apart and rapidly deployable and their medical resources to be lighter, modular, and more flexible.

Moving units rapidly and effectively requires streamlining operations to improve responsiveness. This requirement to operate at a fast, fluid pace in these complex environments places unusual demands on medical responders in the field (2,3). Trauma in remote areas constitutes a complex process that must be carried out under fast-paced operations which are further complicated by inadequate patient histories, diagnostic tools, and logistic support. Timely and appropriate treatment may significantly improve the outcome of these casualties. For resuscitative emergencies that cannot wait for transportation to the rear, more sophisticated resources may be needed. Surgical units, however, must be small enough to perform abbreviated, staged surgical procedures in forward areas to accommodate today's operational requirements for greater battlefield mobility.

Matching the speed and mobility of assault forces requires the development of flexible, modular, and efficient Authorized Medical Allowance Lists (AMALs). Mission-specific standards of care and clinical requirements for the items pushed forward must be established so that only those items required to achieve the standards of care are transported. Accomplishing this objective requires reducing the logistical footprint of the forward resuscitative surgical function, without compromising the quality of clinical care rendered by the forward forces.

The Naval Health Research Center (NHRC) evaluated several Marine Corps supply blocks (laboratory, X-ray, Battalion Aid Station) and achieved significant reductions in materiel requirements by modeling the clinically relevant elements of the theater of operations. Only those items with an identified clinical requirement are included in the supply stream (4,5). Recently, an examination of the Operating Room AMALs was completed. The treatment profiles of 319 Patient Conditions (PCs) were examined.

Seventy-two PCs were identified as potential forward surgical candidates. Casualty projections were calculated for each surgical PC, and the supplies necessary to stabilize and resuscitate those PCs were generated. When compared with the current AMAL configurations, the proposed configuration achieved reductions in number of items, weight, and cube for both the equipment and consumable AMALs (6).

This model of the supply stream that links specific clinical requirements to individual medical treatment items was used in the present study to examine the Shock Surgical Team/Triage (SST) and the Acute Care ward AMALs. These areas are configured to render general surgical support (i.e., pre- and post-operative clinical functions). With the knowledge gained from evaluating the Operating Room AMALs, the clinical requirements for each supply item in the SST and Ward areas were established. Scenario-specific characteristics were used to generate the supply estimates for these two surgical support areas. Standardization of supply items among the SST and Ward care areas was addressed.

During reviews of the model and results obtained for Laboratory and X-ray supplies, Headquarters, Marine Corps (HQMC), Marine Corps Systems Command (MARCORSYSCOM), and the Defense Medical Standardization Board (DMSB) have voiced support for this approach. Consequently, MARCORSYSCOM AMAL program management and the Naval Medical Logistics Command, have worked diligently to incorporate changes generated using this approach into the AMAL lists. Further, the DMSB is using these reconfigured AMAL lists as a baseline to build a joint medical supply database. It is hoped that through continued cooperation substantial improvement in the AMALs can be achieved.

METHOD

The NHRC model was designed to interface with the Echelons III and IV Deployable Medical Systems (DEPMEDS) model (7). The DEPMEDS model, which consists of databases arranged in a relational structure called the "Time, Task, Treater" files, was developed to standardize medical materiel and to assemble it into sets so that each of the services could configure medical facilities according to its own unique requirements. The data in the DEPMEDS model are based on treatment protocols for 319 PCs, with each PC labeled with a short description and a number between 1 and 350. These PCs represent a grouping of closely related diagnoses, which are considered representative of the injuries expected to occur in theater (8). To build upon this existing standard, the structural characteristics of the Echelon I and II NHRC databases are compatible with those of the DEPMEDS Time, Task, Treater files.

Data Collection

Participants. One hundred twenty five medical clinicians experienced in combat casualty care participated in the study. These Subject Matter Experts (SMEs) were drawn from 20 Navy/Marine Corps commands (Table 1). The medical specialties within this group of

SMEs consisted of 49 physicians, surgeons and anesthesiologists, 6 physician's assistants, 1 pharmacist, 5 nurse anesthetists, 10 general care nurses, 18 surgical technicians, 13 laboratory and x-ray technicians and 23 Fleet Marine Force Corpsmen. Most SMEs had theater operational experience administering combat casualty care in the forward areas. The remaining SMEs had gained experience with the medical materiel under investigation through combat training exercises.

