Abstract

Singleton kinds provide an elegant device for expressing type equality information resulting from modern module languages, but they can severely complicate the metatheory of languages in which they appear. I present a translation from a language with singleton kinds to one without, and prove that translation to be sound and complete. This translation is useful for type-preserving compilers generating typed target languages. The proof of soundness and completeness is done by normalizing type equivalence derivations using Stone and Harper's type equivalence decision procedure.

1 Introduction

Type-preserving compilation, compilation using statically typed intermediate languages, offers many compelling advantages over conventional untyped compilation. A typed compiler can utilize type information to enable optimizations that would otherwise be prohibitively difficult or impossible. Internal type checking can be used to help debug a compiler by catching errors introduced into programs in optimization or transformation stages. Finally, if preserved through the compiler to its ultimate output, types can be used to certify that executables are *safe*, that is, free of certain fatal errors or malicious behavior [10].

One major challenge that has arisen in extending type-preserving compilation to full-strength languages with modern module systems, such as Standard ML [8], is accounting for the propagation of type information. For example, consider the following SML signature:

```
signature SIG1 =
  sig
    type t = int
    val x : t
    val f : t -> t
  end
```

If *S* is a structure having signature SIG1, the compiler must remember that *S.t* is interchangeable with *int* throughout the remaining compilation process. However, it is unacceptable simply to treat *t* as a straight abbreviation and delete it from the signature, because SML's type system requires that SIG1 be a subsignature (*i.e.*, subtype) of the signature SIG2 obtained by removing the equality part of the specification:¹

```
signature SIG2 =
  sig
    type t
    val x : t
    val f : t -> t
  end
```

The TILT compiler in development at Carnegie Mellon University (the successor to the TIL compiler [16]) addresses this problem using *singleton kinds*, a very elegant and uniform type-theoretic mechanism for ensuring the propagation of type information. Kinds are used in type theories containing higher-order type constructors to classify type constructors just as types classify ordinary terms. Using singleton kinds, *S.t* is given the kind *S(int)*, the kind containing only the type *int* (and types equal to it). Propagation of type information is then obtained by augmenting the typechecker with the rule that if τ has kind *S(τ')*, then $\tau = \tau'$. The necessary subsignature relationship is obtained by observing that *S(int)* is a subkind of the kind *T* of all types. The management of type information for modules using formalisms similar to singleton kinds are explored in detail by Harper and Lillibridge [4] and Leroy [7].

Despite providing a very elegant solution to the type propagation problem, singleton kinds can substantially complicate type checking, for reasons discussed in Section 2. Stone and Harper [15] have recently shown that, despite these complications, type checking is decidable in the presence of singleton kinds, and indeed is decidable by a practical algorithm. However, the correctness proof for their algorithm is somewhat complicated.

As discussed above, a principal advantage of type-preserving compilation is the possibility of producing executables certified for safety by preserving types all the way through the compiler to its ultimate executable

¹This is not an arbitrary requirement in the design of SML. It is necessary to support a very common and useful idiom for code reuse: that of writing generic code predicated on an abstract signature, and constraining that abstract signature with the desired concrete types where the generic code is to be used.

kinds	$K ::= T \mid S(c) \mid \Pi\alpha:K_1.K_2 \mid \Sigma\alpha:K_1.K_2$
constructors	$c ::= \alpha \mid b \mid \lambda\alpha:K.c \mid c_1 c_2 \mid \langle c_1, c_2 \rangle \mid \pi_1 c \mid \pi_2 c$
assignments	$\Gamma ::= \epsilon \mid \Gamma, \alpha:K$

Figure 1: Syntax

output. This work was motivated by the desire to compile Standard ML (with its module language) to Typed Assembly Language (TAL) [10] for safety certification. However, the latter phases of a type-preserving compiler may involve complicated type systems including not only TAL, but also row polymorphism for stacks [9], inductive kinds for intentional type analysis [2], and types for tracking aliasing [14]. It is not clear whether Stone and Harper’s algorithm extends to these type systems augmented with singleton kinds, and if so, how easily its correctness can be proven. Moreover, there already exist a variety of tools for manipulating low-level typed languages that do not support singleton kinds.

I propose an alternative architecture for a type-preserving compiler for Standard ML that employs singleton kinds in the compiler’s front end, which performs ML-specific optimizations and transformations, but not in the back end, which may use complicated type systems for code generation and low-level transformations. This allows the back end to use singleton-free languages and tools, while still providing the full benefit of singleton kinds to the front end. However, for this to be possible, we require a way to eliminate singleton kinds without changing the meaning of the programs in which they appear.

In this paper I present such a strategy for singleton kind elimination. The singleton elimination process works by substituting definitions for free variables wherever singleton kinds give such definitions. This is intuitively a very attractive strategy, but it is complicated by some subtle issues arising from higher-order type constructors and its correctness is not trivial to prove.

The elimination strategy is correct (that is, sound and complete) in the following sense: if $\mathcal{J}$ is a judgement in the singleton kind calculus and $\mathcal{J}'$ is its corresponding judgement in the singleton free system (provided by the singleton elimination process), then $\mathcal{J}$ is derivable if and only if $\mathcal{J}'$ is derivable. This means that the elimination process does not cause any programs to cease to typecheck, nor does it allow any programs to typecheck that would not have before. The proof of this fact is the central technical contribution of the paper.

This paper is organized as follows: In Section 2, I formalize the singleton kind calculus and discuss some of its subtleties that make it complicated to work with. In Section 3, I present the singleton elimination strategy and state its correctness theorem. Section 4 is dedicated to the proof of the correctness theorem, and concluding remarks appear in Section 5.

This paper assumes familiarity with type systems with higher-order type constructors and dependent types. The correctness proof draws from the work of Stone and Harper [15] showing decidability of type equivalence in the presence of singleton kinds, but we will use their results almost entirely “off the shelf,” so familiarity with their paper is not required.

2 A Singleton Kind Calculus

We begin by formalizing the singleton calculus that is the subject of this paper. The syntax of the singleton calculus is given in Figure 1. It consists of a class of type constructors (usually referred to as “constructors” for brevity) and a class of kinds, which classify constructors. The class of constructors contains variables (ranged over by α), a collection of base types (ranged over by b), and the usual introduction and elimination forms for functions and pairs over constructors. We could also add a collection of primitive type operators

```

signature SIG3 =
  sig
    type s
    type t = int
    type u = s * t
    ... value fields ...
  end

funsig FSIG (S : sig
  type s
    ... value fields ...
end) =
  sig
    type t
    type u = S.s * t
    ... value fields ...
  end

```

Figure 2: Sample Signatures

(such as `list` or `->`) without difficulty, but have not done so in the interest of simplicity.

The kind structure is the novelty of the singleton calculus. The base kinds include T , the kind of all types, and $S(c)$, the kind of all types definitionally equal to c . Thus, $S(c)$ represents a singleton set, up to definitional equality. The constructor c in $S(c)$ is permitted to be open, and consequently kinds may contain free constructor variables, which makes it useful to have *dependent* kinds. The kind $\Pi\alpha:K_1.K_2$ contains functions from K_1 to K_2 , where α refers to the function's argument and may appear free in K_2 . Analogously, the kind $\Sigma\alpha:K_1.K_2$ contains pairs of constructors from K_1 and K_2 , where α refers to the left-hand member and may appear free in K_2 . As usual, when α does not appear free in K_2 , we write $\Pi\alpha:K_1.K_2$ as $K_1 \rightarrow K_2$ and $\Sigma\alpha:K_1.K_2$ as $K_1 \times K_2$.

In addition, the syntax provides a class of *assignments*, which assign kinds to free constructor variables, for use in the calculus's static semantics. In a practical application, the language would be extended with an additional class of terms, but for our purposes (which deal with constructor equality) we need not be concerned with terms, so they are omitted.

As usual, alpha-equivalent expressions (written $E \equiv E'$) are taken to be identical. The capture-avoiding substitution of c for α in E (where E is a kind, constructor or assignment) is written $E\{c/\alpha\}$. We also will often desire to define substitutions independent of a particular place of use, so when σ is a substitution, we denote the application of σ to the expression E by $E\{\sigma\}$. Separately defined substitutions will usually be written in the form $\{c_1/\alpha_1\} \cdots \{c_n/\alpha_n\}$, denoting a sequential substitution with the leftmost substitution taking place first.

As discussed in the introduction, the principal intended use of singleton kinds is in conjunction with module systems. For example, the type portion of signature `SIG3` in Figure 2 is translated to the kind:

$$\Sigma\alpha:T. \Sigma\beta:S(\text{int}). S(\alpha*\beta)$$

Note the essential use of dependent sums in this kind. Dependent products arise from the phase splitting [5] of functors. For example, after phase-splitting, the type portion of the functor signature `FSIG` in Figure 2 (given in the syntax of Standard ML of New Jersey version 110) is translated to the kind:

$$\Pi\alpha:T. (\Sigma\beta:T. S(\alpha*\beta))$$

2.1 Judgements

The inference rules defining the static semantics of the singleton calculus are given in Appendix A. A summary of the judgements that these rules define, and their interpretations, are given in Figure 3. For the most part, these are the usual rules for a dependently typed lambda calculus with products and sums (but lifted to the constructor level). Again, the novelty lies with the singleton kinds. Singleton kinds have two

Judgement	Interpretation
$\Gamma \vdash \text{ok}$	Γ is a valid assignment
$\vdash \Gamma_1 = \Gamma_2$	Γ_1 and Γ_2 are equivalent assignments
$\Gamma \vdash K$	K is a valid kind
$\Gamma \vdash K_1 \leq K_2$	K_1 is a subkind of K_2
$\Gamma \vdash K_1 = K_2$	K_1 and K_2 are equivalent kinds
$\Gamma \vdash c : K$	c is a valid constructor with kind K
$\Gamma \vdash c_1 = c_2 : K$	c_1 and c_2 are equivalent as members of kind K

Figure 3: Judgement Forms

introduction rules (one for kind assignment and one for equivalence),

$$\frac{\Gamma \vdash c : T}{\Gamma \vdash c : S(c)} \quad \frac{\Gamma \vdash c = c' : T}{\Gamma \vdash c = c' : S(c)}$$

and one elimination rule:

$$\frac{\Gamma \vdash c : S(c')}{\Gamma \vdash c = c' : T}$$

These rules capture the intuition of singleton kinds: The first says that any type belongs to its own singleton kind. The second says that equivalent types are also considered equivalent as members of their singleton kind. The third says that if one type belongs to another's singleton kind, then those types are equivalent.

The complexity of the singleton calculus arises from the above rules in conjunction with the subkinding relation generated by the following two rules:

$$\frac{\Gamma \vdash c : T}{\Gamma \vdash S(c) \leq T} \quad \frac{\Gamma \vdash c_1 = c_2 : T}{\Gamma \vdash S(c_1) \leq S(c_2)}$$

These rules are essential for singleton kinds to serve their intended purpose in a modern module system. The first allows a signature to match a supersignature obtained by remove equality specifications, as discussed in the introduction. The second allows a signature to match another signature obtained by replacing equality specifications with different but equivalent ones.

