**SUBJECT: Contract No. DACA45-93-D-0027, Delivery Order No. 27, Mods 04
and 05; Draft Ellsworth AFB Multi-Phase Pilot Test Technology
Evaluation Report, BG-04 Site**

Dear Mr. Zaruba:

Enclosed are seven (7) copies of the draft Ellsworth AFB Multi Phase Pilot Test Technical Evaluation Report performed at the BG-04 site per instructions from Ms. Kellie Kachek of the Omaha District. I have forwarded two copies to Ms. Margaret Calvert at ACC CES/ESVW, Langley AFB, six copies to Mr. Dell Petersen at Ellsworth AFB, one copy to Peter Ismert at EPA Region VIII, one copy to Mr. Ron Holm at the State of South Dakota, two copies to Mr. Keith Anderson at RUST, and one copy to Mr. Robert Todd at EA.

If you have any questions regarding this deliverable please contact me at (916) 857-7281 or Mr. Bill BuChans at (423) 483-9870.

Sincerely,

Francis E. Slavich, PE
Program Manager

1.0 INTRODUCTION

In May 1996, Ellsworth Air Force Base (AFB), in Rapid City, South Dakota, and Radian Corporation (Radian) completed a seven-day pilot treatability test at the BG-04 site of Operable Unit-11 (OU) using Two-Phase Extraction (TPE), one of the Multi Phase Extraction (MPE) technologies. This report provides a summary of the methodology used during the test, the test results, and base-specific recommendations.

1.1 Purpose/Objectives

On 5 May 1995, Headquarters (HQ) Air Combat Command (ACC) published *United States Air Force Presumptive Remedy Engineering Evaluation/Cost Analysis* (PREECA) (U.S. Air Force [USAF], 1995) as a standardized decision framework specifying the criteria and associated decision logic necessary for implementing a nontime-critical removal action for various commonly used technologies. This decision framework, developed by Radian in conjunction with the U.S. Army Corps of Engineers and the USAF, combines the standard Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) nontime-critical removal action process with the concept of presumptive remedies and a "plug-in" logic tree approach. The result is a "generic" remedy selection document for all USAF installations that facilitates early and substantial risk reduction at USAF sites. **PREECA applies only to a closely defined subset of conditions** that the USAF has found to be common and that pose sufficient risk to justify nontime-critical removal actions. **This methodology was not intended to be used at sites where the need for cleanup actions is not readily apparent.**

In general PREECA focuses on remedies that can satisfy the majority of common USAF contamination situations, namely in situ bioventing, soil vapor extraction, groundwater containment, and capping. **However, PREECA is intended to be updated as new, successful remedies are established.** The USAF is

currently gathering extensive cost and performance data at a number of contaminated sites for addition of the multi-phase extraction technologies that include TPE, Low Vacuum Dual-Phase Extraction (LVDPE), and High Vacuum Dual-Phase Extraction (HVDPE). As part of this effort, HQ ACC has contracted with Radian through the Omaha District Corps of Engineers to evaluate the MPE technology for inclusion in the USAF PREECA. Radian, in conjunction with the USAF, developed an initial remedy profile for MPE as part of the PREECA effort.

This report presents the results of the TPE pilot test conducted at Ellsworth AFB in May 1996. It compares the pilot test results to the remedy profile for MPE technologies and demonstrates that TPE is an effective technology for use at Ellsworth AFB. In addition, it presents data on additional objectives for the pilot test, which were to:

- Demonstrate the contaminant removal effectiveness of the TPE technology;
- Determine the feasibility of installing a full-scale system;
- Collect sufficient engineering data to facilitate the design, installation, and operation of a full-scale extraction and treatment system; and
- Assist in the prevention of contaminant migration, thereby minimizing the threat of exposure to human health and the environment.

TPE was selected for testing at the BG-04 site because of the medium to low permeabilities of the soil at this site. The TPE technology is designed to enhance control of groundwater plumes in low- to moderate-permeability formations, as well as to remove contaminants from the saturated and vadose zones. Ellsworth AFB is in the process of implementing a time critical removal action at BG-04 that may consist of groundwater containment and/or

remediation. A large complement of information exists for the BG-04 site including the remedial investigation report [EA Engineering, Science, and Technology (EA), 1995] and the data from two recent studies (Rust Environmental and Infrastructure [RUST], 1995 and 1996).