Procedures. The 350 DEPMEDS PCs form the core around which the NHRC Echelon I and II medical supply model was developed (see Appendix A for a complete list). The medical tasks required to treat these PCs at the three levels of care under investigation (Echelon Ia-Battlefield, Echelon Ib-Battalion Aid Station, and Echelon II-Surgical Company) were identified.¹ This process produced a preliminary step-by-step treatment protocol for each PC.

The next phase in development of the model required SMEs experienced in Marine Corps Echelon I and II medical care to (a) validate the treatment tasks and their assignments to the PCs, and (b) identify the appropriate consumable and equipment stream for each of

¹ Preliminary identification of the required tasks was conducted with support from the Army Medical Doctrine Development Center (AMEDD), Ft. Sam Houston, TX.

the tasks. To achieve this objective, surveys were constructed for each of the PCs and mailed to SMEs with operational field medical experience. The surveys returned were analyzed, and the PC-Task-Supply profiles modified².

The final step in assembling the major components of the model was to subject the PC-Task-Supply profiles to rigorous review by panels of clinical SMEs. The primary purpose of these panels was to validate the data gathered to ensure they reflected current Marine Corps medical doctrine and were representative of medical practice in an operational environment. Participants from the commands listed in Table 1 were contacted again and asked to participate in the panels. Each panel reviewed a portion of the model that best reflected the medical specialties of the panel members. For example, the composition of the clinical panels examining medical task-supply profiles for the Acute Care ward consisted primarily of nurses and surgeons. Once the clinical panels had completed their review of the PC-Task-Supply profiles, the model was ready to be used to project the medical supply requirements for specific operational scenarios.

Projecting Medical Supply Requirements

Medical supply estimates were projected for four AMAL blocks. These were the Shock Surgical Team/Triage (SST) equipment AMAL 631, the SST consumable AMAL 632, the Acute Care ward equipment AMAL 633, and the Acute Care ward consumable AMAL 634.

SST and Acute Care Ward AMAL functions. The SST equipment AMAL contains reusable materiel required to establish a shock surgical team or triage to support the receipt, resuscitation, and sorting of major casualties. The items in this block consist of medical instrumentation necessary to support two emergency medicine physicians and their staff of 29 physician's assistants, nurses, and corpsmen. Because this block consists of reusable materiel, it is designed to support an SST for an extended period of time.

The SST consumable AMAL is composed of single-use supplies required to receive, resuscitate, and sort 100 seriously wounded casualties. Because the materiel in this block is primarily disposable, it must be continually reordered to replenish supplies.

Items in the Acute Care ward equipment AMAL are reusable materiel required to establish a 20 bed unit providing care for both patients who can be returned to duty within the doctrinally defined time period and for post-operative casualties awaiting medical evacuation. The items in this block consist of medical instrumentation necessary to support two family practice physicians and their staff of 19 nurses and corpsmen.

² A more exhaustive description of the survey methodology can be found in Galarneau, Mahoney, Konoske, & Emens-Hesslink (1997)(5)

The Acute Care ward consumable AMAL is primarily composed of single-use items and is designed to provide ward support for 100 patient days. Because the items in this block are primarily disposable, they must be continually reordered to replenish supplies.

The AMAL blocks produced by the model in the current study were configured to achieve the same objectives as these four current Marine Corps blocks of equipment and consumable materiel.

Projecting equipment item requirements. Obtaining equipment estimates for the SST and Acute Care AMALs required that the clinical requirement for each item be established. This process was accomplished by linking each item considered for inclusion in the AMAL 631 and 633 to a known medical task to be conducted in either the SST or the Acute Care ward. Medical care items that could not be successfully related to an SST or Ward care task were eliminated from further consideration. Once each item in the two proposed equipment AMALs was identified, the amount of each item to be stocked was determined. For the SST, this was accomplished by matching item quantity with the requirement that the SST equipment block support two emergency medicine physicians and staff in an 8-patient shelter with overload capacity for mass casualty events. For the Acute Care ward, this was accomplished by matching item quantity with the requirement that the ward block support two family practice physicians and staff in a 10 medical bed, 10 post-surgical bed recovery unit.

