13. ABSTRACT (Maximum 200 words) Earth Tech was tasked to collect and analyze historical emissions data from Kelly Air Force Base (AFB), TX. They were limited in scope of work to certain years (1970 to 1975 and 1983 to 1989) with the assumption that these were "peak production years" for the support of military actions in Southeast Asia and increased defense activities, respectively. These years would give a "worst case" scenario of the air emissions at Kelly AFB. Earth Tech was also limited in scope of work to specific Air Force industrial processes (jet engine testing, painting, depainting, and degreasing). These industrial processes included the following air pollutants: benzene, toluene, ethylbenzene, xylene, methylene chloride, methyl ethyl ketone, perchloroethylene, components of burned jet fuel (cadmium, chromium, formaldehyde, benzene, arsenic, and 1,3-butadiene), and metals as applicable to painting, depainting, plating, and degreasing operations (to include cadmium and chromium). Based on the data that was analyzed, Earth Tech concluded that the data from the 1980s is the best available data to use for modeling purposes, specifically 1984, 1985, and 1986. Data from the 1970s is often sketchy, and although the confidence levels are the same for the 1970s data as the 1980s data, the 1970s data contains more uncertainty due to the extensive assumptions that were used when reviewing the data. Earth Tech recommends modeling the data using the Tier 1 approach. The Tier 1 analysis is the first part of an EPA three-tiered modeling process, defined in EPA-450/4-92-001, A Tiered Modeling Approach for Assessing the Risks due to Sources of Hazardous Air Pollutants.

Introduction

The Agency for Toxic Substances and Disease Registry (ATSDR) was petitioned by the late congressman Frank Tejeda to perform a public health assessment (PHA) of neighborhoods north and southeast of Kelly AFB because of resident health concerns. ATSDR's PHA report dated September 9, 1999 indicated that there was evidence that residents north and southeast of Kelly AFB "are not currently exposed to levels of contaminants from Kelly AFB that would cause people to become sick." ATSDR concluded in the PHA that, "there is evidence that past air emissions may have been greater (than) current air emissions." However, ATSDR did acknowledge that there was not enough information about past levels of air emissions to determine if there was a public health hazard. ATSDR determined that past air emissions were "indeterminate" due to lack of information.

Background and Scope

Earth Tech was tasked under Contract Number F41624-95-D-9016, Delivery Order 0049 to collect and analyze historical air emissions data from Kelly Air Force Base (AFB), TX in accordance with the Air Force Institute for Environment, Safety, and Occupational Health Risk Assessment (AFIERA) Directorate Statement of Work (SOW) dated 7 February 2000.

Earth Tech was limited in scope of work to certain years (1970 to 1975 and 1983 to 1989) with the assumption that these were "peak production years" for the support of military actions in Southeast Asia and increased defense activities, respectively. These years should give the ATSDR a "worst case" scenario of the air emissions at Kelly AFB. Additionally in the PHA report, the ATSDR commented that the past air emissions were indeterminate and included as possible contaminants volatile organic compounds (VOCs), fuel, and metals from industrial processes and aircraft. Given these conclusions, Earth Tech was limited in scope of work to specific Air Force industrial processes (jet engine testing, painting, depainting, and degreasing). These industrial processes included the following air pollutants: benzene; toluene; ethylbenzene; xylene; methylene chloride; methyl ethyl ketone (MEK); perchloroethylene; components of burned jet fuel (cadmium, chromium, formaldehyde, benzene, arsenic, and 1,3-butadiene); and metals as applicable to painting, depainting, plating, and degreasing operations (to include cadmium and chromium). Finally in order to best model past air emissions, Earth Tech was asked to provide emission stack heights, or if no stack heights were available, building heights, as well as hours of operation, and emission control efficiencies as applicable.

Earth Tech employed Texas Environmental Action and Management, LLC (TEAM) as a subcontractor to recommend how to appropriately utilize the data to model emissions, and describe uses and limitations of the modeling. TEAM was selected because of their relevant related experience, including air emissions estimating and air emissions modeling. Additionally, TEAM reviewed all of the data gathered from the bioenvironmental engineering casefiles including AF Forms 2761 (Hazardous Materials Inventory) and industrial hygiene area sampling information to best estimate air emissions from certain processes. TEAM's report can be found in Appendix B of this report. TEAM's air emissions estimates can be found in Appendix D. Because of the varying data sources, TEAM's estimates may differ from Earth Tech's with regard to presentation and calculations.

