PREFACE

This document reports the results from an investigation of the availability of toxicology and risk assessment information in the scientific literature for chemicals detected in ambient air over Naval Air Facility, Atsugi, Japan. This work was sponsored by the Navy Environmental Health Center under Work Unit No. 63706N-M00095.004.#### and was performed under the direction of CAPT Kenneth R. Still, MSC, USN, Officer-in-Charge NHRC/TD.

The opinions contained herein are those of the authors and are not to be construed as official or reflecting the view of the Department of the Navy or the Naval Services at large.

EXECUTIVE SUMMARY

PROBLEM

Naval Air Facility, Atsugi, Japan, is located adjacent to a Japanese-owned facility in Kanagawa Prefecture used to incinerate garbage and other municipal waste. Prevailing winds distribute the incinerator plume across NAF Atsugi, on a frequent basis creating health concerns for American service members and their dependents. Two hundred thirty six (236) chemicals have been identified in the emissions; however, adequate toxicology information is not available for all compounds identified, making human health risk assessment efforts difficult.

OBJECTIVE

The objective of this study was to identify toxicology and human health risk assessment information on the chemicals identified from incinerator emissions over NAF Atsugi.

RESULTS

Of the 236 chemicals identified in the ambient air, there were 66 for which neither a Reference Dose (RfD) or Cancer Slope Factor (CSF) were identified and therefore have not been assigned a U.S. Environmental Protection Agency (USEPA) Risk-Based Screening Concentration (RBSC). Twenty-two compounds within this group of 66 have insufficient information at this time to derive an RfD or CSF and none of the 66 were found to have Minimum Risk Levels (MRLs) assigned by the Agency for Toxic Substances and Disease Registry (ATSDR). We also found insufficient information to suspect that any of the 66 compounds have carcinogenic properties. A second group of chemicals had been assigned either a CSF or an RfD, but not both. For these chemicals, the missing value was either found in or derived from toxicology data in the scientific literature. For both groups, alternative methodologies for developing exposure limits were utilized and include the Estimated Permissible Concentration (22 compounds) and Effects Screening Level approaches (39 compounds).

CONCLUSION

Although the data gap of toxicology information for use in human health risk assessment for chemicals identified at NAF Atsugi was large, risk assessment values were identified or derived. For many of the analytes, toxicology information is still absent; however, data identified within this study will assist in increasing the accuracy of the risk assessment effort.

ABSTRACT

The mission of Naval Air Facility Atsugi is to provide facilities, services and material support for U.S. Navy and Marine Corps aviation operations, and to provide logistic support for Carrier Air Wing FIVE. Approximately 8,000 military personnel and dependents are stationed at NAF Atsugi. A population boom in the early 1970s caused massive expansion in the communities surrounding the base and, as a result, the requirement for disposal of municipal and medical wastes also grew. Currently, the Shinkampo Incinerator immediately adjacent to NAF Atsugi burns over 180 tons of waste per day. Prevailing winds blow emissions from the incinerator stack over highly populated areas of NAF Atsugi. Under contract from the Navy Environmental Health Center, a private environmental consulting firm conducted an ambient air toxics study to evaluate the chemical constituency of the incinerator's emissions. This study examined the ambient air concentration of multiple toxics and criteria pollutants. Over 200 chemicals were identified in the air over NAF Atsugi; however, within the scientific literature, toxicology information suitable for use in human health risk assessment could be found for all but 66 of these chemicals. The present report describes the derivation of appropriate risk assessment reference values from data in the scientific literature and summarizes the health effects of each of the chemicals detected at NAF Atsugi.

KEY WORDS

Incinerator, pollutant, NAF Atsugi, emissions, ambient air

LIST OF ABBREVIATIONS

Note common chemical and measurement abbreviations are not included.

ATSDR	Agency for Toxic Substances and Disease Registry
CSF	Cancer Slope Factor
EPC	Estimated Permissible Concentration
ESL	Effects Screening Level
HEAST	Health Effects Assessment Summary Tables
IRIS	Instructional Resources Information System
MRL	Minimum Risk Level
NAF	Naval Air Facility
NEHC	Navy Environmental Health Center
NHRC/TD	Naval Health Research Center Detachment (Toxicology)
RBSC	Risk-Based Screening Concentration
RfC	Reference Concentration
RfD	Reference Dose

LIST OF TABLES

- Table 1. Chemicals detected at NAF, Atsugi that have no reported toxicity values—
Summarization of information from the literature to assist in deriving RfDs and CSFs
- Table 2. Estimated Permissible Concentration (EPCs) with available Effects Screening Levels
(ESLs) and RfDs and RfCs.

LIST OF APPENDICES

- Appendix 1. Oral toxicity values previously identified by ODU for chemicals at NAF Atsugi
- Appendix 2. Inhalation toxicity values previously identified by NEHC for chemicals at NAF Atsugi
- Appendix 3. Constituents for which no toxicity information was identified by NEHC in IRIS or HEAST

INTRODUCTION

The 1,249 acres of Naval Air Facility Atsugi lie in the Kanto plain on the main island of Japan, Honshu. The base was originally built in 1938 by the Japanese Imperial Navy but surrendered to American forces in 1945. It was formally commissioned on December 1, 1950 and was strategic throughout the Korean and Vietnam Wars. When USS MIDWAY was forward deployed at Yokosuka in 1972, Atsugi became a support base for her aircraft. The area surrounding Atsugi also experienced a population explosion during this same time frame. In 1991, the USS INDEPENDENCE replaced the MIDWAY field carrier landing practice was moved to the island of Iwo Jima. In August 1998, the USS KITTY HAWK replaced the USS INDEPENDENCE. Atsugi is encircled by the cities of Yamato, Ayase and Ebina and is home to approximately 8,000 personnel.

An increase in the population surrounding Atsugi resulted in a need to dispose of growing amounts of urban waste. As such, incineration is being used as a method of waste disposal. The Shinkampo Incinerator lies in a 15 m valley approximately 150 m from the perimeter of NAF Atsugi. Since the incinerator facility uses 30 m stacks for exhaust, high-rise housing units on the base sit in the direct path of the emissions plume when the incinerator is burning. Over 180 tons of material are burned each day, primarily at temperatures too low to destroy the majority of chemicals known to cause adverse health effects.

In order to provide exposure data for residents of NAF Atsugi, NEHC developed an ambient air toxics monitoring program which passively measured dioxins, acid gases, volatile organic compounds, semi-volatile organic compounds, Hg, particulate matter, heavy metals, pesticides and carbonyl. In addition, several criteria pollutant monitoring stations were set up to quantify levels of CO, SO₂, NO_x, O₃, PM₁₀, and PM_{2.5}. Both monitoring programs began in April 1998 and continued through June 1999. Over 200 chemicals were identified in the emissions

plume and ambient air; however, only 66 had neither a RfD nor a CSF. The goal of this project was to assemble adequate information to derive reference values or surrogate reference values for use in human health risk assessment of these 66 chemicals.

EXPERIMENTAL

As this project was aimed at compiling toxicology data on the chemicals of interest, no laboratory experimentation was conducted. However, literature searches included TOXLINE, Envirofacts, the National Institute for Environmental Health Sciences, the Texas Natural Resource Conservation Commission, and other worldwide web sites referenced within the text and tables. Book and journal holdings in several technical and medical libraries were also consulted.

RESULTS

In order to develop reference values for use in human health risk assessment of these 66 chemicals, our efforts focused on derivation of reference values where data from the literature was available. Appendices 1 and 2 summarize toxicity and risk assessment information assembled by Old Dominion University. Appendix 3 lists all chemicals for which the literature was found to be inadequate with respect to toxicity information and/or risk assessment reference values. Table 1 summarizes information from the literature on the chemicals detected at NAF Atsugi that have no reported toxicity values. Moreover, this table includes all information available in the literature and toxicology/risk assessment databases available over the worldwide web. Table 1 indicates that, for 27 of the 66 compounds, the literature provides no evidence of human carcinogenicity. In contrast, for 39 of the compounds, either no information was available on the carcinogenic potential or the carcinogenic potential of these chemicals is unknown. At this

time, there is insufficient information available to suspect that any of these compounds are carcinogens or that a cancer slope factor could be calculated.

Effects Screening Levels (ESLs) are currently used by the TNRCC Toxicology and Risk Assessment Section Staff to evaluate the potential for effects to occur as a result of exposure to concentrations of constituents in the air. They are based on data concerning health effects, odor nuisance potential, effects with respect to vegetation, or corrosion effects. If predicted or measured airborne levels of a constituent do not exceed the screening level, no adverse health or welfare effects would be expected to occur. If the airborne constituents exceed these levels a more in-depth review is indicated.

For Butane (106-97-8)

Short-term ESL (1 hr averaging period): 19,000 ug/m³
(8,000 ppb)

Long-term ESL: 1,900 ug/m³ (800 ppb)

Source: TOMES

Reprotex

- Butane reportedly has practically no toxic effects at concentrations below its flammability limits. Its major hazards are from Fire, Explosion, and Asphyxiation.
- No studies were found on the possible carcinogenic activity.
- Butane was not mutagenic in the Ames Salmonella/microsome test
- No reproductive studies were found for butane itself in humans or experimental animals.

Hazardtext - Hazard Management

- Exposure for 10 minutes to 10,000 ppm (1%) causes drowsiness.
- Exposure to moderate airborne concentrations dose not produce irritant effects
- Exposure of normal volunteers to concentrations of 1,000 ppm for 8 hours or to 500 ppm for 8 hours daily, 5 days/week did not produce any subjective or abnormal physiological effects.

Source: EPA/OTS Doc #86-90000054. Health effects assessment for butyraldehyde at the nitro plant (final report) with attachment and cover letter dated 122889 Abstract obtained on-line through National Library of Medicine (NLM)

Abstract summarizes published literature reports:

- Moderately to severely irritating to the eye and skin of rabbits
- LC50 values ranging from 2660 ppm in the guinea pig to 60,000 ppm in the rat [exposure duration not reported]
- Inhalation exposures of rats 6 hours/day for 12 days to 1000 ppm had no observable effects.
- Exposure (in rats) to concentrations ranging from 293 to 2710 mg/m³ for 6 hours/day, 5 days/week, for 4 weeks produced no effects at 930 mg/m³. At 2710 mg/m³ oral discharge and increased adrenal & lung weights were

		<p>observed.</p> <ul style="list-style-type: none"> • Reports observations from oral administration of 1.2 g/kg/day for 13 weeks in rats (irritation, inflammation and necrosis of gastric mucosa and forestomach). • In mice treated by gavage with 300 mg/kg/day and above, mild inflammatory lesions of the nasal cavity were observed; the no-effect level was estimated to be 75 mg/kg/day. • Mice administered a single dose of 30 mg/kg by intraperitoneal injection, or 300 mg/kg/day (author estimated dose) in drinking water for 50 days showed pathologic changes, including chromosomal and meiotic anomalies, in sperm at all stages of development. • Negative in Salmonella assay. In Chinese hamster ovary cells it did not induce chromosomal aberrations, but was positive in a sister chromatid exchange assay. Negative results were obtained in the sex-linked recessive lethal assay with Drosophila and sister chromatid exchange test with human lymphocytes. <hr/> <p>Source: EPA/OTS Doc #86-900000051 <u>Health effects assessment for butyraldehyde at the Decatur plant (final report) with attachments and cover letter dated 122889.</u> Abstract obtained on-line from NLM</p> <p>Human exposure to 230 ppm in air is non-irritating Covers same observations as noted in prior source (EPA/OTS Doc #86-900000054).</p> <hr/> <p>Source: EPA/OTS Doc #86-890000097 <u>Butyraldehyde: 9-day repeated vapor inhalation toxicity, vapor inhalation by dogs & rats for 12 & 13 wks, respectively & a 12-wk vapor inhalation study in rats with letter 020689</u></p> <p>Subchronic inhalation study in multiple mammals. No mention made of a NOAEL.</p> <p>I. <u>Guinea pigs, mice, rabbits, dogs, rats</u> Exposure: vapor concentrations of 0, 2000, 3100, and 6400 ppm 6 hour/day, 5 days/week, for 9 days over a 2-week period. Adverse Effects: mortality in the 6400 ppm group (all test species) decreased body weights at 3100 ppm and higher (gp,</p>
--	--	---

mice) and in all rats
decreased relative kidney weight (sprague-dawley rats) and liver weight (fischer 344 rats) in all exposure groups
hemorrhage of the ethmoturbinates in 1 sprague-dawley rat at 6400 ppm.