Projecting consumable item requirements. As with the two equipment blocks, identifying the appropriate items to stock in both the SST and Ward consumable AMALs required that the clinical requirement for each item be established. Again, this was accomplished by ensuring that each consumable item had a clinical link to a known medical task to be conducted in either the SST or the Acute Care ward. Calculating the amount of each consumable item to stock, however, was accomplished differently than it was with the equipment blocks. Because consumable items are by definition patient driven, the amount of each required is highly dependent upon the characteristics of the patient stream. Therefore, advanced knowledge of casualty characteristics would allow for the configuration of a supply stream that is uniquely tailored to the number and type of casualties anticipated. In the present study, the types of PCs expected in theater were identified. The specific medical tasks associated with the care of each of these PCs at Echelon II were assigned as were the supplies needed to administer those tasks. Knowledge of the tasks and supplies required to treat each of the PCs provides sufficient data to project an optimum supply stream when the number of each PC anticipated is projected.

The Army's patient-generating model, PATGEN (U.S. Army Medical Department and School) (9), was used to obtain the projected number of PCs from which to estimate supply requirements. This model employs user-defined input, such as geographical location, battle intensity, troop mix, and rate of build-up, to project both the number of anticipated casualties and the distribution of PCs at each echelon of care from Ia through V. To project the appropriate supply mix for the maritime prepositioned force, two

separate runs of the PATGEN model were performed. One run produced the PC distribution for Major Regional Contingency (MRC) East and the second for MRC West. Both runs projected the casualty PC profiles for the first 60 days of a worst-case scenario conflict.

Examination of the distribution of PCs from both of the MRCs showed differences in the PC profiles. The differences in the number of PCs expected to present at a Surgical Company were particularly acute in the category of extremity and multiple injury wounds. To assure that the Maritime Preposition Force war reserve AMALs were adequately configured to support any anticipated contingency, modifications were made in the patient stream before loading it into the NHRC model. The objective of the modifications was to combine the anticipated casualty rates such that a single patient stream representative of both MRCs resulted. This was accomplished by examining each of the PCs and selecting the rate from the MRC with the highest frequency of occurrence.

The total sum of casualties presenting at the SST was calculated, resulting in 5,873 cases. This figure was lower than the 7,200 cases for which medical planners prepare. To ensure that the medical supplies produced by the NHRC model were tailored to the planned 7,200, each PC's casualty frequency was multiplied by a factor of 1.23 ($7,200/5,873$). In this way the likelihood of each PC presenting at the SST was equivalent for both casualty totals.

The total number of casualties presenting at the Ward was also calculated, resulting in a total of 11,886 patient days. Medical planners prepare for 11,700 patient days. Loading the higher number into the model would result in an insignificant overestimate of supply requirements. For this reason this number was used in all remaining calculations.

RESULTS AND DISCUSSION

SST and Ward PC Candidates

SMEs were provided criteria to apply in their determination of which PCs would be considered for treatment at either the SST or Acute Care ward. To qualify as a potential candidate for the SST, the SMEs were instructed to select only those PCs representing patients that were either seriously injured or experiencing a life-threatening event, such as anaphylaxis or myocardial infarction. PCs that required X-ray or laboratory diagnostic evaluation to determine whether to evacuate or to return to duty were also included. To qualify as a Ward candidate, SMEs were instructed to select only those PCs that represented patients that were either post-operative, awaiting medical evacuation, or that had a potential recovery time of less than 72 hours, such as superficial burns, sprain and strains, and minor surgical procedures. Based upon these criteria, the SMEs identified 236 potential SST candidates and 147 potential ward candidates. The list of these PCs is shown in Appendix A.