Because of the potential for spurious and inferred data, Earth Tech was asked to provide assumptions regarding the certainty of the data as to high, medium, or low confidence levels. Explanations regarding the method used to estimate the certainty of the data is discussed below.

Data Collection

Data collection activities were conducted from October 12, 1999 through January 28, 2000 and consisted of information gathering, consolidation, and interviews with current and former employees.

Information Gathering

Prior to 1989, Kelly AFB Bioenvironmental Engineering Services (BES) led the assessment of the base's air emissions inventories. Earth Tech examined over 500 BES casefiles (workplace hazard assessments) at the Kelly AFB BES office for information regarding stack testing, air emissions inventories, air sampling, and Texas Air Control Board (TACB) air permitting data. Information regarding chemical use (found on AF Forms 2761) was also gathered, as well as any production information, hours of operation, and operational information. Additionally, Earth Tech gathered some information at the Air Quality Branch of the Air Force Institute for Environment, Safety, and Occupational Health Risk Analysis (AFIERA) at Brooks AFB.

Telephone Contacts

Kelly AFB Environmental Management (Kelly EM) provided Earth Tech with points of contact (POCs) at the following Workcenters:

1. Jet Engine Testing at building 655 (LP)
2. Building 360
3. Paint operations at building 329 (LDPAA)
4. Aircraft maintenance and repair (TIP)
5. Power Systems Program Management (LD)
6. Transient alert (OS)
7. Chrome plating, building 301
8. Bioenvironmental Engineering
9. Civil Engineering (CE)
10. 433rd Air National Guard
11. Kelly AFB History Office

Outside Source Contacts

Earth Tech also contacted other entities that may have had information regarding production or processes:

1. HQ AFMC, Wright Patterson AFB, OH
2. AFIERA/Air Quality, Brooks AFB, TX
3. Warner Robins AFB, GA (Paint Shop)
4. Randolph AFB, TX (Aircraft Paint Shop)
5. Wright Patterson AFB Research Laboratory

Finally, the California Air Regulatory Board (CARB), the Aircraft Environmental Support Office (AESO) Naval Aviation Depot, San Diego, CA, and Southwest Research Institute in San Antonio, TX were contacted with regard to jet engine emissions, specifically, the speciation of JP-4 jet engine emissions.

Information that could not be gathered regarding emissions testing and process information (such as Material Safety Data Sheet or MSDS information) was gathered on the Internet. Sources on the Internet are listed in the reference section.

Other means of data collection included interviews with personnel who worked at Kelly AFB (in the Workcenters listed above in *Telephone Contacts*) in the following disciplines: jet engine testing, chrome plating, vapor degreasing, painting, and depainting. Interviews were conducted informally and consisted of questioning the former and present workers, as well as pursuing further leads. Previous workers in buildings 258 and 259 (which were demolished in 1979-1980) provided process information regarding chromium plating and estimated stack and building height.

Earth Tech organized the data into Microsoft Excel® spreadsheets by year emitted, and provided a summary sheet that broke out emissions by decade, building, and total emissions for the 1980s. Only the 1980s data was totalled because it was the most complete data set. The spreadsheets include the building and process, chemical, and calculations in tons per year and pounds per hour of operation. Stack heights are also included where possible. Occasionally, the data reported were for a particular process rather than a building, so stack heights could not be determined.