The presence of subkinding makes the usual context-insensitive methods of dealing with equivalence impossible. Consider the identity function, $\lambda\alpha:T.\alpha$, and the constant `int` function, $\lambda\alpha:T.\text{int}$. These functions are clearly inequivalent as members of $T \rightarrow T$; that is, the judgement $\vdash \lambda\alpha:T.\alpha = \lambda\alpha:T.\text{int} : T \rightarrow T$ is not derivable. However, since $T \rightarrow T$ is a subkind of $S(\text{int}) \rightarrow T$, these two functions can also be compared as members of $S(\text{int}) \rightarrow T$ and in that kind they *are* equivalent. This is because the bodies α and `int` are compared under the assignment $\alpha:S(\text{int})$, under which α and `int` are equivalent by the singleton elimination rule. This example makes it clear that to deal with constructor equivalence in the singleton calculus, one must take into account the contexts in which the constructors appear.

The determination of equivalence is further complicated by the fact that the classifying kind may be given *implicitly*. For example, the classifying kind may be imposed by a function on its argument. Consider the constructors $\beta(\lambda\alpha:T.\alpha)$ and $\beta(\lambda\alpha:T.\text{int})$. These are well-formed under an assignment giving β the kind $(T \rightarrow T) \rightarrow T$ and also under one giving β the kind $(S(\text{int}) \rightarrow T) \rightarrow T$. However, for the same reason as above, the two constructors are equivalent under the second assignment but not the first. The classifying kind can then be made even further remote by making β a function's formal argument instead of a free variable, and so on.

$$\begin{array}{lcl}
T^\circ & \stackrel{\text{def}}{=} & T \\
S(c)^\circ & \stackrel{\text{def}}{=} & T \\
(\Pi\alpha:K_1.K_2)^\circ & \stackrel{\text{def}}{=} & K_1^\circ \rightarrow K_2^\circ \\
(\Sigma\alpha:K_1.K_2)^\circ & \stackrel{\text{def}}{=} & K_1^\circ \times K_2^\circ
\end{array}$$

Figure 4: Singleton Erasure

2.2 A Singleton-Free System

To formalize our results, we also require a singleton-free target language into which to translate expressions from the singleton calculus. We will define the singleton-free system in terms of its differences from the singleton calculus:

We will say that a constructor c (not necessarily well-formed) syntactically belongs to the singleton-free calculus provided that c contains no singleton kinds. Note that as a consequence of containing no singleton kinds, all product and sum kinds may be written in non-dependent form. Also, all kinds in the singleton-free calculus are well-formed.

The inference rules for the singleton-free system are obtained by removing from the singleton calculus all the rules dealing with subkinding (Rules 9–13, 28 and 45) and all the rules dealing with singleton kinds (Rules 6, 15, 25, 34 and 35). Note that derivable judgements into the singleton-free system must be built using only expressions syntactically belonging to the singleton-free calculus. When a judgement is derivable in the singleton-free system, we will note this fact by marking the turnstile $\vdash_{sf}$.

3 Elimination of Singleton Kinds

The critical rule in the static semantics of the singleton calculus is the singleton elimination rule (Rule 34). The main aim of the singleton kind elimination process is to rewrite constructors so that any equivalences that hold for those constructors may be derived without using that rule. If this aim is achieved, any singleton kinds remaining within the constructors are not used (in any essential way) and can simply be erased, resulting in valid constructors and derivations in the singleton-free system.

This erasure process is made precise in Figure 4, which defines a mapping $(-)^{\circ}$ from singleton calculus kinds to singleton-free kinds that replaces all singleton kinds by T . The erasure mapping is lifted to constructors and assignments in the obvious manner. If $\Gamma \vdash c_1 = c_2 : K$ is derivable without using singleton elimination, then $\Gamma^\circ \vdash_{sf} c_1^\circ = c_2^\circ : K^\circ$ is derivable in the singleton-free system. A slightly stronger version of this fact is formalized as Lemma 25 in Section 4.4.

Thus, our goal is to rewrite constructor in such a manner that the singleton elimination rule is not necessary. As discussed in the introduction, this rewriting is done by substituting definitions for variables whenever singleton kinds provide such definitions. This works out quite simply in first-order cases, but higher-order cases raise some subtle issues. We will explore these issues by considering a number of examples before defining the fully general elimination process.

Example 1 Suppose we are working under the assignment $\alpha:S(\text{int}), \beta:S(\text{bool})$. Naturally, we replace all free appearances of α in the constructor in question by int , and replace all free appearances of β by bool . This is done simply by performing the substitution $\{\text{bool}/\beta\}\{\text{int}/\alpha\}$ on the constructor in question.

In this example, we refer to `int` as the *expansion* of α , and likewise `bool` is the expansion of β . In general, the elimination process will have the same gross structure as in this example. For an assignment $\Gamma = \alpha_1:K_1, \dots, \alpha_n:K_n$ we will define a substitution $R(\Gamma)$ of the form $\{c_n/\alpha_n\} \cdots \{c_1/\alpha_1\}$ where each c_i is the expansion of α_i .

Example 2 Suppose we are working under the assignment $\Gamma = \alpha:S(\text{int}), \beta:S(\alpha)$. In this case, analogously to the previous example, $R(\Gamma)$ is $\{\alpha/\beta\}\{\text{int}/\alpha\}$. Note that since this is a sequential substitution, it is equivalent to the substitution $\{\text{int}/\beta\}\{\text{int}/\alpha\}$, as one would expect.

Example 3 Suppose α is assigned the kind $S(\text{int}) \times S(\text{bool})$. In this case, $\pi_1\alpha$ is equal to `int` and $\pi_2\alpha$ is equal to `bool`. We can write these equalities into a constructor by substituting for α with the pair $\langle \text{int}, \text{bool} \rangle$.

Example 4 In the previous examples, the expansion of a variable α did not contain α , but this is not true in general. Suppose α is assigned the kind $T \times S(\text{int})$. In this case, $\pi_2\alpha$ is equal to `int`, but $\pi_1\alpha$ is not given a definition and should not be changed. We handle this by substituting for α with the pair $\langle \pi_1\alpha, \text{int} \rangle$.

As this example illustrates, a good way to understand expansions is to view them as eta-long forms of constructors. This interpretation is precisely correct, provided we view the replacement of a constructor by its singleton definition as an eta-expansion. In fact, the ultimate definition of expansions will eta-expand constructors uniformly, so, for example, if α has kind $T \times T$, its expansion will be $\langle \pi_1\alpha, \pi_2\alpha \rangle$ (instead of just α). This uniformity will make the correctness proof simpler, but a practical implementation would probably optimize such cases.

Example 5 Suppose α is assigned the kind $\Sigma\beta:T.S(\beta)$. Then $\pi_2\alpha$ is known to be equal to $\pi_1\alpha$ (although its precise value is unknown). In this case the expansion of α is $\langle \pi_1\alpha, \pi_1\alpha \rangle$.

Example 6 Suppose α is assigned the kind $\Sigma\beta:S(\text{int}).S(\beta)$. In this case $\pi_1\alpha$ and $\pi_2\alpha$ are equal to `int` and the expansion is $\langle \text{int}, \text{int} \rangle$.

Generally, if α has the kind $\Sigma\beta:K_1.K_2$, the expansion of α will be the pair $\langle c_1, c_2 \rangle$ where c_1 is the expansion of $\pi_1\alpha$, and c_2 is the expansion of $\pi_2\alpha$ *with the additional information* that β refers to $\pi_1\alpha$ and has kind K_1 . We may generalize all the examples so far with the following definition, where $R(c, K)$ is the expansion of c assuming c is known to have kind K :

$$\begin{aligned} R(c, T) &\stackrel{\text{def}}{=} c \\ R(c, S(c')) &\stackrel{\text{def}}{=} c' \\ R(c, \Sigma\alpha:K_1.K_2) &\stackrel{\text{def}}{=} \langle R(\pi_1c, K_1), R(\pi_2c, K_2\{R(\pi_1c, K_1)/\alpha\}) \rangle \end{aligned}$$

Example 7 Suppose α is assigned the kind $\Pi\beta:T.S(\text{list } \beta)$ (where $\text{list} : T \rightarrow T$). Then for any argument c , the application αc is equal to `list c`. Thus, the appropriate expansion of α is $\lambda\beta:T.\text{list } \beta$. Note that this is the eta-long form of `list`.

Example 8 Suppose α is assigned the kind $\Pi\beta:T.(T \times S(\beta))$. In this case, for any argument c , $\pi_2(\alpha c)$ is known to be equal to c , but no definition is given for $\pi_1(\alpha c)$. Thus, the expansion of α is $\lambda\beta:T.\langle \pi_1(\alpha \beta), \beta \rangle$.

These last two examples suggest the following generalization for product kinds:

$$R(c, \Pi\alpha:K_1.K_2) = \lambda\alpha:K_1. R(c\alpha, K_2) \quad (\text{wrong})$$

This is close to the right generalization, but, as we will see in the next section, it is not quite satisfactory due to the need to account for internally bound variables. Nevertheless, it provides good intuition on the process of expansion over product kinds.

3.1 Internally Bound Variables

Thus far we have exclusively considered rewriting constructors to account for the kinds of their free variables. To be sure that no uses of the singleton elimination rule are necessary, we must also consider internally bound variables. For example, it would seem as though the constructor $\lambda\alpha:S(\text{int}).\alpha$ should be rewritten to something like $\lambda\alpha:S(\text{int}).\text{int}$.

A naive approach would be to traverse the constructor in question and replace every bound variable with its expansion resulting from the kind in its binding occurrence. For example, in $\lambda\alpha:S(\text{int}).\alpha$, the binding occurrence of α gives it kind $S(\text{int})$, so the α in the abstraction's body would be replaced by $R(\alpha, S(\text{int})) \equiv \text{int}$. However this traversal is not sufficient to account for all internally bound variables, nor in fact is it even necessary.

To see why a traversal is insufficient, suppose β has kind $(S(\text{int}) \rightarrow T) \rightarrow T$ and consider the constructors $\beta(\lambda\alpha:T.\alpha)$ and $\beta(\lambda\alpha:T.\text{int})$. (Recall Section 2.1.) In the former constructor, the binding occurrence of α gives it kind T , and consequently the hypothetical traversal would not replace it. However, as we saw in Section 2.1, the two constructors should be equal, and for this to happen without the singleton elimination rule, α must be replaced by int in the former constructor. What this illustrates is that when an abstraction appears in an argument position, the abstraction's domain kind can be strengthened (in this case from T to $S(\text{int})$). This means that the kind given in a variable's binding occurrence cannot be relied upon.

One possibility for dealing with this would be to perform a much more complicated traversal that attempts to determine the "true" kind for every bound variable. Fortunately, we may deal with this in a much simpler way by shifting the responsibility for expanding a bound variable from the abstraction where that variable is bound to all constructors that might consume that abstraction.

In the above example, β changes the effective domain of its arguments to $S(\text{int})$; in other words, it promises only to call them with int . The expansion process for product kinds makes this explicit. In this case, the expansion of β is $\lambda\gamma:(S(\text{int}) \rightarrow T). \beta(\lambda\alpha:S(\text{int}).\gamma \text{int})$. After substituting this expansion for β , each of the constructors above normalize to $\beta(\lambda\alpha:S(\text{int}).\text{int})$. In general, the expansion that achieves this is:

$$R(c, \Pi\alpha:K_1.K_2) \stackrel{\text{def}}{=} \lambda\alpha:K_1. R(c\alpha, K_2)\{R(\alpha, K_1)/\alpha\}$$

Making this expansion part of the substitution for free variables accounts for all cases in which the kind of an abstraction (and therefore its domain kind) is given by some other constructor to which the abstraction is passed as an argument. The only other way a kind may be imposed on an abstraction is at the top level. Again recall Section 2.1 and consider the constructors $\lambda\alpha:T.\alpha$ and $\lambda\alpha:T.\text{int}$. These constructors should be considered equivalent when compared as members of kind $S(\text{int}) \rightarrow T$, but not as members of $T \rightarrow T$. Thus, the elimination process must be affected by the kinds in which a constructor is considered to lie.