1.2 Site Background

BG-04 is located in the northeastern portion of Ellsworth AFB as shown in Figure 1-1. This site is north of the housing area, and is in the vicinity of the site staging area used during the construction of the housing area. Previous field activities in the area have included installation and sampling of monitoring wells, water level measurements, aquifer testing, a seismic survey, and a direct push investigation. Data collected from these activities, in addition to data from this project, have been used to characterize the subsurface features and the nature and relative extent of contamination at the site.

1.2.1 Subsurface Features

The BG-04 site is underlain by approximately 18 to 20 feet of soil (alluvium) that overlies weathered shale and shale bedrock of the Pierre Shale Formation (Figure 1-2). The overlying soil consists of interbedded clay, silt, sand and gravel. The clay, silt, and sand units are fine grained and have low to moderate permeabilities based on visual inspection. The gravel units are present at the base of the site soils and represent higher permeability materials. These basal gravels are sometimes present in paleochannels eroded into the bedrock surface in the BG-04 site. Other contractors have postulated that contaminant migration occurs primarily down these paleochannels (RUST, 1995).

The upper portion of the Pierre Shale is weathered and consists of variably fractured light olive gray to dark olive gray clay, which increases in competence with depth. Weathered shale is at least 13 feet thick in the study area (work in the area of the BG-04 plume did not

delineate the depth at which competent shale is encountered). The permeability of the weathered and fractured shale is likely to be low.

Extraction well EW-2 was completed primarily within the overlying alluvium and a couple of feet into the weathered shale bedrock and was screened from 13 to 23 feet below ground surface (BGS). Depth to groundwater in the well was 14 feet BGS. The saturated alluvial thickness ranged from 4 to 6 feet in the extraction well and adjacent piezometers (P-1, P-2, and P-3).

Data from slug tests conducted by EA indicate the geometric mean hydraulic conductivity for the shallow aquifer at Ellsworth AFB is 1.1×10^{-4} centimeters per second (cm/s). Figure 1-3 shows the distribution of hydraulic conductivities for the saturated zone across the base. These slug tests were conducted on numerous wells in various parts of the Base. Most wells are screened across the entire saturated zone of the shallow aquifer. This aquifer is quite variable across the Base and consists of heterogeneous mixtures of alluvial material (clay, silt, sand, gravel) and/or fractured shale. This results in the rather large spread of hydraulic conductivities as shown in Figure 1-3.

Hydraulic conductivities were measured in the BG-04 test area by a slug test in EW-2 and a recovery test in P-1 and were 1.3×10^{-3} and 2.1×10^{-2} cm/s, respectively. These values, although variable, are consistent with the range of values measured elsewhere on the Base. This variability is indicative of the heterogeneous nature of the deposits at the site.

Groundwater flow direction is generally to the southeast in the BG-04 plume area; however, site-specific data were not yet available in the test area as of the preparation of this report.

1.2.2 Nature and Extent of Contamination

Figure 1-1. BG-04 Site, Ellsworth AFB

REV. 0

N:\612001\31\39\ELL A-A2.DWG

Figure 1-3. Histogram of Hydraulic Conductivities

Analysis of groundwater from monitoring well MW941148 (the closest existing monitoring well to the test area) showed the only organic contaminants detected were VOCs; metals were in a range consistent with acceptable background concentrations. Trichloroethylene (TCE) was the only contaminant (23 micrograms per liter [$\mu\text{g/L}$]) identified at this site.

The direct push investigation yielded 31 groundwater samples along and east of the base boundary. Most samples were analyzed by a mobile laboratory. The results revealed TCE in excess of 5 $\mu\text{g/L}$ at 13 locations. The highest TCE concentration was 1,068 $\mu\text{g/L}$ immediately north of water well ELN200 and about 600 feet east-northeast of MW941148. Other high concentrations (up to 227 $\mu\text{g/L}$) were detected north of MW941148 along the eastern base boundary in the vicinity of the site of this test.