Confidence Levels

Confidence levels were established on the best available data including assumptions made from existing data and whether the data are consistent. For instance, emission points (identifiers for exhaust or stack locations) from 1984 data did not match earlier emission points in 1975, so these could not be assigned a high confidence level. Additionally, if all criteria for a confidence level could not be met, the next lowest confidence level was assigned. The confidence level matrix is defined below:

High

- Emission points (locations of stacks) are exact
- Loss rates through evaporation and reclamation are known, not assumed
- Exact emission factors known or available
- Data gathered from actual inventory
- Stack heights are known and correspond to the emitter

Medium

- Emission points are not available, but with further study, could be determined (eg: column number is known, but could confirm through examination of construction drawings)

- Emission factors are estimated based upon current practices (eg: using JP-8 data to estimate jet engine emissions prior to 1991 that used JP-4*, and using/not using controls for chromium plating mist reduction)
- Loss rates are unknown
- Data was gathered from inventory using additional input from known processes and/or personnel interviews
- Stack heights assumed from best available data

Low

- Emission points unknown (building demolished or data is grouped by chemical)
- Emission factors are unknown or unavailable
- Loss rates are unknown or unavailable
- Data gathered solely from interviews
- Stack heights unavailable (building demolished)

Confidence levels for each emission estimate can be found on the respective spreadsheet. All of the air emissions estimates were assigned a "Medium" confidence level because of missing data, with the exception of data for buildings 258 and 259 and data for 1967. Since buildings 258 and 259 were demolished, most of the operational, emission point, and stack or building height data was from interviews or otherwise assumed. Because of these many assumptions, all data for buildings 258 and 259 are of a low confidence level. Because the data from 1967 does not include speciation information for jet engine testing it is also assigned a low confidence level.

Assumptions and Other Observations

Many of the data points were provided by the documentation reviewed; therefore, if there is no entry or "N/A" in a spreadsheet cell, it can be assumed that the data presented were already calculated. Data that were provided in tons per year were further broken down by emissions in pounds per hour. In many cases, the hours of operation were provided, but where they were not, a 5 day per week, 24 hour per day operation was assumed.

Emission points were provided only where they were documented. Earth Tech tried to assign emission points; however, when emission points for 1984 and 1975 were compared, there was very little correlation, leading Earth Tech to believe that the emission points had been changed throughout the years.

All calculations were in accordance with the AFIERA AEI Guidance document*.

Where possible, Earth Tech cross-checked data with hand-written notes, or submissions from questionnaires that were submitted to the TACB.

There was not a substantive amount of information regarding painting operations, other than total volatile organic compound (VOC) totals. Earth Tech tried to get information regarding aircraft

* JP-8 emission factors were applied to JP-4 combustion processes because JP-4 emission factors do not exist for the chemicals within scope. Personnel familiar with this process revealed that the jet engine testing process has not changed much since the 1970s.

painting operation; however, there were no records found that provided the type of paint used except for year 1986. Interviews to get this type of information proved ineffective due to the length of time that has spanned since personnel worked in this area (e.g., personnel cannot remember specific process information that far back).

Earth Tech was unsuccessful in gathering documentation regarding abrasive blasting operations because of the lack of data.

Chrome plating emissions were estimated only where original estimates were documented. Although Earth Tech had access to amounts of chromic acid used in the process, information regarding the tank surface area, amount of hard electroplating versus decorative, and the power at which the electroplating was performed was difficult to obtain because of the sole reliance upon personal memory from interviews. All of these components are used in the recommended emissions calculations; therefore, estimates from the amount of material used were not performed.

For the T-56 engine, there was some emission factors at the idle setting that were missing, so the approach setting was used.

For all solvent use (methylene chloride, methyl ethyl ketone, and toluene), it was assumed that 100% volatilization occurred because the solvents were wiped on or sprayed. For degreasing operations, 25% volatilization was assumed because perchloroethylene is used in tanks; therefore more of an enclosed process.

Where phenolic stripper was used, Earth Tech assumed that the methylene chloride in the stripper had a 60% concentration based on an MSDS.

Problems Encountered

Supporting documents were sometimes hard to find. Earth Tech could not find any information regarding speciation of emissions from jet engines using JP-4 fuel. The only information found was for criteria pollutants: particulates, oxides of nitrogen, oxides of sulfur, carbon monoxide, carbon dioxide, and total hydrocarbons.