This is neatly dealt with by (in addition to substituting expansions for free variables) expanding the entire constructor using the kind to which it belongs. Thus, when considered as members of $S(\text{int}) \rightarrow T$, the two constructors above become $\lambda\alpha:S(\text{int}).((\lambda\alpha:T.\alpha)\text{int})$ and $\lambda\alpha:S(\text{int}).((\lambda\alpha:T.\text{int})\text{int})$; each of which normalizes to $\lambda\alpha:S(\text{int}).\text{int}$. However, when considered as members of $T \rightarrow T$, the two become $\lambda\alpha:T.((\lambda\alpha:T.\alpha)\alpha)$ and $\lambda\alpha:T.((\lambda\alpha:T.\text{int})\alpha)$; each of which normalizes to its original form.

$$\begin{aligned}
R(c, T) &\stackrel{\text{def}}{=} c \\
R(c, S(c')) &\stackrel{\text{def}}{=} c' \\
R(c, \Pi\alpha:K_1.K_2) &\stackrel{\text{def}}{=} \lambda\alpha:K_1. R(c R(\alpha, K_1), K_2\{R(\alpha, K_1)/\alpha\}) \\
&\quad (\text{where } \alpha \text{ is not free in } c \text{ or } K_1) \\
R(c, \Sigma\alpha:K_1.K_2) &\stackrel{\text{def}}{=} \langle R(\pi_1 c, K_1), R(\pi_2 c, K_2\{R(\pi_1 c, K_1)/\alpha\}) \rangle \\
R(\alpha_1:K_1, \dots, \alpha_n:K_n) &\stackrel{\text{def}}{=} \{R(\alpha_n, K_n)/\alpha_n\} \cdots \{R(\alpha_1, K_1)/\alpha_1\}
\end{aligned}$$

Figure 5: Expansions

3.2 The Elimination Process

The full definition of the expansion constructors and substitutions is given in Figure 5. Using expansion, the singleton kind elimination proceeds in three steps: Given a constructor c considered to have kind K under assignment Γ , we first expand c , resulting in $R(c, K)$. Second, we substitute expansions for all free variables, resulting in $R(c, K)\{R(\Gamma)\}$. Third, we erase any remaining singleton kinds, resulting in $(R(c, K)\{R(\Gamma)\})^\circ$.

We may state the following correctness theorem for the elimination process, which states that rewritten constructors will be equivalent if and only if the original constructors were equivalent:

Theorem 1 *Suppose $\Gamma \vdash c_1 : K$ and $\Gamma \vdash c_2 : K$. Then $\Gamma \vdash c_1 = c_2 : K$ if and only if $\Gamma^\circ \vdash_{sf} (R(c_1, K)\{R(\Gamma)\})^\circ = (R(c_2, K)\{R(\Gamma)\})^\circ : K^\circ$.*

The proof of the correctness theorem is the subject of the next section.

4 Correctness Proof

The previous section's informal discussion motivates why we might expect the elimination process to be correct. Unfortunately, Theorem 1 defies direct proof, because there are too many ways that a judgement might be derived, and those derivations have no particular structure in common. We may see a reason why the proof is difficult by considering the theorem's implications. Since it is easy to determine equality of constructors in the singleton-free system, the theorem provides a simple test for equality: translate constructors into the singleton-free system and check that they are equal there. The theorem states that such a test is sound and complete. However, this also indicates that proving the theorem is at least as difficult as proving decidability of constructor equality in the full system.

The decidability of constructor equality has recently been shown by Stone and Harper [15]. They provide an algorithm for deciding constructor equality and prove that algorithm sound and complete using a Kripke-style logical relation. In addition to settling the decidability question, they provide a tool with which we may prove Theorem 1. One approach would be to follow Stone and Harper and prove the theorem directly using a logical relation. This approach is not attractive, due to the substantial complexity of the arguments involved. However, we may still take advantage of their result.

The proof works essentially by using Stone and Harper's algorithm to normalize the derivations of equality judgements. Given an derivable equality judgement, we use completeness of the algorithm to deduce the existence of a derivation in the *algorithmic system*. That derivation can have only one form, making it much easier to reason about.

The only-if portion of the proof (the difficult part) is structured as follows:

1. Suppose $\Gamma \vdash c_1 = c_2 : K$.
2. Prove that constructors are equal to their expansions; that is, $\Gamma \vdash c_1 = R(c_1, K)\{R(\Gamma)\} : K$ and $\Gamma \vdash c_2 = R(c_2, K)\{R(\Gamma)\} : K$. By symmetry and transitivity it follows that the expansions are equal: $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} = R(c_2, K)\{R(\Gamma)\} : K$.
3. By algorithmic completeness, deduce that there exists a derivation of the algorithmic judgement $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} : K \Leftrightarrow \Gamma \vdash R(c_2, K)\{R(\Gamma)\} : K$.
4. Prove that singleton reduction (the algorithmic counterpart of the singleton elimination rule) is not used in the algorithmic derivation. This step is the heart of the proof.
5. By algorithmic soundness, deduce that there exists a derivation of $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} = R(c_2, K)\{R(\Gamma)\} : K$ in which the singleton elimination rule (Rule 34) is not used (except within subderivations for kinding or subkinding judgements).
6. Prove that therefore there exists a derivation of $\Gamma^\circ \vdash_{sf} (R(c_1, K)\{R(\Gamma)\})^\circ = (R(c_2, K)\{R(\Gamma)\})^\circ : K^\circ$.

Once the only-if portion is proved, the converse is easily established. Its proof is discussed in Section 4.4.

4.1 Equality of expansions

We begin by establishing that well-formed constructors are equal to their expansions. We first state three propositions giving some properties of the inference system (these are proven in Stone and Harper [15]), and then prove equality of expansions by a series of three lemmas.

Proposition 2 (Regularity)

1. If $\Gamma \vdash \mathcal{J}$ then $\Gamma \vdash \text{ok}$.
2. If $\Gamma \vdash c : K$ then $\Gamma \vdash K \text{ kind}$.
3. If $\Gamma \vdash c_1 = c_2 : K$ then $\Gamma \vdash c_1 : K$ and $\Gamma \vdash c_2 : K$.

Proposition 3

1. **(Weakening)** If $\Gamma_1, \Gamma_3 \vdash \mathcal{J}$ and $\Gamma_1, \Gamma_2, \Gamma_3 \vdash \text{ok}$ then $\Gamma_1, \Gamma_2, \Gamma_3 \vdash \mathcal{J}$.
2. **(Reflexivity)** If $\Gamma \vdash c : K$ then $\Gamma \vdash c = c : K$.
3. **(Kind reflexivity)** If $\Gamma \vdash K \text{ kind}$ then $\Gamma \vdash K = K$.
4. **(Subkinding reflexivity)** If $\Gamma \vdash K_1 = K_2$ then $\Gamma \vdash K_1 \leq K_2$.
5. **(Assignment reflexivity)** If $\Gamma \vdash \text{ok}$ then $\vdash \Gamma = \Gamma$.

Proposition 4 (Substitution) Suppose $\Gamma \vdash c_1 = c_2 : K$. Then:

1. If $\Gamma, \alpha : K, \Gamma' \vdash K_1 = K_2$ then $\Gamma, (\Gamma'\{c_1/\alpha\}) \vdash K_1\{c_1/\alpha\} = K_2\{c_2/\alpha\}$.
2. If $\Gamma, \alpha : K, \Gamma' \vdash c'_1 = c'_2 : K'$ then $\Gamma, (\Gamma'\{c_1/\alpha\}) \vdash c'_1\{c_1/\alpha\} = c'_2\{c_2/\alpha\} : K'\{c_1/\alpha\}$.

Lemma 5 $R(c, K)\{c'/\alpha\} \equiv R(c\{c'/\alpha\}, K\{c'/\alpha\})$

Proof

By induction on K .

Lemma 6 *If $\Gamma \vdash c : K$ then $\Gamma \vdash c = R(c, K) : K$.*

Proof

By induction on K .

Case 1: Suppose $K \equiv T$. Then $R(c, K) \equiv c$ and by reflexivity, $\Gamma \vdash c = c : K$.

Case 2: Suppose $K \equiv S(c')$. Then $R(c, K) \equiv c'$. By assumption, $\Gamma \vdash c : S(c')$, so by singleton elimination (Rule 34), $\Gamma \vdash c = c' : T$. Then by symmetry and Rule 35, $\Gamma \vdash c = c' : S(c')$.

Case 3: Suppose $K \equiv \Pi\alpha:K_1.K_2$. Choose α so that it does not appear in the domain of Γ or free in c . Then $R(c, K) \equiv \lambda\alpha:K_1.R(cR(\alpha, K_1), K_2\{R(\alpha, K_1)/\alpha\})$. Invoking Lemma 5, $R(c, K) \equiv \lambda\alpha:K_1.R(c\alpha, K_2)\{R(\alpha, K_1)/\alpha\}$.

By regularity and inversion, $\Gamma \vdash K_1$ kind, so by weakening, $\Gamma, \alpha:K_1 \vdash c : \Pi\alpha:K_1.K_2$. Thus $\Gamma, \alpha:K_1 \vdash c\alpha : K_2$. By induction, $\Gamma, \alpha:K_1 \vdash c\alpha = R(c\alpha, K_2) : K_2$. Also by induction, $\Gamma, \alpha:K_1 \vdash \alpha = R(\alpha, K_1) : K_1$. Then, by weakening and substitution, $\Gamma, \alpha:K_1 \vdash c\alpha = R(c\alpha, K_2)\{R(\alpha, K_1)/\alpha\} : K_2$. By product introduction (Rule 40), $\Gamma \vdash \lambda\alpha:K_1.c\alpha = R(c, K) : \Pi\alpha:K_1.K_2$.

It remains to show that $\Gamma \vdash c = \lambda\alpha:K_1.c\alpha : \Pi\alpha:K_1.K_2$. This may be shown using functionality (Rule 30) and beta reduction (Rule 29).

Case 4: Suppose $K \equiv \Sigma\alpha:K_1.K_2$. Choose α so that it does not appear in the domain of Γ or free in c . Then $R(c, K) \equiv \langle R(\pi_1 c, K_1), R(\pi_2 c, K_2\{R(\pi_1 c, K_1)/\alpha\}) \rangle$. Note that by regularity and inversion, $\Gamma, \alpha:K_1 \vdash K_2$ kind.

By sum elimination (Rule 22), $\Gamma \vdash \pi_1 c : K_1$, so by induction, $\Gamma \vdash \pi_1 c = R(\pi_1 c, K_1) : K_1$. Also by sum elimination (Rule 23), $\Gamma \vdash \pi_2 c : K_2\{\pi_1 c/\alpha\}$. By reflexivity and substitution, $\Gamma \vdash K_2\{\pi_1 c/\alpha\} = K_2\{R(\pi_1 c, K_1)/\alpha\}$, and thus $\Gamma \vdash \pi_2 c : K_2\{R(\pi_1 c, K_1)/\alpha\}$. Then, by induction, $\Gamma \vdash \pi_2 c = R(\pi_2 c, K_2\{R(\pi_1 c, K_1)/\alpha\}) : K_2\{R(\pi_1 c, K_1)/\alpha\}$. By sum introduction (Rule 44) and symmetry, $\Gamma \vdash \langle \pi_1 c, \pi_2 c \rangle = R(c, K) : \Sigma\alpha:K_1.K_2$.