Samples collected from EW-2 during this test indicated TCE concentrations of 36 to 45 $\mu\text{g/L}$.

2.0 TPE EXTRACTION TEST METHODOLOGY

The following information on the technical approach and the sampling and analytical methodologies is a summary of the *Ellsworth AFB OU-11, Vacuum Enhanced TPE Pilot Test Work Plan* (Radian, 1996). Additional details are contained in that document.

2.1 Test Procedures

The pilot-scale test of the TPE system consisted of a seven-day test conducted in the BG-04 plume on a new extraction well (EW-2) on the eastern base boundary. The test was completed 25 May 1996.

The locations of the test wells and monitoring points are shown in Figure 2-1. Well and piezometer characteristics are summarized in Table 2-1. Well logs are included in Appendix A.

2.1.1 Installation of Extraction Well and Piezometers

2.1.1.1 Extraction Well

The extraction well (EW-2) was installed in order to test TPE for the removal of TCE from groundwater from the BG-04 plume. The location was selected based upon limited data from previous direct push and seismic refraction data in the area. Well placement was planned to be within a bedrock paleochannel referred from the seismic refraction study in an area of elevated TCE concentrations.

The well was installed on 14 and 15 May 1996 using a hollow stem auger drilling rig with 10-inch outside diameter augers. Soil samples were collected continuously so that a lithologic log could be prepared (Appendix A). Samples were also collected for field headspace screening using a photoionization detector. The well was constructed with 4-inch diameter polyvinyl chloride (PVC) well casing and screen. The well casing, sand pack, and bentonite seal were

installed through the augers to ensure the stability of the well bore. The well screen was placed in the upper portion of weathered shale and across the entire saturated section of alluvial deposits. The 10-foot long screen was placed from 13 to 23 feet below ground surface (BGS) with an additional 10 feet of blank casing from 23 to 33 feet BGS. A lithologic log and completion detail are contained in Appendix A.

Data from soil samples collected from EW-2 and the adjacent piezometers indicate that, if present, the paleochannel is only 1 to 2 feet lower in elevation than the surrounding weathered Pierre Shale bedrock.

After the well was completed, it was developed to remove silt and clay and ensure communication with the aquifer. The well was first surged with a 4-inch, vented, surge block to loosen up the fine material from the sand pack so that it could be removed. The well was then purged using a disposable bailer and down-hole submersible pump. Water quality was monitored during development by visually observing the silt and clay content of the water and by pH and turbidity measurements. Development was judged complete when the pH was stable and turbidity of the water had decreased to the satisfaction of the supervising geologist. Development logs are contained in Appendix A.

Prior to beginning the TPE test, a simplified step test was run on 16 May 1996 to estimate the flow rate that could be expected from the well. EW-2 was pumped with a down-hole submersible pump at flow rates of approximately 1, 2, 4.5, and 9.6 gallons per minute (gpm). Each step was run for a few minutes until the water level in the well stabilized or the well pumped dry. During this short duration test, the well was able to sustain a rate of approximately 4.5 gpm with the water level at the base of the screen.

2.1.1.2 Piezometers

The piezometers (P-1, P-2, and P-3) were installed in order to monitor the response of the aquifer to the test. Piezometers were located at distances of 10, 25, and 50 feet from extraction well EW-2. The locations were chosen such that data could be collected on the response of the saturated and unsaturated (vadose) zones to TPE. Well screens were placed in the upper portion of weathered shale and across the entire saturated

Figure 2-1. BG-04, Test Well and Monitoring Points, Ellsworth AFB

Table 2-1

Summary of Wells and Monitoring Point Characteristics

Well/ Piezometer ID	Used to Monitor	Total Depth (ft BGS)	Screened Interval (ft BGS)	Approximate Distance from EW-2 (ft)
P-1	Water Level/Induced Vacuum	23	13-23	10
P-2	Water Level/Induced Vacuum	23	12-22	25
P-3	Water Level/Induced Vacuum	23	13-23	50
EW-2	Extraction Well	33	13-23	0
MW941148	Monitoring Well	22	11-21	500

BGS = Below Ground Surface

section of alluvial deposits. The screens also extended several feet up into the unsaturated zone. This type of completion allows both water level drawdown in the aquifer and induced air vacuum in the vadose zone to be measured in the same well. Figure 2-1 shows the locations of the well and piezometers.