SST and Ward Care Tasks

A treatment profile that reflected the range of clinical care expected to be administered to casualties was developed by the SMEs for each of the SST and Ward PC candidates. An examination of each of these profiles revealed that the SMEs had identified 75 clinical tasks to be conducted in the SST and 56 tasks in the Acute Care ward (Table 2). The number of times a task was expected to be performed and the percentage of patients likely to receive the tasks were also estimated, where appropriate. For example, SMEs identified tasks that would likely be conducted once per patient, such as *Task 2014, Insert Endo-tracheal Tube* and other tasks, such as *Task 024, Measure Vital Signs*, which could be conducted multiple times during a clinical encounter. Furthermore, some tasks were best represented with a probability of occurrence because the treatment profiles contained clinical options that would not be uniformly applied. For example, SMEs did not always recommend that 100% of patients presenting with certain respiratory difficulties receive *Task 007, Emergency Cricothyroidotomy*. Rather, they assigned a probability that this clinical option would be taken in a certain percentage of cases. Using this approach, the NHRC model is better able to optimize supply projections.

Table 2
Medical Tasks Performed in the SST and Acute Care Ward

SST	Ward	Task Number & Description	SST	Ward	Task Number & Description
✓		001 Triage	✓	✓	125 Sponge/Hyperthermia Treatment
✓	✓	002 Assessment & Eval of Patient Status	✓	✓	126 Seizure Care/Precautions

SST and Ward Care Supplies

The SMEs further provided the specific medical equipment and consumable requirements for each of the tasks. Appendix B lists each task and the supplies required to administer care to each of the PCs in the SST. Appendix C lists each task and the supplies required to administer care to each of the PCs in the Acute Care ward. Where feasible, D-Day items, drawn from the approved DEPMEDS list of medical materiel, were used. It can be seen from Appendix B and C that some of the tasks have supply requirements that are the same regardless of the associated PC. For example, *Task 085, Wound Irrigation*, requires the same basic set of supplies regardless of the PC it is assigned. Other tasks, however, have supply requirements that vary considerably from PC to PC. For example, *Task 145, Administer Appropriate Medication*, produces supply requirements very specific to the PCs associated with it. These tasks, with PC-specific supply requirements are noted in both appendices.

SST (AMAL 631) and Acute Care Ward (AMAL 633) Equipment Requirements

Using the clinical links between the equipment items and the procedures requiring them, established by the SMEs, the SST equipment AMAL 631 and the Ward equipment AMAL 633 were produced. Appendix D shows the proposed AMAL 631, and Appendix E shows the proposed AMAL 633. Both AMAL lists show National Stock Number (NSN), item nomenclature, quantity of item required, item weight, and item cubic volume. Items that were added to upgrade clinical capability are marked with an asterisk.

When the composition of the two proposed AMALs had been determined, they were compared to the current Marine Corps SST and Ward care equipment AMALS. It can be seen in Table 3 that the proposed SST equipment AMAL contains 22 fewer items. This represents an item decrease of 23.2%. Reductions in the weight and cubic volume were also realized when compared with the current SST equipment block. Table 3 further shows that by establishing the clinical requirement for each item, weight could be reduced 31.9% and the cubic volume by 41.2%.

Table 3
Comparison Between Current and Proposed SST Equipment AMAL 631

	No. of Items	Weight	Cubic Volume
Current SST Equip	99	2094.4 lb	124.6 cu. ft.
Proposed SST Equip	77	1418.9 lb	72.9 cu. ft.
% Reduction	-23.2 %	-31.9%	-41.2 %

Table 4 shows the model results for the proposed Acute Care ward equipment AMAL. It can be seen from the table that the proposed equipment AMAL contains 13 fewer items, resulting in a reduction in item content of 21.0%. Reductions in weight and cube, while less dramatic than those in the SST, were also realized when compared to the current Ward equipment. Table 4 shows that by establishing the clinical requirement for each item, weight could be reduced by 11.2% and cubic volume by 14.3%. An examination of item content suggests that the lower estimated reductions can be attributed to the austerity of the current Ward equipment AMAL.