It remains to show that $\Gamma \vdash c = \langle \pi_1 c, \pi_2 c \rangle : \Sigma\alpha:K_1.K_2$. This may be shown using functionality (Rule 31) and beta reduction (Rules 32 and 33).

Lemma 7 *If $\Gamma \vdash c : K$ then $\Gamma \vdash c = R(c, K)\{R(\Gamma)\} : K$.*

Proof

The proof is by induction on Γ' that if $\Gamma, \Gamma' \vdash c : K$ then $\Gamma, \Gamma' \vdash c = R(c, K)\{R(\Gamma')\} : K$. For empty Γ' , use Lemma 6. In the inductive case, suppose $\Gamma' \equiv \alpha:K', \Gamma''$. Then $R(\Gamma') \equiv R(\Gamma'')\{R(\alpha, K')/\alpha\}$. By induction, $\Gamma, \alpha:K', \Gamma'' \vdash c = R(c, K)\{R(\Gamma'')\} : K$. Since $\Gamma, \alpha : K', \Gamma'' \vdash \alpha : K'$, by Lemma 6 it follows that $\Gamma, \alpha:K', \Gamma'' \vdash \alpha = R(\alpha, K') : K'$. By weakening and substitution, $\Gamma, \alpha:K', \Gamma'' \vdash c\{\alpha/\alpha\} = R(c, K)\{R(\Gamma'')\}\{R(\alpha, K')/\alpha\} : K$. That is, $\Gamma, \Gamma' \vdash c = R(c, K)\{R(\Gamma')\} : K$.

Corollary 8 *If $\Gamma \vdash c_1 = c_2 : K$ then $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} = R(c_2, K)\{R(\Gamma)\} : K$*

Proof

By regularity, Lemma 7, symmetry and transitivity.

4.2 The Decision Algorithm

Stone and Harper's decision algorithm for constructor equivalence is given in Figure 6. This algorithm is unusual in that it is a *six place* algorithm; it maintains two assignments and two kinds. This allows the two halves of the algorithm to operate independently, which is critical to Stone and Harper's proof and to this one.² In common usage, the two assignments and the two kinds are equivalent (but often not identical). The critical singleton reduction rule appears as the ninth clause.

The algorithm works as follows:

1. The algorithm is presented with a query of the form $\Gamma \vdash c : K \Leftrightarrow \Gamma' \vdash c' : K'$. When $\vdash \Gamma = \Gamma'$ and $\Gamma \vdash K = K'$, this determines whether $\Gamma \vdash c = c' : K$ is derivable.
2. The constructor equivalence rules add appropriate elimination forms (applications or projections) to the constructors being compared in order to drive them down to kind T or a singleton kind. Then those constructors are reduced to weak head normal form.
3. Elimination contexts (E) are defined in the usual manner, as shown below. A constructor of the form $E[\alpha]$ is referred to as a *path*, and α is called the *head* of the path. We will often use the metavariable p to range over paths.

$$E ::= [] \mid Ec \mid \pi_1 E \mid \pi_2 E$$

A constructor is reduced to weak head normal form by alternating beta reductions and singleton reductions. Beta reduction of a constructor c is performed by placing it in the form $E[c]$ where c is a beta redex, and reducing to $E[c']$ where c' is the corresponding contractum. Repetition of this will ultimately result in a path (if the constructor is well-formed, which is assumed).

4. Singleton reduction of a path p is performed by determining its *natural kind*, and replacing p with c whenever p 's natural kind is some singleton kind $S(c)$. (Formally, the algorithm adds an evaluation context, reducing $E[p]$ to $E[c]$ when p has natural kind c , but E will be empty when $E[p]$ is well-formed.) Note that the natural kind of a path is *not* a principal kind. For example, if $\Gamma(\alpha) = T$ then the natural kind of α is T , but α has principal kind $S(\alpha)$.
5. When no more beta or singleton reductions apply, the algorithm compares the two paths, checking that they have the same head variable and the same series of eliminations. When checking that two applications are the same, the main algorithm is reinvoked to determine whether the arguments are equal.

We may state the following correctness theorem for the algorithm:

Theorem 9 (Stone-Harper)

1. **(Completeness)** If $\Gamma \vdash c_1 = c_2 : K$ then $\Gamma \vdash c_1 : K \Leftrightarrow \Gamma \vdash c_2 : K$.
2. **(Soundness)** Suppose $\vdash \Gamma = \Gamma'$, $\Gamma \vdash K = K'$, $\Gamma \vdash c_1 : K$ and $\Gamma' \vdash c_2 : K'$. Then if $\Gamma \vdash c_1 : K \Leftrightarrow \Gamma' \vdash c_2 : K'$ then $\Gamma \vdash c_1 = c_2 : K$.

Corollary 10 If $\Gamma \vdash c_1 = c_2 : K$ then $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} : K \Leftrightarrow \Gamma \vdash R(c_2, K)\{R(\Gamma)\} : K$.

There is one minor difference between this algorithm and the one presented in Stone and Harper. When checking constructor equivalence at a singleton kind, Stone and Harper's algorithm immediately succeeds,

²Stone and Harper also prove their six-place algorithm equivalent to a conventional four-place algorithm, which is preferable in practice.

Natural kind extraction

$\Gamma \vdash \alpha \uparrow \Gamma(\alpha)$	
$\Gamma \vdash b \uparrow T$	
$\Gamma \vdash \pi_1 p \uparrow K_1$	if $\Gamma \vdash p \uparrow \Sigma\alpha:K_1.K_2$
$\Gamma \vdash \pi_2 p \uparrow K_2\{\pi_1 p/\alpha\}$	if $\Gamma \vdash p \uparrow \Sigma\alpha:K_1.K_2$
$\Gamma \vdash pc \uparrow K_2\{c/\alpha\}$	if $\Gamma \vdash p \uparrow \Pi\alpha:K_1.K_2$

Weak head reduction

$\Gamma \vdash E[(\lambda\alpha:K.c)c'] \longrightarrow E[c'/\alpha]$	
$\Gamma \vdash E[\pi_1\langle c_1, c_2 \rangle] \longrightarrow E[c_1]$	
$\Gamma \vdash E[\pi_2\langle c_1, c_2 \rangle] \longrightarrow E[c_2]$	
$\Gamma \vdash E[p] \longrightarrow E[c]$	if $\Gamma \vdash p \uparrow S(c)$ (singleton reduction)

Weak head normalization

$\Gamma \vdash c \Downarrow c'$	if $\Gamma \vdash c \longrightarrow c''$ and $\Gamma \vdash c'' \Downarrow c'$
$\Gamma \vdash c \Downarrow c$	otherwise

Algorithmic constructor equivalence

$\Gamma_1 \vdash c_1 : T \Leftrightarrow \Gamma_2 \vdash c_2 : T$	if $\Gamma_1 \vdash c_1 \Downarrow p_1$ and $\Gamma_2 \vdash c_2 \Downarrow p_2$ and $\Gamma_1 \vdash p_1 \uparrow T \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow T$
$\Gamma_1 \vdash c_1 : S(c'_1) \Leftrightarrow \Gamma_2 \vdash c_2 : S(c'_2)$	if $\Gamma_1 \vdash c_1 \Downarrow p_1$ and $\Gamma_2 \vdash c_2 \Downarrow p_2$ and $\Gamma_1 \vdash p_1 \uparrow T \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow T$
$\Gamma_1 \vdash c_1 : \Pi\alpha:K_1.K'_1 \Leftrightarrow \Gamma_2 \vdash c_2 : \Pi\alpha:K_2.K'_2$	if $\Gamma_1, \alpha:K_1 \vdash c_1\alpha : K'_1 \Leftrightarrow \Gamma_2, \alpha:K_2 \vdash c_2\alpha : K'_2$
$\Gamma_1 \vdash c_1 : \Sigma\alpha:K_1.K'_1 \Leftrightarrow \Gamma_2 \vdash c_2 : \Sigma\alpha:K_2.K'_2$	$\Gamma_1 \vdash \pi_1 c_1 : K_1 \Leftrightarrow \Gamma_2 \vdash \pi_1 c_2 : K_2$ and $\Gamma_1 \vdash \pi_2 c_1 : K'_1\{\pi_1 c_1/\alpha\} \Leftrightarrow \Gamma_2 \vdash \pi_2 c_2 : K'_2\{\pi_2 c_2/\alpha\}$

Algorithmic path equivalence

$\Gamma_1 \vdash \alpha \uparrow \Gamma_1(\alpha) \Leftrightarrow \Gamma_2 \vdash \alpha \uparrow \Gamma_2(\alpha)$	
$\Gamma_1 \vdash b_1 \uparrow T \Leftrightarrow \Gamma_2 \vdash b_2 \uparrow T$	if $b_1 \equiv b_2$
$\Gamma_1 \vdash p_1 c_1 \uparrow K'_1\{c_1/\alpha\} \Leftrightarrow \Gamma_2 \vdash p_2 c_2 \uparrow K'_2\{c_2/\alpha\}$	if $\Gamma_1 \vdash p_1 \uparrow \Pi\alpha:K_1.K'_1 \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow \Pi\alpha:K_2.K'_2$ and $\Gamma_1 \vdash c_1 : K_1 \Leftrightarrow \Gamma_2 \vdash c_2 : K_2$
$\Gamma_1 \vdash \pi_1 p_1 \uparrow K_1 \Leftrightarrow \Gamma_2 \vdash \pi_1 p_2 \uparrow K_2$	if $\Gamma_1 \vdash p_1 \uparrow \Sigma\alpha:K_1.K'_1 \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow \Sigma\alpha:K_2.K'_2$
$\Gamma_1 \vdash \pi_2 p_1 \uparrow K'_1\{\pi_1 p_1/\alpha\} \Leftrightarrow$ $\Gamma_2 \vdash \pi_2 p_2 \uparrow K'_2\{\pi_1 p_2/\alpha\}$	if $\Gamma_1 \vdash p_1 \uparrow \Sigma\alpha:K_1.K'_1 \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow \Sigma\alpha:K_2.K'_2$

Figure 6: Constructor Equivalence Algorithm

while the algorithm here behaves the same as when comparing at kind T . However, Stone and Harper's proof goes through in almost exactly the same way, with only a change to one subcase of their "Main Lemma." Their algorithm is more efficient, since it terminates early in some cases, but for our purposes we are not concerned with efficiency. The advantage of this version of the algorithm is that we may obtain the stronger version of soundness given in Theorem 12:

Definition 11 *A derivation is mostly free of singleton elimination if every use of singleton elimination (Rule 34) in that derivation lies within a subderivation whose root is a constructor formation or subkinding judgement.*

Theorem 12 (Singleton-free soundness) *Suppose $\vdash \Gamma = \Gamma'$, $\Gamma \vdash K = K'$, $\Gamma \vdash c_1 : K$ and $\Gamma' \vdash c_2 : K'$. Then if $\Gamma \vdash c_1 : K \Leftrightarrow \Gamma' \vdash c_2 : K'$ without using singleton reduction then there exists a derivation of $\Gamma \vdash c_1 = c_2 : K$ that is mostly free of singleton elimination.*

Proof

By inspection of Harper and Stone's proof.