II. Sprague-Dawley rats (20/sex/group) & dogs (4 males)

Exposure: vapor concentrations of 0, 125, 500, and 2000 ppm
6 hour/day, 5 days/week, for 13 weeks

Adverse Effects: Mortality of 1 rat in the 2000 ppm group
Decreased alkaline phosphatase levels (rats, males, at 500 ppm)
Elevated mean albumin levels (125 ppm dogs)
Altered blood chemistry and decreased RBC and monocyte counts among 125 ppm and higher (rats)
Lesions of nasal epithelium and mild interstitial pneumonia at 125 ppm and higher (rats)
Nasal mucosal lesions at 500 ppm and higher (dogs)

III. Fischer rats (15/sex/group)

Exposure: vapor concentrations of 0, 1.0, 10.0, and 50.0 ppm
similar exposure

Adverse Effects: Increased relative kidney weights among high-dose males.

Source; ANON; Butyraldehyde. New Jersey Department of Health, Right to Know Program. (1996).

May enter the body when breathed in. Irritates or burns the skin, eyes and respiratory tract. May cause lung edema. May cause dizziness and lightheadedness. It is a flammable and reactive liquid and a fire and explosion hazard.

Folder also contains a list of prechronic studies for which toxicity technical reports were not prepared.

Short-term ESL: 14 ug/m³ (5 ppb)

Long-term ESL: 1.4 ug/m³ (0.5 ppb)

Source: Standard Report (TSCATS DATA)

Source lists several studies; selected abstracts follow:

1. Subchronic inhalation study. Rats exposed to 0, 1.0, 10.0, and 50.0 ppm for 6 hrs/day, 5 day/wk, for 12 weeks. Mortality was not observed. There were no compound-related clinical observations, body weight changes, hematology findings, or clinical biochemistry findings. There was a significant increase in the relative kidney weights of males exposed to 51.3 ppm. There were no compound-related gross necropsy or microscopic histopathological findings.

2 & 3. Mice & guinea pigs exposed to 0, 2000, 3100, and 6400 ppm for 6 hours/day, 5 days/wk for 9 days over a 2-wk period. Mortality was observed in all animals at 6400 ppm. Clinical observations included salivation in mice in the 3100 ppm group. Significant decreases in body weights were observed in the 3100 and 6400 ppm groups (mice and guinea pigs). Relative organ weight was not reported. There were no compound-related gross necropsy or histopathological findings.

4. Rabbits exposed to 0, 2000, 3100, and 6400 ppm for 6 hr/day, 5 days/wk, for 9 days over a 2-wk period. Mortality observed in all animals at 6400 ppm. Clinical observations included salivation, lacrimation and clear nasal discharge in animals in all exposure levels.

5. Subchronic inhalation toxicity. Dogs exposed to 0, 2000, 3100, and 6400 ppm for 6 hrs/day, 5 days/wk, for 9 days over a 2 wk period (1 animal/exposure level). Mortality observed in the 6400 ppm dog. Lacrimation, salivation, conjunctivitis, clear nasal discharge (6400 and 3100 ppm). Audible respiration (6400 and 3100 ppm).

Dogs exposed to 0, 125, 500, and 2000 ppm for 6 hrs/day, 5 days/wk, for 14 weeks. Mortality was not observed. Clinical observations included lacrimation, salivation and nasal discharge in all animals at all levels. Hematological and clinical biochemistry analysis revealed significantly higher mean albumin

		<p>levels in 500 and 125 ppm animals. Urinalysis, mean body weight and relative organ weight data revealed no compound-related findings. Gross necropsy revealed rhinitis marked with mucosal cell hyperplasia, inflammation, and squamous metaplasia (2000 ppm). Microscopic histopathological findings included hyperplasia of the goblet cells within the nasal mucosa (500 and 2000 ppm).</p>

Mutagenicity evaluation: rats exposed via inhalation to 0, 96.6, 307.2, or 1041.6 ppm for 6 hrs/day for 5 days. Significant increases in treated female rats relative to controls were observed in the frequency of numerical aberrations (low and mid-dose levels, no dose-related response observed). There were no significant differences observed between treated and control animals with respect to structural aberration frequency, and percentages of cells exhibiting one or more (or two or more) structural aberrations. <hr/> <p>Source: OPPT Chemical Fact Sheet prepared by Office of Pollution Prevention & Toxics U.S. EPA 1994 States the following:</p> <p>Breathing large amounts of cyclohexane for short periods of time adversely affects the human nervous system. Effects range from headaches to anesthesia, tremors, and convulsions. Contact with liquid or vapor can damage the eyes. Human health effects associated with breathing or otherwise consuming smaller amounts of cyclohexane over long periods of time are not known. [no exposure concentrations given]</p> <p>Information regarding carcinogenicity, developmental or reproductive effects either does not exist or is not adequate. Reports repeat exposure to large amounts in air causes nervous system effects, eye damage, and respiratory effects in animals. In workers exposed to atmospheric cyclohexane, 22.8% of</p>

the total respiratory intake was absorbed, and a "significant amount" of the absorbed cyclohexane was either retained or metabolized.

Acute Health Effects:

- Low acute toxicity, producing eye irritation in humans and neurological symptoms, other organ effects, and death in animals at very high doses.
- **Humans - detectable by odor and is irritating to the eyes at 300 ppm; ACGIH (1991) suggests 25 ppm as the odor threshold. Undiluted cyclohexane is irritating to the skin.**
- Animals - Oral LD50 in rats ranges from 8.0 to 39 ml/kg (both greater than 5 g/kg), depending upon the age of the animals. Oral LD50 for mice is 1.3 g/kg. Oral LD50 in rabbits is 5.5 - 6.0 g/kg; Dermal LD50 in rabbits is > 180 g/kg.
- **Exposure of rabbits to 3330 ppm produced no effect [duration not given]; 18,500 ppm for 8 hours was non-lethal; and 26,600 ppm for 1 hour was lethal. Application of 1.55 g/day to the skin for 2 days produced minimal irritation.**

Chronic Effects:

Administered subchronically, it is of low toxicity, producing neurological effects, ocular, gastrointestinal and respiratory effects in animals at very high, lethal concentrations

Humans: No information was found for the subchronic/chronic toxicity.

Animals:

- **No effects observed in rabbits exposed to 434 ppm for 50, 6-hour periods.**
- **No effects observed in rhesus monkeys exposed to 1234 ppm for 50, 6-hour periods.**
- Concentrations of 7445 ppm 6 to 8 hours/day for 2 to 26 weeks were lethal to rabbits, producing neurological effects as well as closure of the eyes, conjunctival infection, salivation, labored respiration, cyanosis and diarrhea prior to death.
- **Rats exposed by inhalation to 1500 or 2500 ppm for 9 to 10 hours/day, 5 days/week for 7, 14, or 30 weeks exhibited No adverse effects.**

Carcinogenicity: No information found

Genotoxicity: Negative for viral enhanced cell transformation in hamster embryo cells and for histidine reverse gene mutation in

Salmonella t.

Developmental/Reproductive Toxicity: No information found for humans or animals.

Neurotoxicity: CNS is a major target organ. High concentrations produce various effects ranging from trembling to death.

Humans: At high concentrations is a CNS depressant and may cause dizziness and unconsciousness.

Animals: Source gives various exposure levels and the observed effects. No NOELs given. Some of the observations are as follows:

Mice exposed to 50 mg/L (14,500 ppm) for 2 hours exhibited minimal narcotic effects; exposure to 18,000 ppm produced trembling within 6 minutes, disturbed equilibrium within 15 minutes, and complete recumbency within 30 minutes.

Concentrations of 7445 ppm, 6 to 8 hours/day, for 2 to 26 weeks were lethal to rabbits, producing convulsions, tremors, narcosis, and paresis of the legs.

Regulations, Standards, and Recommendations

Classified as a hazardous air pollutant in the Clean Air Act Amendments of 1990.

OSHA: PEL-TWA 300 ppm (1050 mg/m³)

NIOSH: 300 ppm recommended TWA

ACGIH TLV-TWA (1993-1994): 300 ppm

Source: Gupta KP; Mehrotra NK (1990). Mouse skin ornithine decarboxylase induction and tumor promotion by cyclohexane.

Chemical assessed for tumorigenic potential on mouse skin. Found effective as a stage II tumor promoter over mouse skin; possibly affects the biochemical events at the molecular level.

Source: Yasugi, et al. (1994) Exposure Monitoring and Health Effect Studies of Workers Occupationally Exposed to Cyclohexane Vapor.

Epidemiological study of 38 workers occupationally exposed (glue application activities). Geometric mean cyclohexane air level in the breathing zone was measured as 27 ppm with a maximum level of 274 ppm. Study identified existence of dose response relationships between levels in blood serum and urine. No significant differences seen between exposure groups and control for hematological or biochemical parameters or the incidence of sister chromatid exchanges in peripheral lymphocytes. Exposed subjects reported an increased incidence of dimmed vision and unusual smell.

REPROTEXT

Low acute toxicity: oral LD50 in rats of 29,820 mg/kg

In rabbits, a concentration of 3,300 ppm produced no visible effects; 12,600 caused lethargy, increased respiration rate, convulsions, and narcosis, and 26,600 ppm was lethal after 1 hour. A concentration of 18,000 ppm produced trembling, disturbed equilibrium, and recumbency in mice, rabbits and guinea pigs.

Effects of chronic exposure:

No effects on the peripheral nervous system were seen in a group of 18 workers exposed to 5 to 211 ppm for a median of 2.8 years.

A total of 50 repeated exposures to 1243 ppm for 6 hours produced no gross or microscopic abnormalities in a monkey. No nerve damage was seen in rats exposed to 2500 ppm for 9 to 10 hours/day, 5 to 6 days/week, for 7 to 30 weeks.

Microscopic changes in the liver and kidney were seen in rabbits exposed by inhalation to 786 ppm for 50 periods of 6 hours each.

Genetic effects: "It is possibly genotoxic in a limited number of short-term genetic tests, but negative in other test systems."

RTECS

Source gives several acute toxicity doses, some of which are:

LCLo: mouse, inhalation, 70 gm/m³/2H

LCLo: mouse, inhalation, 89600 mg/m³/1H

LC50: mammal, inhalation, 70 gm/m³

LD50: rat, oral, 12705 mg/kg

TCLo: rat, inhalation, 300 ppm/6H/2W intermittent

TCLo: rat, inhalation, 2000 ppm/13W intermittent

TCLo: rabbit, inhalation, 9220 ppm 6H/5W intermittent

TCLo: rabbit, inhalation, 7444 ppm/6H/2W intermittent

Standards & Regulations:

Lowest OELs:

OEL-Poland: TWA 80 mg/m³

OEL - Russia & Japan: TWA 150 ppm (520 mg/m³)

Others:

OEL - Australia, Austria, Belgium, Denmark, Finland, France, Germany, Sweden, Switzerland, The Netherlands, the Philippines, Turkey, UK, & the USA : TWA 300 ppm (1050 mg/m³)

HSDB

Microscopic changes occurred in liver & kidneys of rabbits exposed to 786 ppm for 50 periods of 6 hours. **No toxic changes were found in the tissues of rabbits after exposure for the same period to a concentration of 434 ppm.**

LOLI[®] Available

Source: DHHS - Occupational Health Guideline for Cyclohexane

The CNS depressant effect is from exposure to concentrations above 12,000 ppm; prolonged or repeated exposure to concentrations above 300 ppm produces a mild irritation of the eyes and upper respiratory tract.