The building heights and stack heights are listed in Appendix A, and were gathered by Earth Tech through review of air emissions inventories, Kelly AFB Civil Engineering construction drawings, and by the use of an electronic distance meter. Building and stack heights were often unavailable in Civil Engineering. Some buildings had been demolished and Kelly AFB Civil Engineering often did not have the construction drawings. Additionally it was often not possible to determine if the stack corresponded with the hazard. For example, a stack height would be useless when dealing with aircraft paint stripping with methylene chloride because the methylene chloride is not vented, but rather volatilized into the ambient air. Many stacks were nothing more than exhaust vents (i.e., over vapor degreasing tanks), and it was not possible to determine if the stack had been modified.

Interviews were conducted with POCs provided by Kelly EM. Interviews were attempted for aircraft painting; however, little information was gathered due to lack of documentation. Because these operations took place 15 to 25 years ago and the processes have changed, many people could not remember details regarding quantities of chemical used or what types of emission controls were in place. Telephone calls placed to the primary POCs listed under the "Data Collection" section were returned on a regular basis; however, phone calls made as a result of pursuing a further lead often ended with no fruitful information.

No data for one single year appeared comprehensive with regard to complete, speciated air emissions. Assumptions were made and are outlined in the previous section. Earth Tech's air emissions estimates can be found in Appendix C.

Conclusions and Recommendations

Based on the data that has been gathered and analyzed, Earth Tech concludes that the data from the 1980s is the best available data to use for modeling purposes, specifically 1984, 1985, and 1986. Data from the 1970s is often sketchy, and although the confidence levels are the same for the 1970s data as the 1980s data, the 1970s data contains more uncertainty due to the extensive assumptions that were used when reviewing the data.

In concordance with TEAM, Earth Tech agrees that this data is best modeled using the Tier 1 approach. The Tier 1 analysis is the first part of an EPA three-tiered modeling process, defined in EPA-450/4-92-001, *A Tiered Modeling Approach for Assessing the Risks due to Sources of Hazardous Air Pollutants*. Tier 1 analyses are performed when there is a question of whether or not the identified source has the potential to cause a significant impact.

Earth Tech recommends that only building heights be used for modeling because of the disparity in stack heights and the uncertainty of the locations and functions of the stacks. Additionally, Earth Tech recommends that Kelly AFB consider industrial facilities that surround the base as a potential source of emissions.

**APPENDIX B
TEAM, LLC REPORT**

THIS PAGE LEFT INTENTIONALLY BLANK

HISTORICAL AIR EMISSIONS ESTIMATES
KELLY AFB, TEXAS
Contract Number F41624-95-D-0016
Delivery Order 49

Purpose: The purpose of this document is to present the results of Texas Environmental Action and Management, LLC's (TEAM) consolidation and analysis of historical air emissions data collected at Kelly Air Force Base (AFB), Texas. Specifically, TEAM was tasked to (1) review gathered data and assess any calculations and assumptions that can be made from the data as being of a high, medium, or low level of confidence, (2) provide consulting recommendations regarding the feasibility of conducting air modeling with the subject data, and (3) prepare a written summary report. The scope of the data review was limited to the following processes: jet engine testing, aircraft painting, aircraft depainting, degreasing, and chrome plating. The chemicals were limited to the following: toluene, methyl ethyl ketone, methylene chloride, perchloroethylene, xylene, and components of burned jet fuel as applicable to jet engine testing emissions (to include cadmium, chromium, formaldehyde, benzene, arsenic, and 1,3-butadiene, and metals as applicable to the painting, depainting, plating, and degreasing operations. Mr. Charles Attebery, PE and Ms. Nancy Miller, PE, who are both former Air Force (AF) bioenvironmental engineers, conducted all work in accordance with the guidance documents described in Paragraph 1.4 of the Statement of Work. TEAM utilized additional guidance documents including *A Tiered Modeling Approach for Assessing the Risks Due to Sources of Hazardous Air Pollutants* (EPA, 1992).

Background: This study of historical emissions data was made in response to an Agency for Toxic Substances Disease Registry (ATSDR) Public Health Assessment (PHA) conducted at Kelly AFB that stated, "available data on past usage or emissions for many contaminants was insufficient or not suitable for analysis. There is evidence that past air emissions may have been greater than current air emissions."