Theorem 12 fails with the more efficient version of the algorithm because when $\Gamma_1 \vdash c_1 : S(c'_1) \Leftrightarrow \Gamma_2 \vdash c_2 : S(c'_2)$, the soundness proof must use singleton elimination to show that c_1 and c'_1 are equal and that c_2 and c'_2 are equal, in the course of showing that c_1 and c_2 are equal.

In the next section we will show that the algorithmic derivation shown to exist by Corollary 10 is free of singleton reduction. Then Theorem 12 will permit us to conclude that the corresponding derivation in the declarative system is mostly free of singleton elimination. A derivation mostly free of singleton elimination uses singleton elimination in no significant manner; any residual uses (within constructor formation or subkinding) will be removed by singleton erasure in Section 4.4.

4.3 Absence of singleton reduction

The heart of the proof is to show that singleton reduction will not be used in a derivation of algorithmic equivalence of expanded constructors. It is here that we really show that expansion works to eliminate singleton kinds: if the algorithm is able to deduce that the two expanded terms are equal without using singleton reduction, then we have obviated the need for singleton kinds.

The proof works by defining a condition, called *protectedness*, that is satisfied by expanded constructors, that rules out any need for singleton reduction, and that is preserved by the algorithm. First we make some preliminary definitions:

Definition 13

- Two kinds K and K' are similar (written $K \approx K'$) if they are the same modulo the contents of singleton kinds. That is, similarity is the least congruence such that $S(c) \approx S(c')$ for any constructors c and c' .
- Two assignments Γ and Γ' are similar (written $\Gamma \approx \Gamma'$) if they bind the same variables in the same order, and if $\Gamma(\alpha) \approx \Gamma'(\alpha)$ for all $\alpha \in \text{Dom}(\Gamma)$.

Note that a well-formed kind can be similar to an ill-formed kind, and likewise for assignments. When two kinds or two assignments are similar, they are said to have the same shape. For the proof of the absence of singleton reductions, we will be able to disregard the actual kinds and assignments being used and consider only their shapes; this will simplify the proof considerably. This works because the contents of singleton kinds are only pertinent to singleton reduction, which we are showing never takes place.

We also define *contexts* (C) as shown below. Note that contexts are defined to have exactly one hole, and note also that evaluation contexts are a subclass of contexts. As we are not concerned with the contents of singleton kinds, there is no need for contexts to account for constructors appearing within the domain kind of a lambda abstraction. Instantiation of a context is defined in the usual manner; in particular, it is permissible for instantiation to capture free variables.

$$C ::= [] \mid \lambda\alpha:K.C \mid Cc \mid cC \mid \langle C, c \rangle \mid \langle c, C \rangle \mid \pi_1 C \mid \pi_2 C$$

Finally, we define weak head reduction without a context in the usual manner (that is, $E[(\lambda\alpha:K.c)c'] \rightarrow E[c\{c'/\alpha\}]$ and $E[\pi_i\langle c_1, c_2 \rangle] \rightarrow E[c_i]$). Note that if $c_1 \rightarrow c_2$ then $\Gamma \vdash c_1 \rightarrow c_2$ (recall algorithmic weak head reduction).

We are now ready to define the protectedness property. The intuition is that a constructor is protected if every variable in that constructor appears in an evaluation context that drives it down to kind T . Consequently no path will have a singleton natural kind and singleton reduction will not take place. In order to ensure that protectedness is preserved by the algorithm, we strengthen the condition so that the evaluation context that drives a variable to kind T must be *appropriate*. An evaluation context is appropriate if, for every application appearing in that context, the argument constructor is protected (and, moreover, is still protected when driven to kind T and weak head normalized).

Definition 14 Suppose Γ is an assignment and K is a kind. The unary relations Γ -protected, K - Γ -appropriate, and K - Γ -protected are the least relations such that:

1. Protectedness

- A constructor c is Γ -protected if whenever $c \equiv C[\alpha]$ (where $\alpha \in \text{Dom}(\Gamma)$ and C does not capture α), there exist C' and E such that $C[\alpha] \equiv C'[E[\alpha]]$, and $E[\alpha]$ is T - Γ -appropriate.

2. Appropriateness

- A path α is K - Γ -appropriate if $\Gamma(\alpha) \approx K$.
- A path pc is K_2 - Γ -appropriate if p is $(\Pi\alpha:K_1.K_2)$ - Γ -appropriate and c is K_1 - Γ -protected.
- A path $\pi_1 p$ is K_1 - Γ -appropriate if p is $(\Sigma\alpha:K_1.K_2)$ - Γ -appropriate.
- A path $\pi_2 p$ is K_2 - Γ -appropriate if p is $(\Sigma\alpha:K_1.K_2)$ - Γ -appropriate.

3. Protectedness relative to a kind

- A constructor c is T - Γ -protected if c is Γ -protected.
- A constructor c is $S(c'')$ - Γ -protected if c is Γ -protected.
- A lambda abstraction $\lambda\alpha:K'_1.c$ is $(\Pi\alpha:K_1.K_2)$ - Γ -protected if c is K_2 - $(\Gamma, \alpha:K_1)$ -protected.
- A pair $\langle c_1, c_2 \rangle$ is $(\Sigma\alpha:K_1.K_2)$ - Γ -protected if c_1 is K_1 - Γ -protected and c_2 is K_2 - Γ -protected.

Note that the relations being defined appear only positively above, so Definition 14 is a valid inductive definition. Also, note that these definitions are concerned with kinds only up to similarity, and for this reason the definition can safely ignore the presence of free variables in kinds and assignments. We may immediately observe a number of easy structural facts about these definitions:

Lemma 15

1. Suppose $\Gamma \approx \Gamma'$ and $K \approx K'$, then

- c is Γ -protected if and only if c is Γ' -protected,
- c is K - Γ -protected if and only if c is K' - Γ' -protected, and
- p is K - Γ -appropriate if and only if p is K' - Γ' -appropriate.

2. If c is Γ -protected then $\lambda\alpha:K.c$, $\pi_1 c$, and $\pi_2 c$ are Γ -protected.

3. If c_1 and c_2 are Γ -protected then $c_1 c_2$ and $\langle c_1, c_2 \rangle$ are Γ -protected.

4. If $E[\lambda\alpha:K.c]$ is Γ -protected then c is Γ -protected.

5. If $E[c_1 c_2]$ is Γ -protected then c_2 is Γ -protected.

6. If $E[\langle c_1, c_2 \rangle]$ is Γ -protected, then c_1 and c_2 are Γ -protected.

7. Any constructor is ϵ -protected.

8. If c is $(\Gamma \setminus \alpha)$ -protected and α is not free in c , then c is Γ -protected.

9. If c is Γ -protected then c is $(\Gamma \setminus \alpha)$ -protected.

10. If c is K - Γ -protected then c is Γ -protected.

Proof

Parts 1–3 and 7–10 are by inspection. For part 4 observe that any path with its head in c lies entirely within c . Likewise for part 5 observe that any path with its head in c_2 lies entirely within c_2 , and similarly for part 6.

In order to show that protectedness is preserved by the algorithm, we need to show that it is preserved by weak head reduction. To show this we must first establish a substitution lemma. To do so, we will have need of the fact that any subexpression of a substitution results from one or the other participant in the substitution:

Lemma 16 *If $C[c] = c_1\{c_2/\alpha\}$ and C does not capture α then either*

- *there exist contexts C_1 and C_2 such that $c_1 \equiv C_1[\alpha]$, $c_2 \equiv C_2[c]$ and $C[] \equiv (C_1\{c_2/\alpha\})[C_2[]]$ (that is, c results from c_2), or*
- *there exists a context C_1 and a constructor c' such that $c_1 \equiv C_1[c']$, $c \equiv c'\{c_2/\alpha\}$, and $C[] \equiv (C_1\{c_2/\alpha\})[]$ (that is, c results from some c' in c_1).*

Proof

By induction on c_1 . If C is empty then the second case is satisfied by $C_1[] \equiv []$ and $c' \equiv c_1$. Therefore assume C is nonempty.

Case 1: Suppose $c_1 \equiv \alpha$. Then the first case is satisfied by $C_1[] \equiv []$ and $C_2[] \equiv C[]$.

Case 2: Suppose $c_1 \equiv \beta$ where $\beta \neq \alpha$. Then $C[c] \equiv \beta$, which is impossible since C is nonempty.

Case 3: Suppose $c_1 \equiv \lambda\beta:K.c'_1$. Then $C[] \equiv \lambda\beta:(K\{c_2/\alpha\}).(C'[])$. Since C does not capture α , it follows that $\beta \neq \alpha$. Note that $C'[c] \equiv c'_1\{c_2/\alpha\}$. We proceed by case analysis using the induction hypothesis on $C'[c]$:

Subcase 3.1: Suppose there exist contexts C'_1 and C_2 such that $c'_1 \equiv C'_1[\alpha]$, $c_2 \equiv C_2[c]$ and $C'[] \equiv (C'_1\{c_2/\alpha\})[C_2[]]$. Then the first case is satisfied by $C_1[] \equiv \lambda\beta:K.(C'_1[])$.

Subcase 3.2: Suppose there exists a context C'_1 and a constructor c' such that $c'_1 \equiv C'_1[c']$, $c \equiv c'\{c_2/\alpha\}$, and $C'[] \equiv (C'_1\{c_2/\alpha\})[]$. Then the second case is satisfied by $C_1[] \equiv \lambda\beta:K.(C'_1[])$.

Case 4: Suppose $c_1 \equiv c'_1 c''_1$. The remaining cases are similar. Then $C[]$ is either $(C'[])(c''_1\{c_2/\alpha\})$ or $(c'_1\{c_2/\alpha\})(C'[])$. Suppose the former; the latter is similar. Note that $C'[c] \equiv c'_1\{c_2/\alpha\}$. We proceed by case analysis using the induction hypothesis on $C'[c]$:

Subcase 4.1: Suppose there exist contexts C'_1 and C_2 such that $c'_1 \equiv C'_1[\alpha]$, $c_2 \equiv C_2[c]$ and $C'[] \equiv (C'_1\{c_2/\alpha\})[C_2[]]$. Then the first case is satisfied by $C_1[] \equiv (C'_1[])c''_1$.

Subcase 4.2: Suppose there exists a context C'_1 and a constructor c' such that $c'_1 \equiv C'_1[c']$, $c \equiv c'\{c_2/\alpha\}$, and $C'[] \equiv (C'_1\{c_2/\alpha\})[]$. Then the second case is satisfied by $C_1[] \equiv (C'_1[])c''_1$.

Lemma 17 (Substitution)

1. *If c_1 is Γ -protected and c_2 is Γ -protected, then $c_1\{c_2/\alpha\}$ is Γ -protected.*
2. *If p is K - Γ -appropriate, c_2 is Γ -protected and α is not the head of p , then $p\{c_2/\alpha\}$ is K - Γ -appropriate.*
3. *If c_1 is K - Γ -protected and c_2 is Γ -protected, then $c_1\{c_2/\alpha\}$ is K - Γ -protected.*

Proof

The proof is by induction on the derivation of the first assumption (i.e., c_1 being Γ -protected, p being K - Γ -appropriate, or c_1 being K - Γ -protected, respectively.) We show part 1; the other two parts are easy using an inner induction on K .