The piezometers were installed on 15 May 1996 using a hollow stem auger drilling rig with 6-inch outside diameter augers. Soil samples were collected from selected intervals in P-2 and P-3 so that lithologic logs could be prepared and for headspace screening (Appendix A). Soil samples were not collected from P-1 due to its proximity (10 feet) to EW-2. The piezometers were constructed with 2-inch diameter (PVC) well casing and screen. The well casing, sand pack, and bentonite seal were installed through the augers to ensure the stability of the well bore. The details of the wells are contained in the completion logs in Appendix A. In general, 10-foot long screens were placed within the weathered Pierre Shale at a depth of 13 to 23 feet below the ground surface.

After the piezometers were completed, they were developed to remove silt and clay and ensure communication with the aquifer. The wells were first surged with a 2-inch, vented, surged block to loosen up the fine material from the sand pack so that it could be removed. The piezometers were then developed in the same manner as the extraction well. Development logs are contained in Appendix A.

2.1.2 Test Equipment

The test was conducted using a trailer-mounted, 25-horsepower, high-vacuum extraction unit capable of producing an air flow rate of 300 cubic feet per minute (acfm) at 25 inches mercury. The system is shown in schematic in Figure 2-2. Extracted groundwater was discharged to temporary storage tanks; extracted vapor was discharged to the atmosphere. The wastewater was transported and discharged to the OU-1 treatment plant. Procedures followed during the testing are summarized in the work plan described in Section 2.0.

2.2 Sampling and Analytical Methodologies

All sampling and analytical procedures (except where noted) were conducted in accordance with procedures and protocols described in the U.S. Environmental Protection Agency (EPA)-approved Ellsworth AFB Quality Assurance Project Plan. Sampling locations and frequency are summarized in Table 2-2.

2.2.1 Sampling Methodology

System parameters and ambient air conditions were measured with various vacuum gauges, meters, and thermometers included on the mobile trailer. Groundwater drawdown in the observation wells was measured using an electronic water level meter, and induced vacuum

OAK RIDGE, TENNESSEE

Figure 2-2. TPE System Schematic

was measured using Magnehelic[®] gauges. Data collected were recorded on field data tables (Appendix B).

Baseline groundwater samples from EW-2 were collected prior to TPE testing in 40-milliliter (mL) volatile organic analysis (VOA) vials using a dedicated Teflon[®] bailer. Prior to collecting the baseline samples, three well volumes of water were purged from the well. Approximately one hour after ending the test, post-test groundwater samples were collected using the dedicated bailer.

Water samples collected during the test were taken directly from the TPE trailer knock-out pot with VOA vials. All VOA vials were iced and stored in a dedicated cooler until shipped to Energy Laboratories, Inc., in Rapid City, South Dakota.

Vapor samples were collected using disposable syringes and evacuated vials provided by Microseeps Inc., Pittsburgh, Pennsylvania. Once the samples were collected, they were stored at ambient conditions until shipped to the Microseeps laboratory for analysis.

Quality control samples were also collected in the field. Duplicate water and vapor samples were collected at a 10% frequency by the methods previously described. Trip blanks accompanied the VOA vials throughout shipping and handling.

2.2.2 Analytical Methodology

Groundwater samples were analyzed for VOCs by EPA Method SW 8260. Soil vapor samples were analyzed for VOCs by Microseeps Analytical Method AM 4.03.

3.0 TEST RESULTS AND CONCLUSIONS

A critical step toward adding another presumptive remedy to the PREECA process is to compare that remedial technology's test results, referred to here as the "site-specific profile," to its PREECA remedy profile and determine the extent to which the two profiles match. The remedy profile comprises the performance data (including site selection criteria, process and methodology descriptions, and the acceptable range of quantitative results) by which the effectiveness of the presumptive remedy will be judged.