ATSDR based many of its conclusions and recommendations on air modeling conducted with 1996 data. It noted in its report that emissions air modeling uncertainty cannot be accurately quantitated, and that several sources of error exist. ATSDR also noted the rate of emission, physical location of emission, or the physical form of the chemical in emission as sources of uncertainty. It also noted that meteorological data, decay rates, deposition rates, or obstructions impact modeling results. It identified data gathering and calculations as sources of error. ATSDR specifically noted that the estimation of past emissions might contain error because it is not known how representative the selected values were.

ATSDR stated in its report that the level of exposure to contaminants from Kelly AFB remains uncertain and will remain so, due to the unavailability of past emissions data. It recommended that a method of determining potential past emissions of contaminants from Kelly AFB be identified. Based on this recommendation and public concern that Kelly AFB contributed to area health impacts, Kelly AFB issued a delivery order

(F41624-95-D-0016-0049) to EARTH TECH, Inc. (EARTH TECH) to assess historical air emissions records at Kelly AFB. The purpose of the assessment was to determine if any method of calculating or estimating potential past contaminant emissions from Kelly AFB results in data suitable for use in emissions air modeling.

Relevant background information on the Agency for Toxic Substances Disease Registry (ATSDR) mission and other useful information can be found on the Internet at URL <http://atsdr1.cdc.gov:8080/HAC/pha.html>.

The United States Environmental Protection Agency (EPA) agrees that air emissions models have limitations and has taken steps, through the preparation of guidance documents, to simplify air emissions dispersion analyses in the determination of health effects. EPA guidance defines a three-tier process in EPA-450/4-92-001, *A Tiered Modeling Approach for Assessing the Risks due to Sources of Hazardous Air Pollutants*. The approach is especially useful and cost effective in screening historical data, which may be incomplete, collected for other purposes, or suspect with regard to data quality. The three-tier approach is as follows:

Tier 1 Analyses: Tier 1 analysis of a stationary source (or group of sources) of toxic pollutant(s) is performed to address the question of whether or not the source has the potential to cause a significant impact. This "screening" analysis is performed by using tables of lookup values to obtain the "worst-case" impact of the source being modeled. The analysis is performed to assess both the potential long- and short-term impacts of the source. If the predicted screening impacts are less than the appropriate levels of concern, no further modeling is indicated. If the predicted screening impacts are above any levels of concern, further analysis of those impacts at a higher Tier may be desirable to obtain more accurate results.

The Tier 1 "lookup tables" have been created as tools that may be easily used to estimate conservative impacts of sources of toxic pollutants with a minimal amount of information concerning those sources. The normalized annual and 1-hour concentration tables were created based on conservative simulations of toxic pollutant sources with Gaussian plume dispersion models. In this context, "conservative" simulations use conservative assumptions regarding meteorology, building downwash, plume rise, etc.

Tier 2 Analyses: Tier 2 analysis of a stationary source (or group of sources) of toxic pollutant(s) may be desired if the results of a Tier 1 analysis indicate an exceedance of a level of concern with respect to one or more of the following: (1) the maximum predicted cancer risk; (2) the maximum predicted chronic noncancer hazard index, or; (3) the maximum predicted acute hazard index. Note that in situations where only one or two of the Tier 1 criteria are exceeded, only those analyses, which exceed the Tier 1 criteria, may need to be performed at the higher Tier. For example, if the Tier 1 analysis showed cancer risk and chronic noncancer risks to be of concern while the acute risk analysis showed no cause for concern, only long-term modeling for cancer risk and chronic noncancer risk may need to be performed at Tier 2. Tier 2 analyses are slightly more sophisticated than Tier 1 analyses, and therefore require additional input information as well as a computer for their

execution. Tier 2 analyses are structured around the EPA's SCREEN model and its corresponding documentation. The SCREEN model source code and documentation is available through the OAQPS TTN (see Appendix A in EPA-450/4-92-001).

Again, similar to the Tier 1 analysis, if any of the predicted impacts from Tier 2 are above the appropriate levels of concern, further modeling is indicated at a higher Tier.