We may assume, without loss of generality, that $\alpha \notin \text{Dom}(\Gamma)$, if necessary by replacing α with a fresh variable and re-establishing protectedness of c_1 using Lemma 15 (parts 8 and 9). Suppose $C[\beta] \equiv c_1\{c_2/\alpha\}$, $\beta \in \text{Dom}(\Gamma)$, and C does not capture β . By assumption, $\alpha \neq \beta$, so we may alpha-vary $C[\beta]$ as necessary to ensure that C does not capture α . We proceed by case analysis using Lemma 16:

Case 1: Suppose $c_1 \equiv C_1[\alpha]$, $c_2 \equiv C_2[\beta]$ and $C[] \equiv (C_1\{c_2/\alpha\})[C_2[]]$. Since c_2 is Γ -protected, there exists C'_2 and E such that $C_2[] \equiv C'_2[E[]]$ and $E[\beta]$ is T - Γ -appropriate. Then $C[] \equiv C'[E[]]$ where $C'[]$ is $(C_1\{c_2/\alpha\})[C'_2[]]$.

Case 2: Suppose $c_1 \equiv C_1[c']$, $\beta \equiv c'\{c_2/\alpha\}$, $C[] \equiv (C_1\{c_2/\alpha\})[]$. The constructor c' must be either α or β . In the former case, $c_2 \equiv \beta$, and since c_2 is Γ -protected, it follows that protection is satisfied by setting C' to C and E to empty. Therefore, assume $c' \equiv \beta$.

Then c_1 is of the form $C_1[\beta]$ where C_1 does not capture β (since C does not). Since c_1 is Γ -protected, there must exist C'_1 and E such that $C_1[] \equiv C'_1[E[]]$ and $E[\beta]$ is T - Γ -appropriate. By induction, $E[\beta]\{c_2/\alpha\}$ is T - Γ -appropriate. Then $C[] \equiv C'[E'[]]$ where $C'[]$ is $(C'_1\{c_2/\alpha\})[]$ and E' is $(E\{c_2/\alpha\})[]$.

Corollary 18 *If c_1 is Γ -protected and $c_1 \longrightarrow c_2$ then c_2 is Γ -protected.*

Proof

We prove that if $E_{\text{out}}[c_1]$ is Γ -protected and $c_1 \longrightarrow c_2$ then c_2 is Γ -protected. The result follows by setting $E_{\text{out}} \equiv []$. Let c_1 be $E[c'_1]$ and c_2 be $E[c'_2]$, where c'_1 is a redex and c'_2 is its contractum. The proof is by induction on E .

Case 1: Suppose $E \equiv []$ and $c'_1 \equiv (\lambda\alpha:K.c)c'$. By Lemma 15 (parts 4 and 5), c and c' are Γ -protected. By Lemma 17, $c\{c'/\alpha\}$ is Γ -protected.

Case 2: Suppose $E \equiv []$ and $c'_1 \equiv \pi_i\langle c_1, c_2 \rangle$. By Lemma 15 (part 6), c_i is Γ -protected.

Case 3: Suppose $E \equiv E'c$. Then $E'[c'_1] \longrightarrow E'[c'_2]$ so, by induction, $E'[c'_2]$ is Γ -protected. By Lemma 15 (part 5), c is Γ -protected, so $E'[c'_2]c$ is Γ -protected.

Case 4: Suppose $E \equiv \pi_i E'$. Then $E'[c'_1] \longrightarrow E'[c'_2]$ so, by induction, $E'[c'_2]$ is Γ -protected. Thus $\pi_i E'[c'_2]$ is Γ -protected.

We will also need a technical lemma regarding natural kind extraction:

Lemma 19

1. *If p is K - Γ -appropriate and $\Gamma \vdash p \uparrow K'$ then $K \approx K'$.*
2. *If $\Gamma_1 \vdash p_1 \uparrow K_1 \leftrightarrow \Gamma_2 \vdash p_2 \uparrow K_2$ then $\Gamma_1 \vdash p_1 \uparrow K_1$ and $\Gamma_2 \vdash p_2 \uparrow K_2$.*

Proof

Part 1 is by induction on K . Part 2 is by induction on the derivation.

We are now ready to prove the main lemma:

Lemma 20 (Main Lemma)

1. *If $\Gamma_1 \vdash c_1 : K_1 \Leftrightarrow \Gamma_2 \vdash c_2 : K_2$ is derivable, $c_1 \longrightarrow^* c'_1$, $c_2 \longrightarrow^* c'_2$, c'_1 is K_1 - Γ_1 -protected, and c'_2 is K_2 - Γ_2 -protected, then the derivation does not use singleton reduction.*
2. *If $\Gamma_1 \vdash p_1 \uparrow K_1 \leftrightarrow \Gamma_2 \vdash p_2 \uparrow K_2$ is derivable, c_1 is K_1 - Γ_1 -appropriate, and c_2 is K_2 - Γ_2 -appropriate, then the derivation does not use singleton reduction.*

Proof

By induction on the algorithmic derivation.

Case 1: Suppose the derivation's root is $\Gamma_1 \vdash c_1 : T \Leftrightarrow \Gamma_2 \vdash c_2 : T$. Then $\Gamma_1 \vdash c_1 \Downarrow p_1$, $\Gamma_2 \vdash c_2 \Downarrow p_2$, and $\Gamma_1 \vdash p_1 \uparrow T \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow T$. By the definitions of weak head normalization and reduction, it follows either that $c_1 \rightarrow^* p_1$ or that $c_1 \rightarrow^* E[p'_1]$, $\Gamma_1 \vdash p'_1 \uparrow S(c'_1)$, and $\Gamma_1 \vdash E[c'_1] \Downarrow p_1$. In either case c_1 beta weak head reduces to a path, so let $c_1 \rightarrow^* p$. Since weak head reduction is deterministic and p is in (beta) weak head normal form, it follows that $c'_1 \rightarrow^* p$. By assumption c'_1 is Γ_1 -protected, so by Corollary 18, p is Γ_1 -protected.

Suppose p singleton reduces and let p be $E[\alpha]$. Then there exist E_1 and E_2 such that $E[] \equiv E_1[E_2[]]$ and $\Gamma_1 \vdash E_2[\alpha] \uparrow S(c)$. Since p is Γ_1 -protected, there also exist E'_1 and E'_2 such that $E[] \equiv E'_1[E'_2[]]$ and $E'_2[\alpha]$ is T - Γ_1 -appropriate. One of $E_2[\alpha]$ and $E'_2[\alpha]$ must be a subpath of the other and both cases lead to a contradiction. If $E'_2[\alpha]$ is a subpath of $E_2[\alpha]$ then $\Gamma_1 \vdash E'_2[\alpha] \uparrow K$ for some K , but $K \approx T$ by Lemma 19 so it cannot be the case that $\Gamma_1 \vdash E_2[\alpha] \uparrow S(c)$. If $E_2[\alpha]$ is a subpath of $E'_2[\alpha]$ then $E_2[\alpha]$ is K - Γ_1 -appropriate for some K , but $K \approx S(c)$ by Lemma 19 so it cannot be the case that $E'_2[\alpha]$ is T - Γ_1 -appropriate.

Hence p does not singleton reduce, and consequently $c_1 \rightarrow^* p_1$ and p_1 is Γ_1 -protected. Again let p_1 be $E[\alpha]$. Since p_1 is Γ_1 -protected, there exist E_1 and E_2 such that $E[] \equiv E_1[E_2[]]$ and $E_2[\alpha]$ is T - Γ_1 -appropriate. Since $\Gamma_1 \vdash E_1[E_2[\alpha]] \uparrow T \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow T$, by Lemma 19 (part 1) $\Gamma_1 \vdash E_1[E_2[\alpha]] \uparrow T$, and therefore that $\Gamma_1 \vdash E_2[\alpha] \uparrow K$ for some K . By Lemma 19 (part 2), $K \approx T$, which means that E_1 must be empty. Therefore, p_1 is T - Γ_1 -appropriate. Similarly $c_2 \rightarrow^* p_2$ and p_2 is T - Γ_2 -appropriate. The result follows by induction.

Case 2: Suppose the derivation's root is $\Gamma_1 \vdash c_1 : S(c'_1) \Leftrightarrow \Gamma_2 \vdash c_2 : S(c'_2)$. This case is identical to the previous case.

Case 3: Suppose the derivation's root is $\Gamma_1 \vdash c_1 : \Pi\alpha:K_{11}.K_{12} \Leftrightarrow \Gamma_2 \vdash c_2 : \Pi\alpha:K_{21}.K_{22}$. By assumption, $c_1 \rightarrow^* c'_1$ and c'_1 is of the form $\lambda\alpha:K'_{11}.c''_1$ where c''_1 is K_{12} - $(\Gamma_1, \alpha:K_{11})$ -protected. Then $c_1\alpha \rightarrow^* c'_1$. Similarly, $c_2\alpha \rightarrow^* c'_2$ for some K_{22} - $(\Gamma_2, \alpha:K_{21})$ -protected c'_2 . The result follows by induction.

Case 4: Suppose the derivation's root is $\Gamma_1 \vdash c_1 : \Sigma\alpha:K_{11}.K_{12} \Leftrightarrow \Gamma_2 \vdash c_2 : \Sigma\alpha:K_{21}.K_{22}$. By assumption, $c_1 \rightarrow^* c'_1$ and c'_1 is of the form $\langle c_{11}, c_{12} \rangle$ where c_{11} is K_{11} - Γ_1 -protected and c_{12} is K_{12} - Γ_1 -protected. Then $\pi_1 c_1 \rightarrow^* c_{11}$ and $\pi_2 c_1 \rightarrow^* c_{12}$. Since $K_{12} \approx K_{12}\{\pi_1 c_1 / \alpha\}$, it follows that c_{12} is $(K_{12}\{\pi_1 c_1 / \alpha\})$ - Γ_1 -protected. Similarly, $\pi_1 c_2 \rightarrow^* c_{21}$ and $\pi_2 c_2 \rightarrow^* c_{22}$ for some K_{21} - Γ_2 -protected c_{21} and some $(K_{22}\{\pi_1 c_2 / \alpha\})$ - Γ_2 -protected c_{22} . The result follows by induction.

Case 5: Suppose the derivation's root is $\Gamma_1 \vdash \alpha \uparrow \Gamma_1(\alpha) \Leftrightarrow \Gamma_2 \vdash \alpha \uparrow \Gamma_2(\alpha)$. The result follows trivially.

Case 6: Suppose the derivation's root is $\Gamma_1 \vdash b \uparrow T \Leftrightarrow \Gamma_2 \vdash b \uparrow T$. The result follows trivially.

Case 7: Suppose the derivation's root is $\Gamma_1 \vdash p_1 c_1 \uparrow K_{12}\{c_1 / \alpha\} \Leftrightarrow \Gamma_2 \vdash p_2 c_2 \uparrow K_{22}\{c_2 / \alpha\}$. Then $\Gamma_1 \vdash p_1 \uparrow \Pi\alpha:K_{11}.K_{12} \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow \Pi\alpha:K_{21}.K_{22}$ and $\Gamma_1 \vdash c_1 : K_{11} \Leftrightarrow \Gamma_2 \vdash c_2 : K_{21}$. Since (invoking Lemma 15 (part 1)) $p_1 c_1$ is K_{12} - Γ_1 -appropriate, it follows that p_1 is $(\Pi\alpha:K'_{11}.K_{12})$ - Γ_1 -appropriate and c_1 is K'_{11} - Γ_1 -protected, for some K'_{11} . However, by Lemma 19 it follows that $K_{11} \approx K'_{11}$. Thus, p_1 is $(\Pi\alpha:K_{11}.K_{12})$ - Γ_1 -appropriate and c_1 is K_{11} - Γ_1 -protected. Similarly, p_2 is $(\Pi\alpha:K_{21}.K_{22})$ - Γ_2 -appropriate and c_2 is K_{21} - Γ_2 -protected. The result follows by induction.