Short-term ESL: 18,800 ug/m³ (10,000 ppb)
Long-term ESL: 1,880 ug/m³ (1,000 ppb)

Source: Standard Report (TSCATS DATA)

Source lists several studies; selected abstract follows:
1. Neurotoxicity evaluation. Rats exposed to 0, 4000, 8000, 16000, or 32000 ppm for 4 hours. Rats were hyperactive during the first hour at 4000 and 8000 ppm and the first half hour at 16000 ppm. All tests were passed (except for 1 vertical bar

failure at 4 hours) at 4000 ppm. Failures in grip, lift, and vertical bar were observed after exposure to 8000 ppm at all times after 1 hour, with ataxia after 2 hours. At 16000 ppm every rat failed grip, lift, bar and ataxia at 4 hours. At 2 hours after exposure to 32000 ppm all rats were failing most tests. Two animals died by 4 hours at 32000 ppm. Recovery from concentrations up to 16000 ppm took less than 1 hour; recovery at the 32000 level was slow and rats continued to fail grip, lift, bar, ataxia, pinna tactile reflex, and muscle tone at 18 hours post exposure.

**Source: Study Number: RACB84095
NTIS #PB86144979/AS**

Reproductive effects of ethanol were evaluated using CD-1 mice. Gives information regarding findings; no detailed dose-response data presented.

Source: Nelson, BK, et al. (1985). Teratological assessment of methanol and ethanol at high inhalation levels in rats.

Ethanol was administered by inhalation to rats at concentrations of 20,000 ppm, 10,000 ppm, 5,000 ppm & 0 ppm for 7 hr/day on days 1-19 of gestation. No definitive increases in malformations at any level of ethanol, although the incidence in the 20,000 ppm group was of borderline significance.

Source: Pastino et al. (1997). A comparison of physiologically based pharmacokinetic model predictions and experimental data for inhaled ethanol in male and female B6C3F1 mice, F344 rats, and humans.

Concentrations in study: 600 ppm for 6 hr; 200 ppm for 30 minutes; 50 ppm. Measured blood ethanol concentration (BEC) after exposure. Findings: inhalation of ethanol at or above the concentrations expected to occur upon refueling results in minimal BEC and are unlikely to result in toxicity.

TWA: 1000 ppm (1880 mg/m³)
STEL/C: -----
Irritation
A 4 - not classified as a human carcinogen

Source: TOMES
Hazardtext - Hazard Management
Generally reported lethal dose (oral route):
Adult 5-6 g/kg in the nontolerant adult
Pediatric - 3 g/kg

Source states that it is a confirmed human carcinogen (chronic ingestion of alcoholic beverages). IARC's Cancer Review: "human sufficient evidence"; "animal inadequate evidence"

Inhalation exposure: Human exposure to concentrations below 1000 ppm is considered safe for a working environment. Concentrations of 1000 to 5000 ppm produce some symptoms of irritation. Exposure at 5000 to 10,000 ppm has caused transient although strong irritation of the eye and nose as well as produced cough. At 15,000 ppm, effects were continuous lacrimation and cough. A level of 20,000 ppm was judged as barely tolerable. Above this level, the atmosphere was described as suffocating even for brief exposures.

Following an estimated ingestion of up to 60 mL, all but one out of 119 children (ages not specified) were asymptomatic. Slurred speech and ataxia developed in 2 out of 4 children who ingested an estimated 60 to 105 mL.

Reprotext System

Inhalation exposure at an airborne concentration of 14 to 28 mg/L over a 10 day period was sufficient to produce chemical dependence in rats; 1.4 mg/L for 1 to 2 weeks produced dependency in rats.

Ethanol itself is not mutagenic in the Ames test, but its metabolite, acetaldehyde, is mutagenic.

Ethanol can affect male fertility and produce reduced birth weight in newborns through paternal exposure, but is not known to be teratogenic through the father. **Men occupationally exposed to ethanol at airborne concentrations within recommended occupational exposure limits had normal sperm counts.**

Ethanol inhibited the production of testosterone when given to male rats at 1000 ppm; this effect may be due to its metabolite, acetaldehyde.

Source discussed consumption (mostly oral consumption) and resulting reproductive and carcinogenic effects (please see original source for further details).

HSDB

Various toxicity excerpts presented, quite a number dealing with ingestion and blood alcohol levels.

Item #6: Human volunteers exposed to alcohol vapor have observed at concentrations of 0.7 to 1% vapor the smell of alcohol was at first almost unbearable, although unpleasant later, and that the eyes began to burn with increased intensity after several minutes. **A vapor concentration of 0.25% had no notable effect on the eyes.**

Item # 28: Blood concentrations of 400 mg/dL or more produce dangerous or lethal depression of respiration; usually fatal.

		<p>Item # 55: The handling of motor vehicles was impaired by 100 mg/100 mL of alcohol in the blood, stupor might result from 300 mg/100 mL, and respiratory failure and sometimes death from 400 mg or more per 100 mL.</p> <p>Item # 56: Guinea pig: inhalation, no signs of intoxication: 6400 ppm, 8 hr; 3000 ppm 64X4hr</p> <p>Rat: inhalation, no signs of intoxication: 10750 ppm, 0.5 hr; 3260 ppm, 6 hr.</p> <p><u>Pharmacokinetics</u> (section of HSDB)</p> <ol style="list-style-type: none"> 1. Vaporized alcohol can be absorbed through the lung 3. The distribution of alcohol between alveolar air and blood depends on its speed of diffusion, and its vapor pressure at the prevailing temp & concentration of alcohol in the lung capillaries. Empirical determinations have yielded rather different values for this distribution ratio, but a commonly accepted value is 1:2100. <p>LOLI[®] available</p>

conducted or are not publicly available)
Safety & Risk Assessment: Lacking some of the data required for national assessment.

Scorecard, however, has an inhalation noncancer risk value (reference concentration) of 30 ug/m^3

Source: on-line, United Air Toxics website (UATW) under EPA/ Office of Air Quality Planning & Standards (OAQPS) Hydrogen Fluoride (and related compounds).

Document gives a hazard summary (acute, chronic, & reproductive/developmental effects). This substance has not been classified with respect to potential carcinogenicity by the EPA.

RfC & RfD are at present under review by the EPA.

LC50 Guinea Pigs $3,541 \text{ mg/m}^3$
LC50 monkeys $1,452 \text{ mg/m}^3$
LC50 rats $1,044 \text{ mg/m}^3$
LC50 rats 280 mg/m^3
(for HF 1 ppm = 0.82 mg/m^3)

ACGIH TLV, NIOSH REL, OSHA PEL, & MSHA standard - 2.5 mg/m^3

Source: Nordic Expert Group; Jahr, J. (1983) 41. Hydrogen fluoride.

Exposure to $2\text{-}3 \text{ mg/m}^3$ causes slight skin and eye irritation, for some, also nose irritation. Exposure to less than 1.7 mg/m^3 (air) has little or no effect on skin or mucous membranes. For the establishment of a hygienic standard, they recommend a sensation of mucous membrane irritation; if no such irritation occurs, they state that no other negative effects are likely.

Also talks briefly on fluorosis (long term exposure (years) may cause bone fluorsis -- no concentrations mentioned).

Source: Berge, et al. (1986). Concentration-time mortality response relationship of irritant and systemically acting vapours and gases.

A re-evaluation of the raw data of previously published acute inhalation toxicity studies of some volatile industrial chemicals. Attempting to obtain original.

Source: Dutch expert committee for occupational standards. (1989). Health-based recommended occupational exposure limits fro fluorine, hydrogen fluoride and inorganic fluoride compounds.

Volunteer study: HF at 2.1 mg/m³ in air --no local immediate effect
HF at 7.0 mg/m³ in air -- "discomfort"

Stated the estimated NAEL is 2,000 ppm (did not say if was strictly HF or fluorides in general)

Carcinogenicity: At present, the data do not suggest an increased risk of carcinogenicity

Source: National Institute for Public Health and Environmental Protection, the Netherlands; Report No 758474010 (1989). Integrated criteria document fluorides.

Insufficient data available to drive a recommended concentration for fluoride in the ambient air. **One study found effects on pulmonary function at concentrations of 98 ug/m and higher. Another study found gaseous fluorides up to a concentration of 16 ug/m³ had no measurable effect on the lung function of children.**

Source: Stavert et al. (1991). Relative acute toxicities of hydrogen fluoride, hydrogen chloride, and hydrogen bromide in nose and pseudo-mouth-breathing rats.

Inhalation exposure to 1300 ppm hydrogen fluoride for 30 minutes did not cause any deaths in nose breathing rats. In mouth breathing rats 25% mortality occurred. Other observations resulting from the exposure were presented (such as epithelial necrosis, submucosal necrosis).

Source: Meldrum (1993). Toxicology of substances in relation to major hazards -- Hydrogen fluoride.

Abstract -- suggests that the "Dangerous Toxic Load" for hydrogen fluoride, 12,000 ppm/min, be used in risk analysis.

Source contents are reported to contain toxicological data that is available on animals and humans; and observations from single exposure inhalation studies in animals. Details are not given. Attempts are being made to obtain the source.

Source: Lund et al. (1997). Exposure to hydrogen fluoride: An experimental study in humans of concentrations of fluoride in plasma, symptoms, and lung function.

The absorption of inhaled hydrogen fluoride was studied by measuring the concentrations of fluoride in plasma and in the breathing zone of 20 healthy nonsmoking men (ages 21 to 44 years) during exposure. Three exposure levels and symptoms discussed. Exposure was for one hour to constant HF

concentrations that ranged from 0.2 to 5.2 mg/m³ ; symptoms were only stated as “from the eyes and the upper and lower airways”. Did mention lung function (forced expiratory volume & Forced vital capacity), but no specifics given.
Recommendations to keep occupational HF concentrations well below 2.5 mg/m³ to avoid symptoms.

Source: Dalbey et al. (1998). Acute effects of 10-minute exposure to hydrogen fluoride in rats and derivation of a short-term exposure limit for humans.

A series of inhalation exposures in rats performed. From the resulting data, it is **predicted that an exposure level of 130 ppm for 10 minutes would not result in severe or irreversible health effects (for most individuals). Irritation is predicted to occur at this level; reversible effect.**

Source: Dalby et al. (1998). Short-term exposures of rats to airborne hydrogen fluoride.

Series of acute inhalation exposures: 2 or 10 minutes long; concentrations ranged from 135 to 8621 ppm. Three additional exposures at 20 to 48 ppm for 60 minutes performed. Observed changes were reported to be concentration related and more pronounced in the major airways near the point of entry.
Exposures of mouth breathing animals for 60 min to 20 or 48 ppm did not result in observable adverse effects.

TWA: ----
STEL/C: C 3 ppm
Irritation; burns; bone, teeth fluorosis
BEI

Source: DHHS-Occupational Health Guideline for Hydrogen Fluoride

NIOSH has recommended that the PEL be changed to 2.5 mg/m³ averaged over a work shift not to exceed 10 hours/day, 40 hours/week, with a ceiling level of 5 mg/m³ averaged over a 15 minute period.

Animals repeatedly exposed to 17 ppm showed damage to the lungs, liver, and kidneys, but at 8.6 ppm there was only occasional lung injury.

In human subjects, 120 ppm was the highest concentration that could be tolerated for 1 minute because of the onset of conjunctival and respiratory irritation with stinging of the skin. Repeated experimental human exposures to 2 ppm for 6 hours daily caused a slight stinging of the eyes and skin of the face, with

nasal irritation. Repeated exposures to low concentrations at work may produce chronic irritation of the nose, throat, and bronchi.

Source: TNRCC

** (3 hr)

Short-term ESL: 4.9 ug/m³ (3.5 ppb)

Long-term ESL: 0.5 ug/m³ (0.35 ppb)

The ** signifies that this constituent has "disaster potential". The "3 hr" for this constituent designates that the short-term ESL is averaged over 3 hours (instead of the usual 1), and the long-term ESL is for evaluation from the standpoint of effects on vegetation. This constituent is to be evaluated only for its contribution to total hydrogen fluoride.