Tier 3 Analyses: Tier 3 analysis of a stationary source (or group of sources) of toxic pollutant(s) may be desired if the results of a Tier 2 analysis indicate an exceedance of a level of concern with respect to one or more of the following: (1) the maximum predicted cancer risk; (2) the maximum predicted chronic noncancer hazard index, or; (3) the maximum predicted acute hazard index. Tier 3 analysis of a stationary source (or group of sources) of toxic pollutant(s) is performed to provide the most scientifically-refined indication of the impact of that source. This Tier involves the utilization of site-specific source and plant layouts as well as meteorological information. In contrast to the previous Tiers, Tier 3 allows for a more realistic simulation of intermittent sources and combined source impacts. In addition, results from short-term analyses indicate not only if a risk level of concern can be exceeded, but also how often that level of concern might be exceeded during an average year. Dispersion modeling for the Tier 3 analysis procedure is based on use of the EPA's Industrial Source Complex (ISC2) model, and as such utilizes many of the same techniques recommended in the "Guideline on Air Quality Models (Revised)" approach to the dispersion modeling of criteria pollutants.

To facilitate the dispersion modeling of toxic air pollutants, the EPA has developed TOXLT (TOXic modeling system Long-Term) for refined long-term analyses, and TOXST (TOXic modeling system Short-Term) for refined short-term analyses. The TOXLT system incorporates the ISCLT2 (long-term) directly to calculate annual concentrations and the TOXST system incorporates the ISCST2 (short-term) model directly to calculate hourly concentrations. Codes and user's guides for both TOXLT and TOXST are available via electronic bulletin board (see Appendix A in EPA-450/4-92-001).

Data Summary: TEAM summarized various emissions and chemical usage data gathered by EARTH TECH for the subject chemicals. The data were organized by building/process, chemical, and year/decade emitted/used, where possible. Emissions and usage records spanned almost 30 years. The majority of the data was from the 1980s, followed by 1970s data. EARTH TECH collected little 1990s data. Approximately one-half of the data consisted of "baseline" chemical usage data that was collected or verified on an annual basis by the Base Bioenvironmental Engineering Services (BES) office for the primary purpose of evaluating occupational exposures to the workers who used the chemicals. The balance of the data consisted of various sampling events ranging from area samples of specific operations to personal sampling of personnel to stack emissions sampling. No one source of data for a single shop or building spanned each decade. Data summary tables that identify the level of confidence that should be placed on data for modeling purposes are included as Attachment A.

Assessment of EARTH TECH Assumptions and Calculations: TEAM did not identify an improved alternative to the data gathering approach employed by EARTH TECH. EARTH TECH personnel collected 'best available historical usage and emissions data' from the Kelly AFB BES's industrial hygiene casefiles in its attempt to speciate bulk Kelly AFB air emissions into the subject chemicals. EARTH TECH employed a reasonable approach to calculating emissions from jet engine testing, using scarce data on *speciated* emission factors for various jet engines, estimates of test time periods, and an estimate of the number of tests conducted. The EARTH TECH approach offers the best chance of identifying and/or calculating speciated emissions for the subject chemicals and processes.

Consulting Observations, Conclusions and Recommendations:

Observations and Conclusions

- There is significantly more 'best available data' from the 1980s than from the 1970s.
- The use of trichloroethane in the 1970s appears to have been phased out in favor of methylene chloride and perchloroethylene in the 1980s.
- The 1970s data focused on trichloroethane studies and sampling.
- Summary calculations (by chemical) for the 1970s data do not appear to be a comprehensive listing of emissions (overall accuracy is low).
- Summary calculations (by chemical) for the 1980s data appear to be a comprehensive listing of emissions as verified by comparison to some Kelly AFB annual emissions estimates (overall accuracy is moderate).
- The 1980s 'best available data' appears adequate to perform EPA Tier 1 air emissions modeling, although additional data including stack height and distance of each stack to the nearest receptor needs to be collected.
- The 1970s 'best available data' appears incomplete and is not adequate to perform EPA Tier 1 air emissions modeling.
- None of the 'best available data' included in this assessment is adequate to perform EPA Tier 2 or Tier 3 air emissions modeling.
- The air emissions modeling (Tier 1) that can be conducted with the 1980s data will yield a gross approximation of exposure outside Kelly AFB boundaries.