Case 8: Suppose the derivation's root is $\Gamma_1 \vdash \pi_1 p_1 \uparrow K_{11} \Leftrightarrow \Gamma_2 \vdash \pi_1 p_2 \uparrow K_{21}$. Then $\Gamma_1 \vdash p_1 \uparrow \Sigma\alpha:K_{11}.K_{12} \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow \Sigma\alpha:K_{21}.K_{22}$. Since $\pi_1 p_1$ is K_{11} - Γ_1 -appropriate, it follows that p_1 is $(\Sigma\alpha:K_{11}.K'_{12})$ - Γ_1 -appropriate. However, by Lemma 19 it follows that $K_{12} \approx K'_{12}$. Thus, p_1 is $(\Sigma\alpha:K_{11}.K_{12})$ - Γ_1 -appropriate. Similarly, p_2 is $(\Sigma\alpha:K_{21}.K_{22})$ - Γ_2 -appropriate. The result follows by induction.

Case 9: Suppose the derivation's root is $\Gamma_1 \vdash \pi_2 p_1 \uparrow K_{12}\{\pi_1 p_1 / \alpha\} \Leftrightarrow \Gamma_2 \vdash \pi_2 p_2 \uparrow K_{22}\{\pi_1 p_2 / \alpha\}$. Then $\Gamma_1 \vdash p_1 \uparrow \Sigma\alpha:K_{11}.K_{12} \Leftrightarrow \Gamma_2 \vdash p_2 \uparrow \Sigma\alpha:K_{21}.K_{22}$. Since (invoking Lemma 15 (part 1)) $\pi_2 p_1$ is K_{12} - Γ_1 -appropriate, it follows that p_1 is $(\Sigma\alpha:K'_{11}.K_{12})$ - Γ_1 -appropriate. However, by Lemma 19 it follows that $K_{11} \approx K'_{11}$. Thus, p_1 is $(\Sigma\alpha:K_{11}.K_{12})$ - Γ_1 -appropriate. Similarly, p_2 is $(\Sigma\alpha:K_{21}.K_{22})$ - Γ_2 -appropriate. The result follows by induction.

It remains to show that expanded constructors are protected.

Definition 21

- The kind T is Γ -protected.
- The kind $S(c)$ is Γ -protected if c is.
- The kinds $\Pi\alpha:K_1.K_2$ and $\Sigma\alpha:K_1.K_2$ are Γ -protected if both K_1 and K_2 are.

Lemma 22

1. If p is K - Γ -appropriate and K is Γ -protected then $R(p, K)$ is Γ -protected.
2. If c and K are Γ -protected then $R(c, K)$ is K - Γ -protected.

Proof

By induction on K .

Case 1: Suppose $K \equiv T$. Part 2 is trivial. For part 1, we wish to show that p is Γ -protected. Let p be $E[\alpha]$ and suppose $p \equiv C[\beta]$. If $C \equiv E$ then the result is immediate. Otherwise C chooses β from within one of the argument positions in the path. That is, $E[] \equiv E_1[(E_2[])](C'[\beta])$ and $C[] \equiv E_1[(E_2[\alpha])(C'[])]$. Since p is T - Γ -appropriate, $C'[\beta]$ is K' - Γ -protected (for some K'), and thus is $C'[\beta]$ is Γ -protected. Hence there exist C'' and E' such that $C'[] \equiv C''[E'[]]$ and $E'[\beta]$ is T - Γ -appropriate. The result follows choosing $E_1[(E_2[\alpha])(C'[])]$ for the outer context and E' for the inner.

Case 2: Suppose $K \equiv S(c')$. Both parts are trivial, since c' is Γ -protected.

Case 3: Suppose $K \equiv \Pi\alpha:K_1.K_2$. Assume, without loss of generality, that $\alpha \notin \text{Dom}(\Gamma)$ and α is not free in c . Then α is trivially K_1 - $(\Gamma, \alpha:K_1)$ -appropriate. Therefore, by induction, $R(\alpha, K_1)$ is $(\Gamma, \alpha:K_1)$ -protected. By Lemma 17 (and an easy induction over K_2), it follows that $K_2\{R(\alpha, K_1)/\alpha\}$ is $(\Gamma, \alpha:K_1)$ -protected. Using Lemma 15, $K_2\{R(\alpha, K_1)/\alpha\}$ is also Γ -protected.

1. Since $\alpha \notin \text{Dom}(\Gamma)$, α is Γ -protected. By induction, $R(\alpha, K_1)$ is K_1 - Γ -protected. Thus $p R(\alpha, K_1)$ is K_2 - Γ -appropriate. By induction, $R(p R(\alpha, K_1), K_2\{R(\alpha, K_1)/\alpha\})$ is Γ -protected. By Lemma 15, $R(p, K) \equiv \lambda\alpha:K_1.R(p R(\alpha, K_1), K_2\{R(\alpha, K_1)/\alpha\})$ is Γ -protected.
2. Since α is not free in c , by Lemma 15 c is $(\Gamma, \alpha:K_1)$ -protected. Thus $c R(\alpha, K_1)$ is $(\Gamma, \alpha:K_1)$ -protected. By induction $R(c R(\alpha, K_1), K_2\{R(\alpha, K_1)/\alpha\})$ is K_2 - $(\Gamma, \alpha:K_1)$ -protected. Hence $R(c, K)$ is K - Γ -protected.

Case 4: Suppose $K \equiv \Sigma\alpha:K_1.K_2$.

1. By definition, $\pi_1 p$ is K_1 - Γ -appropriate and $\pi_2 p$ is K_2 - Γ -appropriate. By induction, $R(\pi_1 p, K_1)$ is Γ -protected. By Lemma 17, $K_2\{R(\pi_1 p, K_1)/\alpha\}$ is Γ -protected, so by induction, $R(\pi_2 p, K_2\{R(\pi_1 p, K_1)/\alpha\})$ is Γ -protected. By Lemma 15, $R(p, K) \equiv \langle R(\pi_1 p, K_1), R(\pi_2 p, K_2\{R(\pi_1 p, K_1)/\alpha\}) \rangle$ is Γ -protected.
2. By Lemma 15, $\pi_1 c$ and $\pi_2 c$ are Γ -protected. By induction, $R(\pi_1 c, K_1)$ is K_1 - Γ -protected. Therefore $R(\pi_1 c, K_1)$ is also Γ -protected, so by Lemma 17, $K_2\{R(\pi_1 c, K_1)/\alpha\}$ is Γ -protected. By induction $R(\pi_2 c, K_2\{R(\pi_1 c, K_1)/\alpha\})$ is K_2 - Γ -protected. Hence $R(c, K)$ is K - Γ -protected.

Lemma 23 If $\Gamma \vdash \text{ok}$ then $R(c, K)\{R(\Gamma)\}$ is K - Γ -protected.

Proof

Observe first that since $\Gamma \vdash \text{ok}$, whenever $\Gamma \equiv \Gamma_1, \alpha:K', \Gamma_2$, neither α nor any variable in $\text{Dom}(\Gamma_2)$ can appear free in K' . We claim that for any c' , $c'\{R(\Gamma)\}$ is Γ -protected. By Lemma 5, $R(c, K)\{R(\Gamma)\} \equiv R(c\{R(\Gamma)\}, K\{R(\Gamma)\})$. It follows from the claim that $c\{R(\Gamma)\}$ and $K\{R(\Gamma)\}$ are Γ -protected, and therefore, by Lemma 22, $R(c\{R(\Gamma)\}, K\{R(\Gamma)\})$ is $(K\{R(\Gamma)\})$ - Γ -protected. Then $R(c\{R(\Gamma)\}, K\{R(\Gamma)\})$ is K - Γ -protected as well, since $K \approx K\{R(\Gamma)\}$.

We prove the claim by induction on Γ . The base case is trivial. Suppose then $\Gamma \equiv \alpha : K', \Gamma'$. By induction, $c'\{R(\Gamma')\}$ is Γ' -protected. By the initial observation, neither α nor any variable in $\text{Dom}(\Gamma')$ is free in K' . Therefore K' is Γ -protected. Also $\Gamma(\alpha) \equiv K'$ so α is K' - Γ -appropriate. By Lemma 22, $R(\alpha, K')$ is Γ -protected. We cannot immediately claim by Lemma 17 that $c'\{R(\Gamma)\}$ is Γ -protected, since $c'\{R(\Gamma')\}$ may contain free occurrences of α and thus might not be Γ -protected. However, any such occurrences are nonessential, since they will only be substituted away. We make this explicit with a change of variables. Let β be fresh. Then by changing variables we obtain:

$$\begin{aligned} c'\{R(\Gamma)\} &\equiv c'\{R(\Gamma')\}\{R(\alpha, K')/\alpha\} \\ &\equiv c'\{R(\Gamma')\}\{\beta/\alpha\}\{R(\alpha, K')/\beta\} \end{aligned}$$

Then $c'\{R(\Gamma')\}\{\beta/\alpha\}$ is Γ -protected, since it does not contain α free. Therefore, by Lemma 17, $c'\{R(\Gamma)\}$ is Γ -protected.

Corollary 24 *If $\Gamma \vdash c_1 = c_2 : K$ then there exists a derivation of $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} = R(c_2, K)\{R(\Gamma)\} : K$ that is mostly free of singleton elimination.*

Proof

Suppose $\Gamma \vdash c_1 = c_2 : K$. By regularity, $\Gamma \vdash \text{ok}$. By Corollary 10, $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} : K \Leftrightarrow \Gamma \vdash R(c_2, K)\{R(\Gamma)\} : K$. By Lemma 23, both $R(c_1, K)\{R(\Gamma)\}$ and $R(c_2, K)\{R(\Gamma)\}$ are K - Γ -protected, and each weak head reduces to itself, so by Lemma 20 the algorithmic derivation is free of singleton reduction. Therefore the desired derivation exists by Theorem 12.

4.4 Wrapping up

To complete the first half of the proof, we need only the fact that singleton erasure preserves derivability of judgements with mostly singleton free derivations.

Lemma 25

1. *If $\Gamma \vdash c_1 = c_2 : K$ has a derivation mostly free of singleton elimination, then $\Gamma^\circ \vdash_{sf} c_1^\circ = c_2^\circ : K^\circ$.*
2. *If $\Gamma \vdash c : K$ then $\Gamma^\circ \vdash_{sf} c^\circ : K^\circ$.*
3. *If $\Gamma \vdash K_1 \leq K_2$ then $K_1^\circ \equiv K_2^\circ$.*
4. *If $\Gamma \vdash \text{ok}$ then $\Gamma^\circ \vdash_{sf} \text{ok}$.*

Proof

By a straightforward induction on derivations.

Corollary 26 *If $\Gamma \vdash c_1 = c_2 : K$ then $\Gamma^\circ \vdash_{sf} (R(c_1, K)\{R(\Gamma)\})^\circ = (R(c_2, K)\{R(\Gamma)\})^\circ : K^\circ$.*

For the converse, we already have most of the facts we need at our disposal. We require two more lemmas. One states that the algorithm is symmetric and transitive. It is here that the use of a six-place algorithm is critical. For the six-place algorithm it is easy to show that symmetry and transitivity hold. For a four-place algorithm, on the other hand, it is a deep fact depending on soundness and completeness that symmetry and transitivity hold for well-formed instances, and for ill-formed instances it is not known to hold at all.