Source: TOMES

RTECS

TDLo: man, oral, 143 mg/kg

LCLo: human, inhalation, 50 ppm/30M

LDLo: rat, intraperitoneal, 25 mg/kg

LC50: rat, inhalation, 1276 ppm/1H

LC50: guinea pig, inhalation, 4327 ppm/15M

LC50: monkey, inhalation, 1774 ppm/1H

Irritation: Eye -Standard Draize Test: Human, 50 mg; Severe Reaction

Reproductive effects:

TCLo: rat, inhalation, 470 ug/m³/4H; duration, 1-22 D of pregnancy (toxic effects: pre-implantation & post-implantation mortality)

TCLo: rat, inhalation, 4980 ug/m³/4H, 1-22 D of pregnancy (toxic effects: fetal death)

Standards & Regulations:

Various ones listed; a selected few follow:

Lowest

OEL - Denmark: TWA 2 ppm (1.6 mg/m³)

OEL - Hungary & Poland: TWA 0.5 mg/m³

OEL - Switzerland: TWA 1.8 ppm (1.5 mg/m³); STEL 3.6 ppm (3 mg/m³)

Others

OEL - Australia, Belgium, France, Germany, Japan, Russia, The Netherlands, The Philippines, Turkey, United Kingdom, OSHA:

TWA 3 ppm

Meditext - Medical Management

Death has occurred after ingestion of 1.5 g of HF (concentration unknown) within 6.5 hours of ingestion.

Estimates of the lowest lethal inhalation concentrations range from 50 to 250 ppm for 5 minute exposure and are based on accidental, voluntary and occupational exposure information.

Reprotext System

Repeated exposure to airborne concentrations of 3 ppm or less could be tolerated with no apparent ill effects for 6 hr/day for up to 50 days; redness of the skin and irritation and burning of the eyes and nose were noted at airborne concentrations between 3 ppm and 4.7 ppm. No significant changes in pulmonary function occurred with occupational exposure to airborne levels averaging 1.03 ppm.

HF has been reported to cause chromosome aberrations in bone marrow cells when inhaled by rats at an airborne concentration of 1 mg/m³ 6 hours daily for one month.

Chromosome aberrations in bone marrow cells of rats exposed to 1 mg/m³ (length of time not specified).

In female rats, concentrations of 0.1 or 0.2 mg/m³ increased preimplantation deaths and was embryotoxic and teratogenic at the higher dose, while no effects were observed at a concentration of 0.0025 mg/m³.

HSDB

Various human toxicity & non-human toxicity excerpts were given. A select few are presented below:

“Dose-effect relations: 3 ppm; good warning properties. MAC 8 hours, 10 ppm MAC 0.5 - 1 hour, 30 ppm sour taste smarting eyes, 60 ppm; burn pain may be delayed up to 1 hour. Apparent irritation of nose, and eyes, 120 ppm irritation of skin, respiratory; vapors can cause ulcers of respiratory tract 50 - 250 ppm dangerous with short exposure, 1500 ppm fatal to animals in tract, 5-minutes; concentration of 50-250 ppm can be dangerous even for brief exposures.”

Gas is potentially corrosive @ 20 ppm & can be tolerated for 1 min @ 120 ppm but is irritating.

Inhalation of the fumes of concentrated (60 to 100%) solution results in oropharyngeal irritation, coughing, and retro sternal burning. More severe exposures may produce laryngeal edema, bronchospasm, and pulmonary edema.

Guinea pigs and rabbits died within 5 min when they inhaled air containing 1500 mg/m³. All animals exposed to 500 mg/m³ for 15 min or more showed signs of weakness and ill-health; concentration below 100 mg/m³ could be tolerated for 5

		<p>hours without causing death.</p> <p>Rabbits & guinea pigs: at concentrations of not more than 50 mg/m³ HF induced coughing; inhaled in greater concentrations, respirations slowed and discharge from nose & eyes.</p> <p>Repeated inhalation of 17 ppm resulted in damage to the lungs, liver, and kidneys of animals, but similar inhalation of 8.6 ppm failed to elicit significant pathologic change in these tissues.</p> <p>Acute effects experienced by rabbits and guinea pigs exposed to concentrations of 24 - 8,000 mg/m³ for periods ranging from 41 hr to 5 minutes were presented. Evidence of eye and respiratory tract irritation was noticeable in all animals at all concentrations, although for those animals exposed at 50 and 24 mg/m³ for 5-15 minutes, signs were mild and not immediate. See original source for more details; no NOAELs found.</p> <p>Thirty day exposures of 5 lab species to levels that "bracketed the maximal and minimal effects....8.6 and 30 ppm in 6 hour, daily exposures." Exposure at the higher concentration was lethal to all the rats and mice, but not to guinea pigs, rabbits, and dogs. Among the surviving animals, the rabbits showed a slight reduction in body weight, the dogs were apparently unaffected, and the guinea pigs began to lose weight after the third week of exposure. Exposure at 8.6 ppm for 6 hr/day failed to alter significantly normal weight gains in any of the animals except rabbits.</p> <p>LOLI[®] available</p> <hr/> <p>Source: Standard Report (TSCATS DATA) Source lists several reports.</p>

Non-Human Toxicity Excerpts:

Liver damage & occasionally splenic & renal injury were found in rats exposed to 800-900 ppm for 6, 7-hr periods.

Severe hemorrhagic liver necrosis occurred in some rats; histologic changes in the kidneys consisted of focal necrosis resembling small infarcts. No changes in blood constituents or in the adrenals, pancreas, pituitary, ovaries, or testes were found. No specific NOAELs or dose response information presented in this source. (original reference is ACGIH, 1991)

Adult rabbits tolerated 1 g in a single, oral dose with no evidence of systemic toxicity.

Fatty livers and fatalities resulted when 1 g was injected sc in rats.

Rats subjected for 105 days to fumes in 0.6 & 0.15 mg/m³ did not show any hygienically significant changes; no evidence of toxicity was observed at 0.6 mg/m³. At 3 mg/m³, an increase in urinary sulfate index & cholinesterase activity & decrease in catalase activity. Hemodynamic changes were observed in viscera.

No local cutaneous or generalized systemic toxicity developed from painting the shaved skin of rats one to eight times with 0.1 mL of indene liquid. Guinea pigs were similarly unaffected by three applications of 0.5 mL of indene.

1,000 ppm for 8 hours or to 500 ppm for 8 hrs daily, 5 days/week did not produce any subjective or abnormal physiological effects.

Exposure to a 25% concentration each of isobutane, n-butane, n-pentane, and isopentane at concentrations ranging from 4 to 4,437 ppm 6 hrs daily, 5 days/week, for 3 weeks did not produce any nephrotoxicity in rats.

No deaths were observed in mice exposed to isobutane in concentrations of 350,000 ppm (35%)

Mice were lightly anesthetized after exposure to isobutane in concentrations of 150,000 to 230,000 ppm (15 to 23%). In dogs, inhalation exposure to concentrations of 450,000 ppm (45%) caused anesthesia.

A decreased myocardial threshold to the arrhythmogenic effects of injected epinephrine was seen in dogs and mice exposed to 50,000 ppm (5%) and 200,000 (20%), respectively. Serious ventricular arrhythmias were noted in dogs exposed to 150,000 to 900,000 ppm (15 to 90 %) concentrations of isobutane when epinephrine was injected.

In anesthetized monkeys, inhalation in concentrations of 50,000 to 100,000 ppm (5 to 10%) caused tachycardia, cardiac arrhythmias, a decreased cardiac output, and hypotension.

Subchronic exposure (90 days) to a consumer product containing 22 % isobutane caused no pathological effects in rabbits. Monkeys exposed for 90 days to 4,000 ppm of isobutane, or to an aerosol spray containing 65 % combined isobutane and propane also showed no pathological effects.

LC50 (inhl) mouse: 520,000 ppm for 2H.

Hazardous Substances Data Bank

Human Toxicity Excerpts:

1. Human volunteers, exposed to 2500 or 1000 ppm for 1 min to 8 hr and 500 ppm for 1 to 8 hr/day for 10 days showed no deleterious effects.
2. Toxicologically, the vapor exerts no effect on skin and eyes, except as a liquid in direct contact, where it produces chemical burns.
3. Exposure to isobutane (250, 500 or 1000 ppm) for periods of 1 min to 8 hr produced no untoward physiological effects as determined by methods which include serial EKGs & continuous monitoring of modified V5 by telemetry.
4. No untoward effects were observed in eight adults, males and females, exposed to 250 -1000 ppm in controlled-environment chamber for periods of 1 min, 2 min, 1 hr, 2 hr, & 8 hr. Also no untoward effects occurred after chronic exposures to 500 ppm.

Source also gives some non-human toxicity excerpts. Some

		<p>of which follow:</p> <p>In the mouse it is a CNS depressant at 15% in 60 min and at 23% in 26 min. At 22 to 27 % it is anesthetic in the mouse in 8.7 min. but caused respiratory arrest in 15 min.</p> <p>In the dog, anesthesia occurs at 45% in 10 min.</p> <p>Exposure of rats to a blend containing 25% each of n-butane, n-pentane, isobutane, and isopentane by inhalation at concentrations of 0, 44, 434, or 4437 ppm for 6 hr/day, 5 days/wk for 3 weeks found no clinical signs of toxicity; no gross or histopathological lesions; and no evidence of nephrotoxicity.</p> <p>Reprotext Chronic inhalation may produce liver and kidney damage.</p> <p>HazardText (R)- Hazard Management Isobutane is considered to be less toxic than n-butane. Reprotex

The toxicity of isopentane is thought to be similar to that of pentane; however, little is known about the toxicity of isopentane.

Inhalation of an airborne concentration of 500 ppm has been reported to produce no ill effects in humans (length of exposure was not given)

Isopentane was twice as toxic as pentane in acute inhalation exposures in mice.

Was not found to be mutagenic in the Ames Salmonella microsome assay.

RTECS

LCLo: mouse, inhalation, 419 gm/m³/2H (toxic effects: excitement)

TDLo: rat, oral 10 gm/kg/4W intermittent (toxic effects: weight loss or decreased weight gain; death)

The ability of isoprene to induce chromosomal aberrations in bone marrow and micronuclei in erythrocytes in bone marrow and in peripheral blood was evaluated in mice. Exposure: 438, 1750, 7000 ppm 6 hr/day for 12 exposures over 16 days. At all levels significant dose-related increases were seen in frequency of micronucleated polychromatic and normochromatic erythrocytes, but not of chromosomal aberrations.</p> <hr/> <p>Tice et al. (1988). <u>Chloroprene and isoprene: cytogenetic studies in mice.</u> Groups of male mice exposed to isoprene (438, 1750, & 7000 ppm) for 12 days. Exposure induced significant increases at all concentrations in the frequency of sister chromatid exchanges (SCE) in bone marrow cells and in the levels of micronucleated polychromatic erythrocytes (PCE) and of micronucleated</p>
--	--	--

normochromatic erythrocytes in peripheral blood. A significant lengthening of the bone marrow average generation time and a significant decrease in the percentage of circulating PCE was detected. Exposure did not induce in bone marrow a significant increase in the frequency of chromosomal aberrations nor did the exposure significantly alter the mitotic index. **The dose-response curves for SCE and micronuclei induction were non-linear, appearing to saturate at 438 and 1750 ppm, respectively. These results suggest that inhaled isoprene can be expected to induce tumors at multiple sites in mice.**

Source: Mast et al. (1990). Inhalation developmental toxicity of isoprene in mice and rats. (full-text on request).

Developmental toxicity was assessed in sprague-dawley rats & Swiss mice. Exposure to isoprene vapors: 0, 280, 1400, or 7000 ppm for 6 H/day, 7 days/wk, 6-17 days of gestation for mice and 6-19 for rats.