Radian performed a seven-day test on the EW-2 well at the BG-04 site. Table 3-1 summarizes the results achieved using the TPE system at the EW-2 well. The results of this test are described in Section 3.4.

Table 3-1
Summary of Results

System Parameter	EW-2
Groundwater Extraction Rate	2-3 gpm
Soil Vapor Extraction Rate	15-30 scfm
Contaminant Removal Rate	0.003 lb/day
Radius of Influence (Groundwater)	>70 ft

gpm = gallons per minute
scfm = standard cubic feet per minute

Based on the results of the pilot-scale TPE test conducted at Ellsworth AFB BG-04, Radian has constructed a site-specific profile for BG-04. A comparison of this site-specific profile to the general MPE profile and the specific TPE, LVDPE, and HVDPE profiles are presented in Tables 3-2 and 3-3. Note that the BG-04 profile falls within the general MPE profile and compares favorably with the corresponding TPE remedy profile.

3.1 System Operation

Physical and analytical data were analyzed to determine the following:

- Baseline VOC concentrations in groundwater;
- The major VOC constituents in the vapor and water streams;
- Average groundwater and soil vapor extraction rates;
- Average VOC extraction rates and total pounds of VOCs removed;
- The relationship between time and VOC concentrations;
- The relationship between time and vapor and water flow rates; and
- The relationship between distance and groundwater drawdown and induced vacuum, including radii of influence.

3.2 Radii of Influence and Production Rates

The following sections describe groundwater and vapor production rates and radii of influence.

3.2.1 Groundwater

The groundwater flow rate was measured using a totalizing flow water meter and is plotted along with the vapor flow rate on Figure 3-1. Water table drawdown was measured in piezometers P-1, P-2, and P-3 (Appendix B). A plot of drawdown vs time is presented in Figure 3-2. A plot of drawdown vs distance at the end of the BG-04 test is presented in Figure 3-3.

Table 3-2
MPE Technology Selection Criteria for BG-04

Criteria Parameter	BG-04 Site	Guideline
Contaminant	TCE	Halogenated VOCs, and non-halogenated VOCs and TPH for sites where expedited action is required
Contamination location	Saturated zone	Saturated zone alone or saturated and vadose zones combined
Contaminant concentration	36-45 µg/L	Significantly greater than MCLs MCL = 5.0 µg/L
Henry's Law Constant of majority of contaminants	0.297 at 20 C°	> 0.01 at 20 C° (dimensionless) ¹
Vapor pressure of majority of contaminants	58 mm Hg at 20 C°	> 1.0 mm Hg at 20 C°
Lithology of saturated zone	Clayey-gravel and weathered Pierre Shale	Sands to Clays
Natural groundwater production rate	Est. approximately 2 gpm	No limitations
Depth of contamination in vadose zone (if targeted)	N/A	> 5 feet BGS (MPE not applicable < 5 feet BGS)
Average air permeability of vadose zone (if targeted)	N/A	Low permeability (< 1 x 10 ⁻³) and moderate permeability (between 1 x 10 ⁻³ darcy and 0.1 darcy) soils.

¹ Dimensionless Henry's Law Constant in the form: (concentration in gas phase) / (concentration in liquid phase)

BGS = Below Ground Surface
 Hg = Mercury
 MCL = Maximum Contaminant Level
 mm = Millimeter
 MPE = Multi Phase Extraction
 N/A = Not applicable
 TCE = Trichlorethylene
 TPH = Total Petroleum Hydrocarbon
 VOC = Volatile Organic Compound

Table 3-3

LVDPE, HVDPE, and HVTPE Technology Selection Criteria for BG-04

Criteria Parameter	BG-04 Site	LVDPE Guideline	HVDPE Guideline	Guideline HVTPE
Groundwater production rate ¹	2.2 gpm (under vacuum)	> 2 gpm ²	no limitations	< 5 gpm
Depth of targeted contamination	> 18-23 feet BGS	no limitations	no limitations	up to 50 BGS ± (for groundwater production < 1 gpm) up to 20-30 BGS (for groundwater production = 5 gpm)
Lithology of saturated zone	clayey gravel and weathered shale	sands to silty sands	sandy silts to clays	sandy silts to clays
Average air permeability of vadose zone (if targeted)	N/A - not targeted	moderate permeability (between 1×10^{-3} darcy and 0.1 darcy)	low permeability (less than 1×10^{-3} darcy)	low permeability (less than 1×10^{-3} darcy)

¹ For MPE, the aquifer must be able to be dewatered.