Table 4
Comparison Between Current and Proposed Acute Care Ward AMAL 633

	No. of Items	Weight	Cubic Volume
Current Ward Equip	62	633.6 lb	53.9 cu. ft.
Proposed Ward Equip	49	562.3 lb	46.3 cu. ft.
% Reduction	-19.4 %	-11.2%	-14.3 %

While significant reductions were realized in both of these AMALs, no decreases in clinical capability resulted. This occurred because the standard of care demanded by the SST and Ward care medical mission was not being met with some of the current equipment. As a result, items also had to be added to the blocks to upgrade the level of care provided. For example, improvements were incorporated in the suctioning systems, oxygen administration devices, pulse oximetry monitors, and defibrillators.

SST (AMAL 632) and Acute Care Ward (AMAL 634) Consumable Requirements

As with the equipment items, assigning the medical materiel to each of the tasks established the clinical requirement for each item of consumable materiel. This process provided the list of SST and Ward consumables that would be stocked in the proposed SST and Ward care AMALs. Furthermore, these are the items that were loaded into the model to determine the quantity of each to stock.

Determination of the quantity of each consumable to stock was accomplished by using the combined MRC East and West casualty projections. The combined MRC projections provided the number of anticipated casualties for each PC. These casualty projections were loaded into a computer program to determine the number of times each patient care task was expected to be conducted for each of the PCs. This procedure yielded the number and types of tasks that would need to be performed to effectively treat the projected casualty load. From the task output, the type of the medical materiel and the quantity required was derived using the supply assignments developed by the SMEs. Each consumable item required was summed using its NSN unit of measure then assembled into its NSN unit of issue packaging. The number of units of issue for each item of consumable materiel was the final value selected for inclusion in the proposed SST and Ward care consumable AMALs. Appendix F shows the proposed SST consumable AMAL 632, and Appendix G shows the proposed Acute Care ward consumable AMAL 634.

When the composition of the two proposed consumable AMALs had been determined, they were compared to the current Marine Corps SST and Ward care consumable AMALs. It can be seen from Table 5 that the proposed SST consumable AMAL contains 16 fewer items. This represents an item decrease of 11.3%. Reductions in the weight and cubic volume were also realized when compared with the current SST consumable block. Table 5 further shows that by establishing the clinical requirement for each item, weight could be reduced 26.4% and the cubic volume by 14.1%.

Table 5
Comparison Between Current and Proposed SST Consumable AMAL 632

	No. of Items	Weight	Cubic Volume
Current SST Consumables	141	870.2 lb	69.5 cu. ft.
Proposed SST Consumables	125	640.7 lb	59.7 cu. ft.
% Reduction	-11.3%	-26.4%	-14.1%

Table 6 shows the model results for the proposed Acute Care ward consumable AMAL. It can be seen from the table that the proposed consumable AMAL contains 9 fewer items,

resulting in a reduction in item content of 10.0%. Reductions in weight and cube were also realized when compared to the current Ward consumables. Table 6 shows that by establishing the clinical requirement for each item, weight could be reduced by 20.7% and cubic volume by 36.2%.

Table 6
Comparison Between Current and Proposed Ward Care Consumable AMAL 634

	No. of Items	Weight	Cubic Volume
Current Ward Consumables	90	937.0 lb	60.71 cu. ft.
Proposed Ward Consumables	81	747.3 lb	39.2 cu. ft.
% Reduction	-10%	-20.7%	-36.2%

While significant reductions in items, weight, and volume were realized, the clinical capability of the consumable SST and Ward care blocks was not decreased. Items deleted were limited to those that had no clinical requirement within the context of the SST and Ward care mission or which were redundant. Furthermore, because some procedures identified by the SMEs as critical to the SST and Ward were not being adequately performed with the current materiel, items were added to enhance the standard of care to a more desirable level. For example, newly added items not previously stocked in these blocks include nasopharyngeal airways, albumin, sodium chloride irrigant, newly developed chest seals to occlude sucking chest wounds, Ranitidine for post-surgical patients, and lightweight polymer splinting material.