Findings: No significant effects upon body weights or reproductive indices at any exposure level in rats, nor was there a significant increase in the incidence of fetal malformations or variations. An exposure-correlated increase in the incidence of reduced vertebral ossifications (centra) in the 7000 ppm group suggests this level may be at or near a developmental toxicity threshold. Pregnant mice in the 7000 ppm group had a significant reduction in maternal body weight gain and uterine weight. Developmental toxicity was evident in mice as a reduction in fetal body weight which became statistically significant at 280 ppm for females and at 1400 ppm for males. There was a statistically significant increase in the incidence of supernumerary ribs in mice for the 7000 ppm group. Although there was **no** significant increase in the incidence of malformations, two fetuses with cleft palate were found, one in each of the two highest exposure groups. **The results indicate that 1400 ppm isoprene is a NOEL in the rat for both maternal and developmental toxicity. In mice, 1400 ppm is a maternal NOEL; however, a NOEL for developmental toxicity in the mouse cannot be assigned based on the results of this study.**

Author: Anonymous (1994). Isoprene ;IARC Monographs on the evaluation of the carcinogenic risk of chemicals to humans.

“Inadequate evidence in humans for the carcinogenicity of isoprene. There is sufficient evidence in experimental animals for the carcinogenicity of isoprene..Isoprene is possibly carcinogenic to humans.”

Source: on-line National Toxicology Program (1995). Toxicity studies of isoprene. Administered by inhalation to

F344/N rats and B6C3F1 mice.

Two week and 13-week inhalation studies. Exposures given & observations related to exposures.

NOAELs given:

1. 70 ppm for nonresponsive, macrocytic anemia; decreased hindlimb grip strength; olfactory epithelial degeneration; decreases in: epididymal weights, spermatid head counts, sperm concentration, and sperm motility.
2. 220 ppm for forestomach epithelial hyperplasia
3. 700 ppm for increased estrous cycle length
4. 2,200 ppm for testicular atrophy, sciatic nerve degeneration, and muscle atrophy.

A NOAEL was not achieved for spinal cord degeneration (less than 70 ppm) or developmental toxicity (less than 280 ppm).

Clear evidence of carcinogenicity.

Cox et al. (1996): Isoprene cancer risk and the time pattern of dose administration.

Inhalation study with mice exposed to up to 2,200 ppm isoprene for 4 to 8 hours per day for up to 80 weeks. Exposure to high concentrations of isoprene led to increased overall and site specific tumor risk. Among male mice, these sites included the lung, liver, forestomach, heart, and Harderian gland. The lowest observed effect levels were 70 and 140 ppm. The NOEL was 10 ppm. Lengthy exposure duration was not consistently associated with elevated tumor risks. Survival curves were not significantly altered by the doubling or quadrupling of exposure durations at low and high concentrations. However, at intermediate concentrations of isoprene, death rates were significantly affected by increasing the weeks of exposure. Although the cumulative dose remained the same, both tumor and mortality risks increased when the exposure duration was decreased with a proportional increase in the isoprene concentration. Tumor and mortality risks increased when exposure duration was reduced with a proportional increase in the daily exposure time. Thus, the cumulative dose was not considered a sufficient predictor of tumor risk. Tumor risk was not the product of the power of exposure concentration and other exposure factors. Tumor incidences at various sites were sometimes statistically related to each other. The authors concluded that isoprene risk assessment founded on equivalent dose metrics may offer misleading results; the development of more complex, biologically based models may be necessary to elucidate the dose time response relations of

isoprene.

Placke et al. (1996). Chronic inhalation oncogenicity study of isoprene in B6C3F1 mice.

The effects of exposure duration and concentration on the oncogenicity of chronically inhaled isoprene in mice were examined. Dose were mentioned as well as observed effects; however, no NOELs were given.

Male mice were exposed to up to 2200 ppm of nebulized isoprene for 4 or 8 hours per day, 5 days/week, for 20 to 80 weeks. Female mice were exposed to 0 to 70 ppm isoprene for 8 hours per day for 80 weeks. After 80 weeks of exposure, mice exposed to greater than 280 ppm had lower survival rates than mice exposed to less than 280 ppm. However, from the study, the authors concluded that despite clear, oncogenic threshold effect levels, tumor incidence is not adequately predicted by isoprene concentration, daily exposure duration, or exposure length.

Melnick et al. (1996). Inhalation toxicity and carcinogenicity of isoprene in rats and mice: Comparisons with 1,3-Butadiene.

No dose information given. Observations regarding findings such as cytogenetic effects, hematologic effects, etc. were given. Authors concluded that isoprene is a carcinogen in mice and a possible carcinogen in humans.

Source: on-line through National Toxicology Program: TR-486; Toxicology and Carcinogenesis Studies of Isoprene (CAS No. 78-79-5) in F344/N Rats (Inhalation Studies).

A two year study in which groups of 50 male & 50 female rats were exposed to 220, 700, or 7,000 ppm isoprene by inhalation, 6 hrs/day, 5 days/wk, for 104 weeks. Source describes pathologic findings. Authors conclude that there is **clear evidence of carcinogenic activity in males** (based on increased incidences of mammary gland neoplasms, renal tubule adenoma, and testicular adenoma); **some evidence of carcinogenic activity in females** (based on increased incidences and multiplicity of mammary gland fibroadenoma).

HSDB**

- **In human volunteers, the average odor perception occurred at 10 mg/m³ and at 160 mg/m³ they experienced slight irritation of the upper respiratory mucosa, larynx, and pharynx.**

	<ul style="list-style-type: none"> • The agent is possibly carcinogenic to humans. • At a concentration of 20000 ppm (2%) did not cause CNS depression in mice exposed for a 2 hr period. Deep CNS depression resulted from exposure to 35,000 to 40,000 ppm and death followed exposure to 50,000 ppm (5%). • In tests, isoprene was not found to be mutagenic • Inhalation exposure of rats & mice to 0, 438, 875, 1750, 3500, or 7000 ppm for 6 hr/day, 5 days/wk for 2 weeks had no effect on survival, body weight gain, clinical signs, hematological parameters or clinical chemical measurements and did not produce gross or microscopic lesions, however, male mice had reduced body weight gain, atrophy of the thymus and testis (7000 ppm only), olfactory epithelial degeneration (at 1750 or >), vacuolized liver cytoplasm and forestomach epithelial hyperplasia (at > or = to 438). The last effect was also seen in female mice. • Mice and rats were exposed to 0, 280, 1400, 7000 ppm for 6 hr/day, 7 days/week on days 6-17 (mice) or days 6-19 (rats) of gestation. In mice, exposure to 7000 ppm reduced maternal weight gain, and exposure to any dose reduced fetal body weight. An increase in the incidence of supernumerary ribs was observed at 7000 ppm, but there was no increase in fetal malformations. In rats, there was no adverse effect on the dams or on any reproductive index at any dose level, and there was no increase in the incidence of either fetal malformations or variations, other than reduced ossification of the vertebral centra at 7000 ppm. • Listed are various additional tests (e.g. toxicity, carcinogenic). No NOAELs. Please see original source. <p style="text-align: center;">Shepard's Catalog of Teratogenic Agents</p> <p>Mice & rats were exposed to doses of up to 7,000 ppm 6 hr/day during organogenesis. HSDB

Mice exposed at concentrations of 6600 to 13700 ppm demonstrated CNS depression in 30 -90 minutes and respiratory arrest at 16000 (1 of 4) to 32000 ppm (4 of 4) in 5 to 3 minutes, respectively. The CNS depressant concentration was 10000 ppm while a different study put the CNS depressant concentration at 8000 ppm and the fatal concentration at 13500 ppm.

Some effects of acute exposure to octane vapors on schedule controlled responding in the mouse are described [Glowa JR, Natale ME; Toxicol Pet Hydrocarbons, Proc Symp, 1st: 354-8 (1983)]. All that was said in HSDB was: "cumulative concentration effect curves were determined by comparing responding before and during exposure; concentration were incrementally increased at 40 min intervals until responding completely ceased. Octane did not generally decrease responding until concentration of approx. 1000 ppm was obtained; responding progressively decreased with increasing concentration up to 7000 ppm . The EC50 for octane was 2844 ppm.

Propane	74-98-6	<p>Source: on-line; Envirofacts, Chemical Reference: Scorecard.</p> <p><u>Human Health Hazard:</u> Suspected: Neurotoxicant</p> <p><u>Hazard Ranking:</u> Less hazardous than most chemicals in 1 ranking system.</p> <p><u>Basic Testing:</u> The following tests have either not been conducted or the information is not publicly available: Carcinogenicity; Chronic toxicity; Ecotoxicity.</p> <p><u>Safety & Risk Assessment:</u> data lacking</p> <hr/> <p>Source: ACGIH TLV/ BEI Booklet (1999) TWA: 2500 ppm STEL/C: ----- Asphyxiation</p> <hr/> <p>Source: TNRCC Short-term ESL: 18,000 ug/m³ (10,000 ppb) Long-term ESL: 1,800 ug/m³ (1000 ppb)</p> <hr/> <p>Source: TOMES</p> <p>RTECS OEL- Australia, Belgium, Hungary, The Netherlands, & the United Kingdom: Asphyxiant OEL- Denmark, Germany, Switzerland, The Philippines, & OSHA: TWA 1000 ppm (1800 mg/m³) OEL - Finland: TWA 800 ppm (1100 mg/m³)</p> <p>HSDB <u>Human Toxicity Excerpts:</u> Eight adult volunteers were exposed to isobutane, propane, or mixtures of the two gases (250-1000 ppm for 1, 5, & 10 min, & 1, 2, & 8 hr/day for 1 day or 2 wk) in a controlled chamber. No untoward subjective responses were reported during or following these exposures. No abnormal physiological responses were observed in any volunteer. Acute exposures to 250, 500, or 1000 ppm for periods of 1 min to 8 hr did not produce any untoward physiological effects. Propane when used as an aerosol propellant with isobutane in deodorant and antiperspirant products has not been shown to cause skin irritation in 125 human volunteers who applied the aerosol products twice daily for 12 wk.</p> <p><u>Non-Human Toxicity Excerpts:</u> Animal inhalation studies indicate a gas concentration of 89% to be below the anesthetic level but to depress the blood pressure of cats. Guinea pigs were exposed to 24000 - 29000 ppm and 47000</p>
---------	---------	---

	<p>- 55000 ppm for periods of 5, 30, 60, & 120 minutes. At the lower concentration irregular breathing was observed and at the higher concentration tremors were evident during the first 5 min of exposure. Stupor was commonly observed in the animals exposed for longer periods of time (up to 2 hr). All animals recovered from the exposure and there were no pathological signs of organ toxicity at necropsy. A CNS depressant effect was not seen until exposure levels were about 50000 ppm. [Other studies showed n-butane caused anesthesia in mice within 1 min at 22000 ppm and caused death in dogs at 20000 - 25000 ppm. Therefore, propane is much less toxic than n-butane.]</p> <p>In the primate, 10% induces some myocardial effects; at 20% aggravation of these parameters & respiratory depression.</p> <p>Subchronic inhalation studies have been conducted in which monkeys were exposed to approx. 750 ppm propane for 90 consecutive days with no toxicity or abnormalities observed. Similar inhalation studies conducted using monkeys except that the product tested was an aerosol spray deodorant containing a mixture of propane and isobutane in a concentration of 65% by wt. In these studies, all animals survived and showed no changes in behavior, body wt, hematology, blood chemistry, urinalysis, EKG, and pulmonary function. Gross microscopic exam revealed no evidence of organ toxicity.</p> <p>Propane was not mutagenic using the Ames Salmonella t. system.</p> <p>Inhalation represents the major route of systemic absorption. In human volunteers blood levels of propane could be detected after exposure to 250 - 1000 ppm.</p> <p>Hazardtext - Hazard Management</p> <p>Very little physiological reaction is produced by exposure to propane concentrations less than 1000 ppm</p> <p>Dizziness may occur after a few minutes of exposure to concentrations between 1 and 10 percent.</p> <p>Exposure to 100,000 ppm (10%) for a few minutes causes slight dizziness but not irritant effects.</p> <p>No adverse effects were observed in volunteers breathing 10,000 ppm (1%) for 10 minutes, but vertigo occurred when the concentration was increased to 100,000 ppm (10%) for 2 minutes.</p> <p>Volunteers who breathed concentrations of 1000 ppm, 8 hrs/day , 5 days one week and 4 days the following week had no EEG abnormalities or changes in adrenocortical, cardiopulmonary, neurological, cognitive, or visual functions.</p> <p>Dogs breathing 15 to 90 percent for 10 minutes had a decrease in the myocardial threshold to the arrhythmogenic effects of injected epinephrine.</p> <p>Decreased cardiac output was observed in dogs breathing</p>
--	--