² For flows < 2 gpm, pneumatic pumps may be used in place of submersible pumps

BGS = Below Ground Surface

gpm = Gallons per minute

N/A = Not applicable

Figure 3.1 BG-04 Vapor and Liquid Flow Rates

Figure 3.2 BG-04 Water Level Drawdown Over Time

Figure 3-3 BG-04 Drawdown Vs. Distance

During the BG-04 test, the groundwater flow rate surged at the beginning of the test due to evacuation of the well and sand pack, as well as from dewatering of the sand and gravel deposits near the well. After the initial surge, the water production rate fell slowly before stabilizing at approximately 2.2 gpm (Figure 3-1). The maximum radius of influence (defined as 0.1 feet of drawdown) is estimated to be approximately 70 feet based on the available data.

3.2.2 Vapor

The vapor flow rate was measured using rotameters located at the skid and is plotted along with the vapor flow rate on Figure 3-1. Induced vacuum was measured in piezometers P-1, P-2, and P-3 (Appendix B). A plot of the induced vacuum vs distance at the end of the BG-04 test is presented in Figure 3-4.

During the BG-04 test, vapor flow steadily increased during the first 80 hours of the test. During the latter portion of the test the flow rate stabilized at approximately 27 standard cubic feet per minutes (scfm). The increase in flow during the first 80 hours of the test occurred as the formation was dewatered and the relative permeability to vapor increased.

The radius of influence of the vapor is greater than 50 feet based on the available data. Significant vacuums were measured in the adjacent piezometers with values between 3.7 and 8.6 inches of water at the end of the test.

3.3 VOC Recovery

Table 3-4 summarizes analytical results for the VOCs detected in the samples collected during the test. TCE was the only contaminant found at the site (see Appendices C and D for the analytical laboratory results and chain-of-custody forms). Results of VOC sampling at EW-2 included:

- The baseline concentration (pre- test) of TCE in groundwater from EW-2 was 45 $\mu\text{g/L}$;
- The post-test concentration of TCE was 36 $\mu\text{g/L}$;
- The TCE concentration in the extracted water (collected from knock-out pot) averaged 2.4 $\mu\text{g/L}$. All samples contained less than the maximum contaminant level (MCL) of TCE (5.0 $\mu\text{g/L}$); and
- The TCE concentration in extracted vapor averaged 0.28 parts per million by volume (ppmv).

3.3.1 Extraction Results

Results of the BG-04 test included:

- Approximately 0.016 pounds of TCE was extracted from EW-2 in 162 hours of testing. The vast majority of the mass was extracted in the vapor phase.
- Average groundwater extraction rate was 2.4 gpm. Approximately 19,466 gallons of contaminated groundwater were extracted.
- Average vapor extraction rate from the formation was 20.7 scfm.
- The TPE extraction system transferred over 95% of the VOCs in the groundwater to the vapor phase, resulting in decreased concentrations in the water phase and reduced treatment cost.

3.3.2 VOC Removal Over Time

The graph showing VOC removal over time at the test well is provided in Figure 3-5. In general, steady concentrations in both extracted vapor and water were achieved after approximately 20 hours of testing.

Ninety-eight percent of the total VOCs removed were from the vapor phase and the remaining 2

percent were in the water phase. Much of this mass was stripped from the groundwater, but some was volatilized from the sediments as the formation dewatered.

3.3.3 Two Phase Extraction vs Pump and Treat Comparison

A comparison of mass removal rates over time was made between groundwater pump and treat and TPE. The comparison estimated pumping 19,466 gallons of groundwater (the volume removed during this test) with an average contaminant concentration of 40.5 µg/L of TCE (the average of the per- and post-test samples). The mass contained in this volume of water was compared to the measured mass extracted during the TPE test. This comparison shows that TPE would extract 2.4 times the amount of mass over pump and treat. These calculations are presented in Appendix E.