Lemma 27

1. *If $\Gamma_1 \vdash c_1 : K_1 \Leftrightarrow \Gamma_2 \vdash c_2 : K_2$ then $\Gamma_2 \vdash c_2 : K_2 \Leftrightarrow \Gamma_1 \vdash c_1 : K_1$.*

2. If $\Gamma_1 \vdash c_1 : K_1 \Leftrightarrow \Gamma_2 \vdash c_2 : K_2$ and $\Gamma_2 \vdash c_2 : K_2 \Leftrightarrow \Gamma_3 \vdash c_3 : K_3$ then $\Gamma_1 \vdash c_1 : K_1 \Leftrightarrow \Gamma_3 \vdash c_3 : K_3$.

Proof

By inspection.

The other lemma states that if singleton reduction is not employed in the algorithm, then whatever singleton kinds appear are not relevant and may be erased. Moreover, since the two halves of the algorithm operate independently (here again the six-place algorithm is critical), we may erase them from either half of the algorithm.

Lemma 28

1. If $\Gamma_1 \vdash c_1 : K_1 \Leftrightarrow \Gamma_2 \vdash c_2 : K_2$ without using singleton reduction, then $\Gamma_1 \vdash c_1 : K_1 \Leftrightarrow \Gamma_2^\circ \vdash c_2^\circ : K_2^\circ$
2. If $\Gamma_1 \vdash p_1 \uparrow K_1 \leftrightarrow \Gamma_2 \vdash p_2 \uparrow K_2$ without using singleton reduction, then $\Gamma_1 \vdash p_1 \uparrow K_1 \leftrightarrow \Gamma_2^\circ \vdash p_2^\circ \uparrow K_2^\circ$.

Proof

By induction on the algorithmic derivation.

It is worth noting that the algorithmic judgement in Lemma 28 is quite peculiar, in that Γ is ordinarily not equal to Γ° and K is ordinarily not equal to K° . Although there is a valid derivation of this algorithmic judgement, the soundness theorem does not apply, so it does not correspond to any derivation in the declarative system. When we apply this lemma below we will use transitivity to bring the assignments and kinds back into agreement before invoking soundness.

Lemma 29 If $\Gamma \vdash c_1 : K$, $\Gamma \vdash c_2 : K$, and $\Gamma^\circ \vdash_{sf} (R(c_1, K)\{R(\Gamma)\})^\circ = (R(c_2, K)\{R(\Gamma)\})^\circ : K^\circ$ then $\Gamma \vdash c_1 = c_2 : K$.

Proof

By Lemma 7, $\Gamma \vdash c_1 = R(c_1, K)\{R(\Gamma)\} : K$. By algorithmic completeness, $\Gamma \vdash c_1 : K \Leftrightarrow \Gamma \vdash R(c_1, K)\{R(\Gamma)\} : K$. By symmetry and transitivity of the algorithm, $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} : K \Leftrightarrow \Gamma \vdash R(c_1, K)\{R(\Gamma)\} : K$. Then, by Lemmas 23, 20, and 28, $\Gamma \vdash R(c_1, K)\{R(\Gamma)\} : K \Leftrightarrow \Gamma^\circ \vdash (R(c_1, K)\{R(\Gamma)\})^\circ : K^\circ$. By transitivity, $\Gamma \vdash c_1 : K \Leftrightarrow \Gamma^\circ \vdash (R(c_1, K)\{R(\Gamma)\})^\circ : K^\circ$. Similarly, $\Gamma \vdash c_2 : K \Leftrightarrow \Gamma^\circ \vdash (R(c_2, K)\{R(\Gamma)\})^\circ : K^\circ$.

Since the singleton-free system is a subsystem of the full system, we have by algorithmic completeness that $\Gamma^\circ \vdash (R(c_1, K)\{R(\Gamma)\})^\circ : K^\circ \Leftrightarrow \Gamma^\circ \vdash (R(c_2, K)\{R(\Gamma)\})^\circ : K^\circ$. Hence, by symmetry and transitivity, $\Gamma \vdash c_1 : K \Leftrightarrow \Gamma \vdash c_2 : K$. (Note that by applying transitivity, we have swept away the peculiarity noted above.) Therefore $\Gamma \vdash c_1 = c_2 : K$ by algorithmic soundness.

This completes the proof.

5 Related Work and Conclusions

The primary purpose of this work is to allow the reification of type equality information in a type-preserving compiler for a language like Standard ML, thereby eliminating the need to complicate the latter phases of the compiler with singleton kinds. Within this architecture, equality (or “sharing”) information would initially be expressed using singleton kinds, but at some point singleton kind elimination would be exploited to eliminate them.

An alternative approach for dealing with type equality is proposed by Shao and used in the FLINT compiler [12]. Shao's approach is formulated as a direct translation from a source-level module calculus to a singleton-free calculus without any use of singleton kinds. However, for purposes of comparison, Shao's approach may be seen as follows [11]: Equality specifications are taken as straight abbreviations and deleted from signatures. Then, in order to ensure that the desired subsignature relationships hold (recall the introduction), when a structure matching a signature with a deleted field is used in a context where that deleted field is required, the translation coerces the structure to reinsert the deleted field. Thus, Shao interprets the subsignature relation by coercion, whereas this paper's approach interprets it by inclusion, which may be more efficient. Shao's work also differs in that, since the meaning of Shao's modules are defined in terms of their translation, it has no analogue of the correctness theorem.

Aspinall [1] studies in detail a related type system with singleton types. The difference between singleton kinds and his singleton types is entirely cosmetic (this work could just as easily be presented as singleton type elimination), but various other technical differences between his system and this one make it unclear whether the same elimination process would apply to his system as well. Stone and Harper [15] compare this system to Aspinall's in greater detail.

An implementation of this paper's singleton kind elimination procedure in the context of the TILT compiler is planned, but has not yet been done. The main challenge we anticipate in this implementation, is that singleton kinds, in addition to expressing type equality information from the module language, are also very useful for expressing type information compactly. The elimination of singleton kinds could thus substantially increase the space taken up by type information. This issue could arise two ways; first, type information could take up more space in the compiler, resulting in slower compilation, and, second, if types are constructed and passed at run time [6], inefficient type representation could result in poor performance at run time. Shao *et al.* [13] discuss a number of ways to deal with the former issue, such as hashconsing and using explicit substitutions. The latter issue can be addressed by making the construction and passing of type information explicit [3] and doing so before performing singleton elimination; then singleton elimination will have no effect on the run-time version of type information.

A Inference Rules

Well-Formed Context

$$\boxed{\Gamma \vdash \text{ok}}$$

$$\frac{}{\epsilon \vdash \text{ok}} \quad (1)$$

$$\frac{\Gamma \vdash K \quad \alpha \notin \text{Dom}(\Gamma)}{\Gamma, \alpha : K \vdash \text{ok}} \quad (2)$$

Context Equivalence

$$\boxed{\vdash \Gamma_1 = \Gamma_2}$$

$$\frac{}{\vdash \epsilon = \epsilon} \quad (3)$$

$$\frac{\vdash \Gamma_1 = \Gamma_2 \quad \Gamma_1 \vdash K_1 = K_2 \quad \alpha \notin \text{Dom}(\Gamma_1)}{\vdash \Gamma_1, \alpha : K_1 = \Gamma_2, \alpha : K_2} \quad (4)$$

Well-Formed Kind

$$\boxed{\Gamma \vdash K}$$

$$\frac{\Gamma \vdash \text{ok}}{\Gamma \vdash T} \quad (5)$$

$$\frac{\Gamma \vdash c : T}{\Gamma \vdash S(c)} \quad (6)$$

$$\frac{\Gamma, \alpha : K' \vdash K''}{\Gamma \vdash \Pi \alpha : K'. K''} \quad (7)$$

$$\frac{\Gamma, \alpha : K' \vdash K''}{\Gamma \vdash \Sigma \alpha : K'. K''} \quad (8)$$

Subkinding

$$\boxed{\Gamma \vdash K \leq K'}$$

$$\frac{\Gamma \vdash c : T}{\Gamma \vdash S(c) \leq T} \quad (9)$$

$$\frac{\Gamma \vdash \text{ok}}{\Gamma \vdash T \leq T} \quad (10)$$

$$\frac{\Gamma \vdash c_1 = c_2 : T}{\Gamma \vdash S(c_1) \leq S(c_2)} \quad (11)$$

$$\frac{\Gamma \vdash \Pi \alpha : K'_1. K''_1 \quad \Gamma \vdash K'_2 \leq K'_1 \quad \Gamma, \alpha : K'_2 \vdash K''_1 \leq K''_2}{\Gamma \vdash \Pi \alpha : K'_1. K''_1 \leq \Pi \alpha : K'_2. K''_2} \quad (12)$$

$$\frac{\Gamma \vdash \Sigma \alpha : K'_2. K''_2 \quad \Gamma \vdash K'_1 \leq K'_2 \quad \Gamma, \alpha : K'_1 \vdash K''_1 \leq K''_2}{\Gamma \vdash \Sigma \alpha : K'_1. K''_1 \leq \Sigma \alpha : K'_2. K''_2} \quad (13)$$

Kind Equivalence

$$\boxed{\Gamma \vdash K_1 = K_2}$$

$$\frac{\Gamma \vdash \text{ok}}{\Gamma \vdash T = T} \quad (14)$$

$$\frac{\Gamma \vdash c_1 = c_2 : T}{\Gamma \vdash S(c_1) = S(c_2)} \quad (15)$$

$$\frac{\Gamma \vdash K'_2 = K'_1 \quad \Gamma, \alpha : K'_1 \vdash K''_1 = K''_2}{\Gamma \vdash \Pi \alpha : K'_1. K''_1 = \Pi \alpha : K'_2. K''_2} \quad (16)$$

$$\frac{\Gamma \vdash K'_1 = K'_2 \quad \Gamma, \alpha : K'_1 \vdash K''_1 = K''_2}{\Gamma \vdash \Sigma \alpha : K'_1. K''_1 = \Sigma \alpha : K'_2. K''_2} \quad (17)$$

Well-Formed Constructor

$$\boxed{\Gamma \vdash c : K}$$

$$\frac{\Gamma \vdash \text{ok}}{\Gamma \vdash b : T} \quad (18)$$

$$\frac{\Gamma \vdash \text{ok}}{\Gamma \vdash \alpha : \Gamma(\alpha)} \quad (19)$$

$$\frac{\Gamma, \alpha : K' \vdash c : K''}{\Gamma \vdash \lambda \alpha : K'. c : \Pi \alpha : K'. K''} \quad (20)$$

$$\frac{\Gamma \vdash c : \Pi \alpha : K'. K'' \quad \Gamma \vdash c' : K'}{\Gamma \vdash cc' : K'' \{c'/\alpha\}} \quad (21)$$

$$\frac{\Gamma \vdash c : \Sigma \alpha : K'. K''}{\Gamma \vdash \pi_1 c : K'} \quad (22)$$

$$\frac{\Gamma \vdash c : \Sigma \alpha : K'. K''}{\Gamma \vdash \pi_2 c : K'' \{\pi_1 c / \alpha\}} \quad (23)$$