		<p>10000 to 33000 ppm. Similar effects were shown in monkeys, who also developed respiratory depression at concentrations of 20000 ppm.</p> <p>LOLI[®] available</p>
2-Propanol	67-63-0	<p>Source: on-line; Envirofacts, Chemical Reference: <u>Scorecard Human Health Hazard:</u></p> <p>Suspected: Carcinogen, Cardiovascular or Blood Toxicant, Gastrointestinal or Liver Toxicant; Neurotoxicant; Respiratory Toxicant; Skin or Sense Organ Toxicant.</p> <p><u>Hazard Ranking:</u> More hazardous than most chemicals in 2 out of 10 ranking systems.</p> <p><u>Basic Tests:</u> Eight of the basic tests to identify chemical hazards have been conducted and are publicly available for this chemical (acute toxicity, chronic toxicity, neurotoxicity, developmental or reproductive toxicity, mutagenicity, carcinogenicity, ecotoxicity, environmental fate).</p> <p><u>Safety Assessment:</u> Lacks some of the national data required.</p> <p>Scorecard has Risk Assessment Data: RfC 2000 ug/m³ RfD 1.4 mg/kg-day</p> <hr/> <p>Source: TNRCC Short-term ESL: 7856 ug/m³ (3195 ppb) Long-term ESL: 785 ug/m³ (320 ppb)</p> <hr/> <p>Source: Standard Report (TSCATS DATA) Several studies listed; selected abstracts follow:</p> <ol style="list-style-type: none"> 1. Acute inhalation toxicity evaluated. Rats exposed to concentrated vapors (99%) for 2, 4, or 8 hours. Mortality was observed in 2/6 rats exposed for 4 hours and in all 6 exposed for 6 hours. An LD50 value was not reported; clinical observations and necropsy evaluations were not reported. 2. Subchronic Toxicity. Rats exposed via inhalation to 0, 1000, 5000, 10000, and 15000 ppm for 9 days over a 12-day period [length of exposure not specified]. Incidence of mortality and clinical sign of toxicity during exposure were not reported. Hyaline droplet nephropathy was observed in animals in 4/5 and 5/5 males in the 1000 and 5000 ppm groups respectively. <hr/> <p>Source: on-line; National Toxicology Program <u>Genetic Toxicology:</u> Salmonella - negative <u>Toxicity:</u> Source contains 25 total of various TDLo,</p>

TWA: 200 ppm; STEL/C: 400 ppm; A 4 - not classifiable as a human carcinogen)

Source: DHHS - Occupational Health Guideline for Isopropyl Alcohol

The most important toxic effect is narcosis, which occurs in mice at vapor concentrations of 3000 ppm, the effects increasing with the duration of exposure. Exposure to higher concentrations results in ataxia followed by deep narcosis and death.

Human volunteers reported mild irritation of the eyes, nose, and throat after 3 to 5 minutes exposure to vapor at 400 ppm; at 800 ppm the results were not severe, but most subjects found the atmosphere to be objectionable.

No chronic systemic effects have been reported in humans.

Source: Ohashi et al. (1987). Acute effects of isopropyl alcohol exposure on the middle ear mucosa.

Guinea-pigs were exposed to 0, 400 ppm, or 5500 ppm isopropyl alcohol vapors for 24 hours. Specific details given regarding findings (e.g. ciliary activity, mucosa deterioration, cytoplasmic protuberances and vacuolation of epithelial cells and number of goblet cells). It was concluded that a level of 400 ppm causes no significant middle ear disorders, but recommends extensive regular otolaryngeal examinations to workers exposed to higher levels.

Source: Ohashi et al. (1988). Toxicity of isopropyl alcohol exposure on the nasal mucociliary system in the guinea pig.

Guinea-pigs were exposed to 0, 394, or 5440 ppm isopropanol vapor for 24 hours. They were examined for ciliary activity and ultrastructural changes. A synopsis of findings was given. It was concluded that exposure to 400 ppm damages nasal mucosa but recovery occurs within 2 weeks. Exposure to 5500 ppm causes damage that requires more than 2 weeks to recover.

Source: EPA/OTS; Doc #86-920000729. A single generation reproduction and embryotoxicity study with isopropyl alcohol in rats (final report) with attachments and cover letter dated

013092.

Isopropanol was orally administered in doses of 0, 0.5, 1.0, and 2.0% to male and female rats. Treatment length and findings presented (e.g. decreases in food and water intake and body weight; increases in kidney and liver weights; decreases in pup weight gain and survival). **The NOEL for reproductive effects from this study was 1.0%.**

Source: Anonymous. (1993). CEC. The toxicology of chemicals. 2. reproductive toxicity; 1 (EUR 14991).

States:

Insufficient data to evaluate the effects on endocrine functions, gonadal effects and fertility in male and female animals.

One study in the rat indicates no specific risk of inhalation exposure for the developing organism.

No data on reproductive toxicity are available for humans.

Source: Bates et al. (1994). Developmental neurotoxicity evaluation of orally administered isopropanol in rats.

Pregnant rats were treated with 200, 700, or 1200 mg/kg isopropanol by daily gavage in bolus doses from gestation day six through postnatal day two. No exposure related clinical signs were observed in the dams or their offspring. No dose related effects were observed for: maternal or pup body weight gain; pup sex ratio; pup developmental landmarks; pup survival; motor activity; learning and memory performance; maternal organ weights; or the weights of four regions of the brain in the pups.

Source: Bevan et al. (1995). Two-generation reproduction toxicity study with isopropanol in rats.

Rats (P1) were orally dosed once daily with 0, 100, 500, or 1000 mg isopropanol kg⁻¹ for at least 10 weeks prior to mating. Parental animals were mated within groups for up to 3 weeks. Parental females were dosed during mating, gestation and lactation; parental males were dosed during mating through delivery of their last litter sired. The P2 adults were selected from the litter and were dosed for 10-13 weeks before mating to produce a single litter. [The latter dosage was not specified] **The NOEL for reproductive effects in this study, based on the reduced male mating index of the high-dose P2 males, is 500 mg kg⁻¹day⁻¹.**

Source: Gill et al. (1995). Isopropanol: Acute vapor

inhalation neurotoxicity study in rats.

Males & Female rats were exposed for 6 hours to isopropanol vapor at 0, 500, 1500, 5000, or 10000 ppm. Behavioral observations were made. Exposure caused a spectrum of transient effects, among which were: narcosis at 10000 ppm; sedation at 5000 ppm; and minor decreases in motor activity in males at 1500 ppm. **The NOEL for neuro effects was 500 ppm.**

Source: Kapp et al. (1996). Isopropanol: Summary of TSCA test rule studies and relevance to hazard identification.

In general, the data showed that IPA has a low order of acute and chronic toxicity; dose not produce adverse effects on reproduction; is neither a teratogen, a selective developmental toxicant, nor a developmental neurotoxicant; and is not genotoxic or an animal carcinogen. However, it is a potential hazard for transient CNS depression at high exposure levels. It produced effects to several rodent toxicity endpoints at high dose levels (i.e. motor activity, male mating index, and exacerbated renal disease) which are of unclear relevance to human health. The data confirm that in mammalian biological systems, isopropanol produces a significant narcotic effect upon exposure at high levels for extended periods of time, with no irreversible effects even after repeated exposure. **Overall, these studies demonstrate that exposure is a low potential hazard to human health.**

Source: Burleigh-Flayer et al. (1997). Isopropanol vapor inhalation oncogenicity study in Fischer 344 rats and CD-1 mice.

The carcinogenic potential of isopropanol vapor was studied. Exposure concentrations & dosage: 500, 2500, 5000 ppm vapor for 6 hours/day, 5 days/wk for up to 78 and 104 wk. Findings discussed included deaths, organ weights, renal tubular proteinosis & dilation, and lesions associated with chronic kidney disease. Mentioned was the transient manifestation of narcosis at 2500 or 5000 ppm observed in all animals. The only neoplastic lesion showing an increased incidence was Leydig cell adenomas; this was not considered to be treatment related because of its occurrence in control rats. **It was concluded that chronic renal disease was the major cause of death of male rats exposed to 5000 ppm. The NOEL for isopropanol toxicity in both rats and mice is estimated to be 500 ppm; the NOEL for carcinogenicity is greater than 5000 ppm.**

Source: Burleigh-Flayer et al. (1994). Isopropanol 13-Week inhalation study in rats and mice with neurotoxicity

evaluation in rats.

Study to evaluate the possible subchronic toxicity as well as neurobehavioral effects. Exposure of rats & mice to concentrations of 0, 100, 500, 1500, or 5000 ppm for 6 hr/day, 5 days/wk for 13 weeks.

Narcotic effects were noted only during exposures at 1500 and 5000 ppm; signs were typically noted during exposures only (were absent following exposures).

The only clinical signs observed included swollen periocular tissue, perinasal encrustation, and ataxia for rats of the 5000 ppm group. Increased motor activity for female rats in the 5000 ppm groups was noted at weeks 9 and 13. Decreases in body weight and body weight gain were observed for rats of the 5000 ppm group at the end of the first week of exposure. During the remaining weeks, increases in body weight and/or body weight gain were observed for rats of the 1500 and 5000 ppm group. No exposure related effects on body weight were noted for male mice; however, increased body weight and body weight gain were noted for female mice of the 5000 ppm group.

The only organ weight effect noted was an increased relative liver weight in both sexes of rats and female mice of the 5000 ppm group. No gross lesions determined to be exposure related at necropsy. The only microscopic change observed was hyaline droplets within the kidneys of all male rats (including controls). The size and frequency of the hyaline droplets were increased for the exposure groups compared to the control group. These differences were not clearly concentration related, although this microscopic change was most pronounced in the high-concentration group.

Sum: toxic effects produced only at the highest concentration and a kidney change in male rats of unknown biological significance.

Source: TOMES

Workers exposed for 8 hours to airborne concentrations of 470 - 493 mg/m³ had blood isopropanol concentrations below the limits of detection (0.001 g/dL) & blood acetone concentrations of 0.004 to 0.016 g/dL

RTECS

Lists Acute Toxicity information (e.g. many TDLo, LDLo, etc.) some of which may be found above under the National Toxicology Program.

Also lists 19 OELs, the highlights of which are:

The lowest:

- OEL - Turkey: TWA 200 ppm (500 mg/m³) Jan 1993
- OEL - Denmark: TWA 200 ppm (490 mg/m³); Skin Jan 1993
- OEL - Sweden: TWA 150 ppm (350 mg/m³); STEL 250 ppm (600 mg/m³) Jan 1993

Others:

OEL - Australia, Belgium, and the United Kingdom all have a TWA of 400 ppm and a STEL 500 ppm Jan 1993

OEL - France, Germany, Japan, Russia, Netherlands, Philippines, and US have a TWA of 400 ppm and no STEL specified.

Reprotex System

Ingestion of as little as 100 mL may cause death.

Irritation and mild CNS depression are caused by inhalation exposure at airborne concentrations up to 800 ppm

- **The No Effect Level with inhalation exposure has been reported to be 200 ppm /8 hours.**
- As little as 0.5 mg/kg may cause symptoms, but adults have survived oral doses as high as 1 liter.
- **Inhalation exposure to airborne concentrations up to 400 ppm has caused mild eye, nose, and throat irritation, while inhalation of 800 ppm produced more intense signs and symptoms (these were not specified)**
- In rats exposed by inhalation, acute neurotoxicity was noted at 1 and 6 hours at 5000 ppm , but only minimal effects were seen at 1500 ppm and the animals recovered within 5 hours. **No toxicity was noted at 500 ppm.**
- Daily ingestion of doses as high as 6.4 mg/kg for 6 weeks produced no apparent ill effects in human volunteers.
- It is not regarded as a human carcinogen
- It has not been genotoxic in a variety of short-term tests
- A Russian study in 1978 in which rats were given 0.18 mg/kg/day orally for 6 months reported decreased fertility; the offspring of pregnant rats given 0.018 to 1008 mg/kg had embryotoxicity and birth defects. The no-effect level in the latter study was 0.015 mg/kg.
- It is reported by Kapp et al, 1996) that isopropanol was neither a reproductive toxin nor a teratogen in extensive animal testing.
- A two-generation study in rats and neurodevelopmental toxicity studies in rats and rabbits exposed to as much as 1200 mg/kg/day found no adverse effects.