Figure 3-4 BG-04 Induced Vacuum Vs. Distance

3.4 Conclusions

3.4.1 Hydrogeologic Conclusions

A sustained flow rate of approximately 2.2 gpm and was generated during the TPE test. Most of the water production is believed to have been from moderately permeable saturated alluvium consisting of a heterogeneous mixture of clay, silt, sand, and gravel overlying weathered Pierre Shale bedrock. Hydraulic conductivities were measured in the BG-04 test area by a slug test in EW-2 and a recovery test in P-1 and were 1.3×10^{-3} and 2.1×10^{-2} centimeters per second (cm/s), respectively. This variability is consistent with the nature of the deposits at the site. These values are also consistent with hydraulic conductivities measured elsewhere on the Base, as shown in Figure 1-3.

Sustained flow rates from the TPE test (2.2 gpm) under a well head residual vacuum of 12 in of mercury were less than those achieved from the short duration step-rate pumping test (4.5 gpm). This is because the longer duration TPE test began dewatering portions of the saturated zone and the higher well yields could not be sustained. At a distance of 25 feet, the saturated thickness in P-2 decreased by approximately 25% during the test period.

A stabilized vapor flow rate of approximately 27 scfm was developed near the end of the TPE test. Flow was established through the more permeable gravel interval.

3.4.2 Technology Evaluation

The TPE test on well EW-2 at the BG-04 site demonstrated that TPE is effective in simultaneously removing volatile contaminants from both the vadose zone and groundwater in moderate-permeability formations. Although this site did not appear to have significant vadose zone contamination, the high vapor flow rate and high formation vacuums indicate that vadose zone removal would have occurred. The results support the existing remedy profile for

TPE because the site conditions fall within the bounds of the current TPE profile.

This site demonstrated a classical response to TPE. Groundwater flow rate declined early in the test and stabilized at 2-3 gpm as the formation dewatered. Vapor flow increased through the test and stabilized at 25-30 scfm as the subsurface dewatered and desiccated. Complete drawdown of the saturated zone into the Pierre Shale (23 feet) was obtained in EW-2.

Approximately 20,000 gallons of TCE-contaminated groundwater were removed during the seven-day test. This water was stripped by the process to below maximum contaminant levels (MCLs) without additional treatment. Approximately 98 percent of the TCE removed was in the vapor phase, indicating excellent stripping efficiency from the groundwater. Additional TCE was volatilized from the sediments as the formation dewatered. Both hydraulic and vacuum radii of influence were greater than 50 feet. Calculations indicate that TPE would likely result in a contaminant removal rate at least 2-3 times greater than could be obtained with traditional pump and treat at this site.

4.0 BASE-SPECIFIC RECOMMENDATIONS

Ellsworth AFB is planning a time-critical removal action to address the off-base plume at BG-04. The results of this test indicate that the TPE process could be effective in remediating this plume and controlling the further migration of the main plume off base.

Recent data collected by RUST indicate that the highest TCE concentrations in the off-base plume area are on the base fence line near EW-2 (22-44 micrograms per liter [ug/L]) and along the E-W road approximately 3,000 feet southeast of EW-2 (25-34 ug/L). Low concentrations have been detected further southeast (downgradient). It is possible that contamination has migrated rapidly along paleochannels eroded into the surface of the Pierre Shale.

A TPE system is probably the most aggressive technology available to contain and remediate this plume. It would likely result in an accelerated TCE cleanup rate over conventional technologies and remediate the site in the shortest possible time. To reach these goals, it is recommended that a TPE system be installed along the base boundary to prevent further off-base migration of the plume, effectively cutting off a continuing source. A second system installed along the E-W road would effectively isolate the highest concentration portion of the plume and prevent it from spreading while helping to remediate this portion of the plume in an accelerated time frame.