CONCLUSIONS

Using the approach presented in the current study moves the Marine Corps forward in its efforts to achieve a lighter, faster, more flexible medical response as evolving doctrinal requirements demand. Cube and weight have been substantially reduced, permitting faster response times, greater flexibility, and reduced setup and take-down time. Equally important is the matter that no decrease in clinical capability resulted. Furthermore, the process permitted the identification of current deficiencies in providing care, such as, procedural requirements that could not be met with the existing stock of materiel. These issues were also addressed and responses implemented in the revised SST and Ward care AMALs.

The enhanced efficiencies of the revised AMALs occurred because items failing to yield a clinical relationship to SST or Ward medical practices were eliminated, thereby optimizing the value of the remaining materiel. Establishing the clinical requirement for each item also provided insight into areas of care not adequately met by items in the current AMALs. As SST and Ward procedures were identified, it became apparent that some of the current materiel was inadequate and therefore needed to be upgraded.

Because the approach used in this study examined the Battalion Aid Station and Surgical Company AMALs from the perspective of an integrated unit, the supplies assigned to each patient care area have been selected to provide continuity in the administration of care as a casualty progresses through the system. For example, the antimicrobial medications assigned to the SST and Operating Room AMALs are now also available in the Acute Care ward. In this way, surgeons can initiate a therapy in the SST or Operating Room confident that the therapy can be continued through the post-operative period without interruption. This integrated approach has also prevented unnecessary duplication of treatment options among the various AMALs. For example, it may not necessarily be clinically critical to stage refrigerators in both SST and Pharmacy when the SST only requires one of its medicinals (tetanus toxoid) to be refrigerated. Furthermore, this approach has provided the opportunity to standardize the materiel in the AMALs primarily using DMSB tri-service items. Now, instead of 4 different spineboards, each with its own NSN, all Marine Corps AMALs share a common item. This improves inventory efficiency and reduces training requirements by presenting medical providers with less variation in materiel.

Using the NHRC model has demonstrated that significant reductions in the logistical burden carried by Marine Corps forces can be achieved by modeling the clinically relevant elements of the theater of operations. The supply requirements for the delivery of medical care in far-forward medical areas have all been linked to the medical tasks requiring them. Supplies for these areas have been configured that reflect reductions in the weight and cube, without impacting the quality of care. This model can also be useful in determining the specific supply configurations for other missions and objectives. It is recommended that this model be used to identify supply requirements for the Marine Corps Shock Trauma Platoon. Further, this model would also be useful in determining the appropriate type and number of supply items required for the delivery of sick call medical care. As Marine Corps doctrine requires more mobile, modular flexible and deployable medical systems, the NHRC model can be used in the configuration of medical supplies needed to achieve the objectives of a wide range of scenarios.

13. ABSTRACT Moving toward a concept of medical organization that achieves the objectives of Marine Corps guidance such as <i>Operational Maneuver from the Sea</i> brings particular challenges when examining forward medical treatment facilities. These units must be small enough to perform abbreviated, staged resuscitative procedures in forward areas to accommodate today's operational requirements for greater mobility. The primary objective of this paper was to reduce the logistic footprint of the Shock Surgical Team/Triage (SST) and Acute Care Ward units by developing a model of the far forward medical supply stream that linked specific clinical requirements to individual medical treatment items. One hundred twenty five clinical Subject Matter Experts (SMEs) with operational experience assisted in the development of Marine Corps specific treatment profiles for 319 DEPMEDS Patient Conditions (PCs). Medical consumables and equipment were then assigned to each of the SST and Ward care tasks identified in the profiles, establishing the clinical requirement for each item. A patient generating model (PATGEN) was used to determine which PCs would present at an SST or require Ward care. This information was loaded into the model and used to generate the medical items required for the SST and Ward care blocks. When compared to the current Marine Corps SST and Ward care blocks, the proposed AMALs resulted in weight reductions of 31.9% and 26.4% for the SST equipment and consumable AMALs, respectively and 11.2% and 20.7% for the Ward equipment and consumable AMALs, respectively. Similar reductions were also realized in cubic volume. This approach, which also resulted in an increase in clinical capability, produced an audit trail for each item that allows medical logisticians to substantially improve the AMAL configurations because only items that can be clinically related to a treatment task conducted in theater are considered for inclusion.