HSDB

Lists human toxicity excerpts, some of which are repeats of those mentioned previously.

- Probably lethal oral dose for adult is 8 oz (240 mL), but as little as 20 mL in water can produce symptoms.
- 400 ppm is considered to be low enough not to cause CNS depression, although slight irritation may occur.

		<p>Several non-human toxicity excerpts were presented, the most noteworthy one for our purposes appeared to be the following:</p> <p>Rats exposed continuously for 86 days to air concentration of 8.14 ppm (20 mg/m³) showed changes in reflex behavior and increased retention of bromosulfophthalein. Post mortem findings include enlarged spleen, some evidence of liver parenchymal cell dystrophy & degenerative changes in cerebral motor cortex.</p> <p>ReproTox System</p> <p>Recent teratologic evaluation in rats indicate that this compound only produced adverse developmental effects at inhalation exposures that were maternally toxic. The congenital abnormalities observed were limited to skeletal malformations.</p> <p>Two-generation rat studies only showed 1000 mg/kg/d treatments to have adverse effects on successful matings in first generation males. There was also an increase in postnatal mortality in this generation. No adverse effects were reported at the next lower dose, 500 mg/kg/d.</p> <p>A rat and rabbit developmental toxicity study showed no teratogenic effects at doses that were clearly maternally toxic. In a separate rat study, no evidence of developmental neurotoxicity was associated with gestational exposures to isopropanol as high as 1200 mg/kg/d.</p> <p>Shepard's Catalog of Teratogenic Agents</p> <p>Rats exposed for 7 hours daily on day 1-19 to 10000, 7000, or 3500 ppm. At 3500 ppm no adverse fetal effects were found while at the higher doses malformations, resorptions, and fetal deaths were increased. Skeletal defects were the main defects.</p> <p>LOLI[®] available</p>

Source: on-line; United Air Toxics Website

Hazard Summary:

- Limited information is available on the health effects.
- No information is available on the acute effects in humans.
- Animal studies have reported that exposure to high levels of propionaldehyde, via inhalation, results in anesthesia and

		<p>liver damage, and intraperitoneal exposure results in increased blood pressure. Acute animal tests such as the LC50 and LD50, in rats and mice, have shown it to have moderate acute toxicity from inhalation, oral, and dermal exposures.</p> <ul style="list-style-type: none"> • No information is available on the chronic effects in animals or humans. • The RfD has not been established. • The RfC is under review by EPA. • No information is available on the reproductive/developmental or carcinogenic effects in animals or humans. EPA has not classified propionaldehyde for carcinogenicity. <hr/> <p>Source: Anonymous (1997). <u>Propionaldehyde</u>. (From Beratergremium fuer umweltrelevante Altstoffe (BUA).</p> <ul style="list-style-type: none"> • Values for acute oral toxicity (LD50) lie between 800 and 3300 mg/kg for the rat. • Dermal LD50 for the rabbit lies between 2500 and 4047 mg/kg. • Inhalation LC50 for the mouse is 21800 mg propionaldehyde/m³ air after a 2-hour exposure. • Inhalation LC50 for the rat is between >4671 and <19363 mg propionaldehyde/m³ air after a 4-hour exposure. • Depression of the CNS and respiratory tract irritations are mainly observed after acute exposure. • Undiluted it can be highly irritating to the skin and mucosa depending on the exposure period. Animal studies according to OECD guidelines led to results that characterizes it not to be irritating to skin and eyes. • No indications of a sensitizing effect in humans. Experimental sensitization tests on animals were not conducted. • Subchronic inhalation exposure of rats (6 hours/day, 7 days/week for 7 weeks) resulted in an irritation-related damage of the nasal mucosa. This effect was already observed at an exposure to 365 mg/m³ (151 ppm) for male and female rats. • Systemic effects are not pronounced. (source did not elaborate). • Results of mutagenicity tests vary. • Studies on chronic toxicity or on carcinogenicity are unavailable. • The NOEC (no observed effect concentration) for reproductive-toxic effects via inhalation was 3683 mg/m³ (1522 ppm) or above after a 6-hour exposure per day. [Source did state "or above"]
--	--	---

		<ul style="list-style-type: none"> The NOEC for systemic toxicity was 365 mg/m³ (151 ppm) for male and female rats. <hr/> <p>Source: Driscoll et al. (1992). <u>The OECD screening information data set (SIDS); prioritizing high production volume chemicals for further testing.</u> (full text on request through ILL)</p> <p>SIDS evaluation conducted on propionaldehyde. Inhalation exposure to concentrations of 0, 500, 1000, 1500, and 2500 ppm for 6 hr/day on days 0-20 of gestation. In the 2500 ppm group there was a statistically significant reduction in fetal body weight.</p> <hr/> <p>Source: TOMES</p> <p>RTECS gives various toxicity values (e.g. LD50, LCLo, some of which were given above in NTP).</p> <p>Shepard's Catalog of Teratogenic Agents Slott and Hales (1985) injected 10, 100, or 1000 ug directly into the day 13 rat amnion and found a dose dependent increase in embryoletality but no significant increase in defects.</p> <p>HSDB Acute toxicity of aldehydes in mice, guinea pigs, & rabbits have been studied. All animals exposed to high levels by inhalation developed fatal pulmonary edema. Source did not give doses. (cited original work: Clayton & Clayton (eds.). Patty's Industrial Hygiene and Toxicology) 5-20 mg/kg intraperitoneal in rats increased blood pressure in a dose-related manner. Doses > 20 mg/kg resulted in hypotension and severe bradycardia. (doses/responses not given in source).</p> <p>Rats tolerated inhalation of 90 ppm for 20 days, 6 hr/day with no obvious pathology, although 1300 ppm for 6 days produced hepatic damage.</p> <p>Propionaldehyde affected the CNS of animals, cholinesterase of the peripheral blood, and reduced the number of erythrocytes & hemoglobin of blood. The lowest nonacting exposure level was 0.5 mg/m³.</p> <p>The concentration of 3 umol/plate was not mutagenic in the Ames test; not found to be mutagenic using the Salmonella/microsome preincubation assay.</p> <p>The findings from a study of DNA damage in Chinese hamster ovary cells supports the hypothesis of a carcinogenic effect.</p> <p>LC50: rat, inhalation, 26000 ppm/30 min</p> <p>LOLI[®] available</p>

A 4 - not classifiable as a human carcinogen

Asphyxiation

Source: Standard Report (TSCATS DATA)

Reports listed; selected abstracts follow:

1 & 2. Oncogenicity evaluated in rats exposed to 0, 200, 1000, or 5000 ppm for 7 hrs/day, 5 days/wk for 2 years. Also in mice with the same exposure but only for 18 months. Propene did not show any carcinogenic effects in the rats or mice.

3. Uptake of inhaled propene screened in rats exposed to graded concentrations of either 1, 5, 20, 100, and 500 ppm or 1, 10, 100, 1000 and 5000 ppm by nose-only exposure for 80 minutes at daily intervals. The percent of propene absorbed was calculated to be 8.7% at a vapor concentration between 10 and 100 ppm.

Source: Nordic Expert Group (1995). 117. Propene. (CAS NO 115-07-1)

Classified as an asphyxiant. Human data are scarce.

Inhalation of Propylene on a long-term basis gave rise to no-neoplastic toxic changes in the nasal cavity of rats; in mice, the incidence of chronic focal renal inflammation was increased. In female mice, uterine endometrial stromal polyps increased and, to a lesser extent, hemangiosarcoma as well as hemangioma combined. Authors state that **as the metabolite (propylene oxide) is carcinogenic to experimental animals, it is**

not possible at the present time to rule out propylene as a human carcinogen.

OEL - Switzerland: TWA 10000 ppm(17500 mg/m³)

HSDB

Gross inhalation may cause reduced blood pressure & heart arrhythmia.

Humans: At a concentration of 6.4% for 2.25 min, mild intoxication, paresthesias, & inability to concentrate were noted. However, memory was not impaired. At 12.8% in 1 min. the same symptoms were markedly accentuated & at 24 & 33%, unconsciousness followed in 3 minutes. Human exposure to 23% for 3 to 4 min did not produce unconsciousness. Two subjects exposed to 35 & 40% vomited during or after the experiment, & one complained of severe vertigo. Exposure to 40, 50, & 75% (400,000, 500,000, or 750,000 ppm) for a few minutes caused initial reddening of eyelids, flushing of face, lacrimation, coughing, and sometimes flexing of legs. No variation in respiratory or pulse rates or EKGs were noted. A concentration of 50% prompted anesthesia in 2 min. followed by complete recovery without any physiological indications.

Non-Human Toxicity Excerpts:

Dose of 200, 1000, and 5000 ppm were administered to rats & mice for 7 hr/day, 5 days/wk, for 24 months for the rats and 18 months for the mice. No carcinogenic effects were revealed.

No toxic signs observed when anesthesia was induced in cats with 20 to 31% propylene. Some subtle effects from 40 to 50% (not elaborated on), at 70% blood pressure decrease & rapid pulse. From 50 to 80% an unusual ventricular ectopic beat occurred.

A concentration of 40% produced light anesthesia in rats with no toxic symptoms within 6 hr. & an exposure to 55% for 3 to 6 min, 65% for 2 to 5 min, & 70 % for 1 to 3 min resulted in deep anesthesia with no CNS signs or symptoms.

Found to be a cardiac sensitizer in the dog.

		<p>Chronic exposure of mice to minimal concentration [not specified] caused moderate to very slight fatty degeneration of the liver.</p> <p>Propylene is not mutagenic when tested in E. coli, but conversely, protects against mutation.</p> <p>Chronic toxicity studies. Rats and mice exposed to either 5000 or 10000 ppm for 6 hr/day, 5 days/wk, for 103 weeks. In exposed rats, increased incidences of non-neoplastic lesions were observed in the nasal cavity; epithelial hyperplasia in female rats exposed to the high concentrations and squamous metaplasia in female rats exposed to both concentrations and in male rats exposed to the low concentration. In addition, inflammatory changes characterized by an influx of lymphocytes, macrophages, and granulocytes into the submucosa and granulocytes into the lumen occurred in male rats of both exposure groups.</p> <p>LOLI® available</p>

Table 1 contains sufficient information to calculate an Estimated Permissible Concentration (EPC) for 22 compounds and the Effects Screening Level (ESL) is given for 39 compounds. RfCs were available for cyclohexane, hydrofluoric acid, and 2-propanol; the RfC for propionaldehyde is under review by the USEPA. A total of 22 compounds have insufficient information at this time to derive any type reference value. The basis for calculating EPCs and the source of ESLs are described in Table 2. Table 2 contains calculations of reference values made using the Estimated Permissible Concentration (EPC) method described by Williams et al (1994). EPCs have been calculated using the PEL, TLV, and the lowest reported OEL. A description of the Effects Screening Level (ESL) used by the Texas Natural Resource Conservation Commission (TNRCC) is also provided in Table 2.