The stripping efficiency of the TPE process demonstrated at this site should allow the direct surface discharge of the extracted groundwater at concentrations below the MCL without the need for construction of a treatment plant or hauling of the water. This water could be discharged to stock ponds, such as the one located near the fence line, for beneficial reuse by local ranchers and farmers.

Length of Sandpack 12'
Depth of Well 25.11
Depth to Water 16.50 Depth to NAPL _____
Liquid Depth 8.61 x 0.16 = 1.4 (vol. of water in 2" PVC)
Liquid Depth 8.61 x 4.07 = 35.0 (vol. of water in 10" borehole)¹
Vol. of water in 10" borehole (35) - vol. of water in 2" PVC (1.4) = 33.6 (vol. of annular space)

Vol. of annular space (33.6) x 0.30 = (10.1) (vol. of water held in sandpack)

Vol. of water in sandpack (10.1) + vol. of water in 2" PVC (1.4) = (11.5) (one well volume)

Mr. Bill Buchans
Radian International
1093 Commerce Park Drive
Oak Ridge, TN 37830

Dear Mr. Buchans:

Attached is the final data listing for the samples we received on May 28, 1996, from James Machin, project #612-001-31-30.

Please give me call if you have questions or I can be of further assistance. Thank you for using MICROSEEPS.

Sincerely,

David J. Masdea

DJM/lsp

ANALYSIS OF VOLATILE ORGANICS IN GAS SAMPLES

Gas samples are received and secured in accordance with Microseeps documented sample receipt procedures. Analyses are performed using Microseeps Analytical Method AM4.03. Analytical method AM4.03 is a modification of USEPA Method 3810 (Headspace) and 8000 (Gas Chromatography). Modifications implemented are to accommodate the gas phase sample type only. All applicable quality control procedures are followed including continuing calibration check standards and laboratory blanks. Microseeps Analytical Method AM4.03 will be supplied upon request.

Mr. Bill Buchans
Radian International
1093 Commerce Park Drive
Oak Ridge, TN 37830

Dear Mr. Buchans:

Attached is the final data listing for the samples we received on May 29, 1996, from James Machin, project #612-001-31-30.

Please give me call if you have questions or I can be of further assistance. Thank you for using MICROSEEPS.

Sincerely,

David J. Masdea

DJM/lsp

ANALYSIS OF VOLATILE ORGANICS IN GAS SAMPLES

Gas samples are received and secured in accordance with Microseeps documented sample receipt procedures. Analyses are performed using Microseeps Analytical Method AM4.03. Analytical method AM4.03 is a modification of USEPA Method 3810 (Headspace) and 8000 (Gas Chromatography). Modifications implemented are to accommodate the gas phase sample type only. All applicable quality control procedures are followed including continuing calibration check standards and laboratory blanks. Microseeps Analytical Method AM4.03 will be supplied upon request.

APPENDIX E
Comparison of TPE vs Pump and Treat

SIGNATURE BILL BUCHAN'S DATE 25 JULY 96 CHECKED JLM DATE 7/25/96
 PROJECT PREECA - ELLSWORTH AFB JOB NO. 612 001 31 39
 SUBJECT PUMP & TREAT VS TPE SHEET 1 OF 1 SHEETS

COMPARISON OF TPE VERSUS GROUNDWATER PUMP & TREAT

TOTAL GALLONS REMOVED IN TEST = 19,466 GAL WATER.

AVERAGE CONTAMINANT CONCENTRATION IN WATER:

PRE-TEST = 45 mg/L
 POST-TEST = 36 mg/L FROM EW-2

$$(45 + 36) / 2 = 40.5 \text{ mg/L}$$

MASS CALCULATION:

$$\begin{aligned}
 &19,466 \text{ GALLONS } (8.34 \text{ LB/GAL}) (40.5 \text{ mg/L TCE}) (10^{-9} \text{ L/mg WATER}) \\
 &= 0.00656 \text{ LB TCE}
 \end{aligned}$$

COMPARISON OF MASS REMOVED WITH TPE TO MASS REMOVED WITH P & T:

$$\begin{aligned}
 &0.0159 / 0.00656 = 2.4 \text{ TIMES GREATER} \\
 &\text{WITH TPE.}
 \end{aligned}$$