Derived from occupational exposure limits, an Estimated Permissible Concentration (EPC) is defined as “the concentration of a chemical, which under continuous exposure conditions, is expected to be devoid of all acute and chronic toxicities.” This methodology stems from an approach originally outlined by Cleland and Kingsbury (1977). It is proposed, based on a comparative analysis of EPCs and USEPA reference values for 103 chemicals, that EPC values represent a reasonably conservative surrogate value when USEPA or state reference values are unavailable and enable a more complete quantification of human health risks. Currently, 39 states use an EPC-like methodology to derive permissible air emission limits in their air toxics programs.

$$\text{Basic Equation: } \text{EPC} = \frac{\text{OEL}}{4.2 \times 100}$$

Effects Screening Levels (ESLs) are currently used by the Texas Natural Resource Conservation Commission (TNRCC) Toxicology and Risk Assessment Staff to evaluate the potential for adverse health effects to occur as a result of exposure to concentrations of constituents in the air. They are based on data concerning health effects, odor nuisance potential, effects with respect to vegetation, or corrosion effects. If measured airborne levels of a constituent do not exceed the screening level, no adverse health or welfare effects would be expected to occur. If the airborne constituents exceed these levels, a more in-depth review is indicated (TNRCC, 1997).

Table 2. Estimated Permissible Concentration (EPC) Values with Available Effects Screening Levels (ESLs) and RfDs & RfCs.

NOTES

(*) All URLs listed above accessed through Scorecard/ Environmental Defense Fund (EDF), (1999). New York. Available online at <http://www.scorecard.org>.

(**) All health effect references for each analyte are listed adjacent to the chemical, with numbers corresponding to the appropriate number in the bibliography.

(***) All health effects (acute, chronic, etc.) are assumed to be human unless otherwise noted.

(****) CAS numbers for each analyte were retrieved from the Grateful Med and Scorecard Internet sites. Available online: <http://www.scorecard.org>.

(*) Indicates the 66 analytes for which there were no reference doses or other information given as part of the original air sampling data from which this list was made.

(#) The Office of Environmental Health Hazard Assessment reviews risk assessments submitted under the Air Toxics AHot Spots@Program (AB2588). Chlorinated dibenzo-p-dioxins and chlorinated dibenzofurans were calculated as total TCDD equivalents in the AB2588 risk assessments. As a result of these equivalent calculations, exposure effects from dibenzofurans will be assumed to be the same as exposure effects from dibenzodioxins. In many of the dioxin and furan compounds listed, no specific health effect information could be located on the individual isomers. Therefore, references 11 and 12 were applied to all the dioxin and furans listed, with additional information provided as other references (particularly 5 and 7) allowed.

Table 1-1
Oral Toxicity Values

Constituent	Oral RfD ^(a)					Oral Slope Factor ^(a)		
	mg/kg-day	Endpoint/Target Organ System	Uncertainty Factor	Source ^(b)	Weight of Evidence	Basis for Carcinogenicity	kg-day/mg	Source ^(b)
<i>Inorganics</i>								
Chloride	--	--	--	--	--	--	--	--
Aluminum	--	--	--	--	--	--	--	--
Arsenic (inorganic)	0.00030	Hyperpigmentation, keratosis and possible vascular complications.	3	IRIS	A	Based on sufficient evidence from human data. An increased lung cancer mortality was observed in multiple human populations exposed primarily through inhalation. Also, increased mortality from multiple internal organ cancers (liver, kidney, ...)	1.5	IRIS
Barium	0.070	Increased blood pressure	3	IRIS	D	Oral exposure studies in rats and mice did not find significant increases in tumor incidence following chronic exposure. Inhalation exposure and intratracheal studies are inadequate for carcinogenicity evaluation.	--	--
Chromium (III)	1.0	No effects observed	100	IRIS	--	--	--	--
Chromium (VI)	0.0050	No effects reported	500	IRIS	A	Results of occupational epidemiologic studies of chromium-exposed workers are consistent across investigators and study populations. Dose-response relationships have been established for chromium exposure and lung cancer. Chromium-exposed workers.	--	--
Fluoride	--	--	--	--	--	--	--	--
Lead (and compounds) (inorganic)	--	--	--	--	B2	Sufficient animal evidence. Ten rat bioassays and one mouse assay have shown statistically significant increases in renal tumors with dietary and subcutaneous exposure to several soluble lead salts. Animal assays provide reproducible results in .	--	--
Manganese (food)	0.14	Central nervous system effects	1	IRIS	D	Existing studies are inadequate to assess the carcinogenicity of manganese.	--	--
Mercury (inorganic)	--	--	--	--	D	No human data are available. Animal and supporting data are inadequate.	--	--
Sulfate	--	--	--	--	--	--	--	--
Thallium ^(c)	0.00008	Increased levels of SGOT and LDH	3000	IRIS	D	Lack of carcinogenicity data in animals and	--	--

Table 1-1
Oral Toxicity Values

Constituent	Oral RfD ^(a)					Oral Slope Factor ^(a)		
	mg/kg-day	Endpoint/Target Organ System	Uncertainty Factor	Source ^(b)	Weight of Evidence	Basis for Carcinogenicity	kg-day/mg	Source ^(b)
Vanadium	0.0070	NOAEL	100	HEAST	--	humans.	--	--
<i>Pesticides/PCBs</i>								
Aroclor 1254	0.000020	Ocular exudate, inflamed and prominent Meibomian glands, distorted growth of finger and toe nails; decreased antibody (IgG and IgM) response to sheep erythrocytes.	300	IRIS	B2	Used slope factor for Polychlorinated biphenyls as a surrogate slope factor for Aroclor 1254.	2.0	IRIS
Chlordane, alpha (as Chlordane)	0.000060	Regional liver hypertrophy in females	1000	IRIS	B2	Sufficient evidence in studies in which benign and malignant liver tumors were induced in four strains of mice of both sexes and in F344 male rats; structurally related to other liver carcinogens.	1.3	IRIS
Chlordane, gamma (as Chlordane)	0.000060	Regional liver hypertrophy in females	1000	IRIS	B2	Sufficient evidence in studies in which benign and malignant liver tumors were induced in four strains of mice of both sexes and in F344 male rats; structurally related to other liver carcinogens.	1.3	IRIS
DDE (p,p'-Dichlorodiphenyldichloroethylene)	--	--	--	--	B2	Increased incidence of liver tumors including carcinomas in two strains of mice and in hamsters and of thyroid tumors in female rats by diet.	0.34	IRIS
DDT (p,p'-Dichlorodiphenyltrichloroethane)	0.00050	Liver lesions	100	IRIS	B2	Observations of tumors (generally of the liver) in seven studies in various mouse strains and three in rats. DDT is structurally similar to other probable carcinogens, such as DDD and DDE.	0.34	IRIS
Heptachlor	0.00050	Liver weight increase in males	300	IRIS	B2	Inadequate human data, but sufficient evidence exists from studies in which benign and malignant liver tumors were induced in three strains of mice of both sexes. Several structurally related compounds are liver carcinogens.	4.5	IRIS
<i>Semi-Volatile Organics</i>								
Acenaphthylene	--	--	--	--	D	No human data and inadequate data from animal bioassays.	--	--
Benzo(a)anthracene	--	--	--	--	B2	No human data from animal bioassays. B(a)A	--	--

-- No Toxicity Information was available on IRIS (4th Quarter), 1998 or HEAST 1997.

^(a)IRIS, 1998 (4th Quarter) (U.S. Environmental Protection Agency. 1998. Integrated Risk Information System. Online Database) or HEAST 1997 (U.S. Environmental Protection Agency. 1997. Health Effects Assessment Summary Tables (HEAST): FY 1997 Update. EPA/540-R-97-036. PB97-921199. July. OSWER, Washington, D.C.).

^(b) PM₁₀ refers to particulate matter less than 10 microns in diameter. Particles larger than 10 microns are not respirable (i.e., they are too large to reach the lung). The current annual air standard for PM₁₀ is 50 ug/m³. The inhalation RfD was derived as follows: 50 ug/m³ * 20 m³/day * 1/70 kg * 1 mg/1000 ug.

^(c)The following polycyclic aromatic hydrocarbons are considered carcinogenic: benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-c,d)pyrene.

13. ABSTRACT (Maximum 200 words) The mission of Naval Air Facility Atsugi is to provide facilities, services and material support for U.S. Navy and Marine Corps aviation operations, and to provide logistic support for Carrier Air Wing FIVE. Approximately 8,000 military personnel and dependents are stationed at NAF Atsugi. A population boom in the early 1970s caused massive expansion in the communities surrounding the base and, as a result, the requirement for disposal of municipal and medical wastes also grew. Currently, the Shinkampo Incinerator immediately adjacent to NAF Atsugi burns over 180 tons of waste per day. Prevailing winds blow emissions from the incinerator stack over highly populated areas of NAF Atsugi. Under contract from the Navy Environmental Health Center, a private environmental consulting firm conducted an ambient air toxics study to evaluate the chemical constituency of the incinerator's emissions. This study examined the ambient air concentration of multiple toxics and criteria pollutants. Over 200 chemicals were identified in the air over NAF Atsugi; however, within the scientific literature, toxicology information suitable for use in human health risk assessment could be found for all but 66 of these chemicals. The present report describes the derivation of appropriate risk assessment reference values from data in the scientific literature and summarizes the health effects of each of the chemicals detected at NAF Atsugi.

GENERAL INSTRUCTIONS FOR COMPLETING SIF 298

The Report Documentation Page (RDP) is used in announcing and cataloging reports. It is important that this information be consistent with the rest of the report, particularly the cover and title page. Instructions for filling in each block of the form follow. It is important to *stay within the lines* to meet *optical scanning requirements*.

Block 1. Agency Use Only (*Leave blank*).

Block 2. Report Date. Full publication date including day, month, and year, if available (e.g. 1 Jan 88). Must cite at least the year.

Block 3. Type of Report and Dates Covered. State whether report is interim, final, etc. If applicable, enter inclusive report dates (e.g. 10 Jun 87 - 30 Jun 88).

Block 4. Title and Subtitle. A title is taken from the part of the report that provides the most meaningful and complete information. When a report is prepared in more than one volume, repeat the primary title, add volume number, and include subtitle for the specific volume. On classified documents enter the title classification in parentheses.

Block 5. Funding Numbers. To include contract and grant numbers; may include program element number(s), project number(s), task number(s), and work unit number(s). Use the following labels:

C - Contract	PR - Project
G - Grant	TA - Task
PE - Program Element	WU - Work Unit Accession No.

Block 6. Author(s). Name(s) of person(s) responsible for writing the report, performing the research, or credited with the content of the report. If editor or compiler, this should follow the name(s).

Block 7. Performing Organization Name(s) and Address(es). Self-explanatory.

Block 8. Performing Organization Report Number. Enter the unique alphanumeric report number(s) assigned by the organization performing the report.

Block 9. Sponsoring/Monitoring Agency Name(s) and Address(es). Self-explanatory.

Block 10. Sponsoring/Monitoring Agency Report Number. (If known)

Block 11. Supplementary Notes. Enter information not included elsewhere such as: Prepared in cooperation with ; Trans. of ; To be published in.... When a report is revised, include a statement whether the new report supersedes or supplements the older report.

Block 12a. Distribution/Availability Statement. Denotes public availability or limitations. Cite any availability to the public. Enter additional limitations or special markings in all capitals (e.g. NOFORN, REL, JTAR).

DOD - See DoDD 5230.24, "Distribution Statements on Technical Documents.

DOE - See authorities.

NASA - See Handbook NH13 2200.2.

NTIS - Leave blank.

Block 12b. Distribution Code.

DOD - Leave blank.

DOE - Enter DOE distribution categories from the Standard Distribution for Unclassified Scientific and Technical Reports.

NASA - Leave blank.

NTIS - Leave blank.

Block 13. Abstract. Include a brief (*Maximum 200 words*) factual summary of the most significant information contained in the report.

Block 14. Subject Terms. Keywords or phrases identifying major subjects in the report.

Block 15. Number of Pages. Enter the total number of pages.

Block 16. Price Code. Enter appropriate price code (*NTIS only*).

Blocks 17. - 19. Security Classifications. Self-explanatory. Enter U.S. Security Classification in accordance with U.S. Security Regulations (i.e., UNCLASSIFIED). If form contains classified information, stamp classification on the top and bottom of the page.

Block 20. Limitation of Abstract. This block must be completed to assign a limitation to the abstract. Enter either UL (unlimited) or SAR (same as report). An entry in this block is necessary if the abstract is to be limited. If blank, the abstract is assumed to be unlimited.