Recommendations

- Collect or estimate stack height(s) and distance(s) from sources to the Kelly AFB boundary and other information required to perform EPA Tier 1 air emissions modeling.
- Perform EPA Tier 1 modeling for 1980s data.

ATTACHMENT A

Data Assessment Methodology: Kelly AFB BES was the source of the 'best available data' collected by EARTH TECH and reviewed by TEAM. BES is primarily responsible for identifying and evaluating occupational exposures to hazardous materials and providing necessary recommendations to ensure worker protection. BES also performs environmental monitoring, as well numerous other duties. In the past BES, produced annual Air Emissions Inventory (AEI) reports. These duties require BES personnel to maintain records of chemical usage throughout the base. In the 1970s and 1980s this data was predominately collected by visiting the workplace and performing a physical inventory of the chemicals used by the workplace. BES recorded this chemical usage information for each workplace on an AF Form 2761, *Hazardous Material Inventory*. BES then evaluated the chemical usage information and determined personal and area contaminant concentration sampling needs. Personal and area contaminant concentration sampling results are recorded on AF Form 2750, *Industrial Hygiene Sampling Data*. All chemical usage and sampling information is maintained in a casefile for each industrial workplace. Today, the majority of this information is collected using a variety of computerized material tracking systems and verified during workplace visits.

Data included chemical usage and personal/area air sampling results that spanned from the early 1970s through the early 1990s. No data for a single year appeared comprehensive with regard to a complete set of chemical usage, sampling, or AEI results. TEAM calculated annual emissions of the subject chemicals using the following assumptions:

- General chemical exposure and usage did not significantly change during either the 1980s and 1970s as 10-year groups.
- TEAM prioritized calculated and actual air emissions data contained in AEIs or casefiles as the highest quality and gave it priority if two sources of data were available for the same building during either the 1980s or 1970s.
- TEAM prioritized baseline chemical usage data as the second most reliable source of data that could be converted to an estimate of emissions by assuming a percent volatilization during use.
- TEAM prioritized personal sampling data as the least reliable source of data that could be converted to an estimate of emissions by assuming a volumetric flowrate and annual operations time period.
- TEAM assumed a standard volumetric air flow rate of 10 cubic feet per minute to convert personal air sampling results to estimate emissions for specific chemicals from personal or area sampling results.
- TEAM assumed a standard annual operations time period of one day (8 hours) per week for 52 weeks to estimate emissions for specific chemicals from personal or area sampling results.
- TEAM utilized worst case values (values resulting in the highest emission rate) when more than one set of chemical usage data of equal quality were available.
- TEAM utilized an arithmetic average where more than one personal or area sampling data were available for a specific building or operation.

-
- TEAM assumed that degreasing operations lead to a 25% volatilization of the degreasing chemical. It was assumed that perchloroethene (PCE) was used as degreasers in tanks or some other type of system where, ultimately, 75% of the material was disposed via some method other than evaporation.
 - TEAM assumed that painting/coating operations lead to a 100% volatilization of paint/coating solvent and thinner components.
 - TEAM assumed that 2.5% of coatings such as zinc chromate primer is lost through overspray during painting operations.
 - TEAM assumed that the use of cleaning solvents lead to a 100% volatilization of the solvent. It was assumed that ethyl benzene, methylene chloride, toluene, and methyl ethyl ketone (MEK) was used in a manner where 100% of the material volatilized, such as aerosol or wipe on/wipe off applications.

	TF-33 Engine at idle					Olefins Aromatics Total Aldehydes				4.36E+01 1.19E+01 7.80E+00			as carbon atoms as carbon atoms as formaldehyde

Notes:

1. This data is from actual testing data but it did not speculate aromatics, and aldehydes. Since testing hours were not provided, further emission calculations could not be performed.
2. It is assumed the aromatics includes benzene, toluene, xylenes, and ethylbenzene
3. It is assumed that total aldehydes includes formaldehyde.
4. Emissions are in lbs per hour; however, it is not known if this is per year, or per operational hours.

Notes:

1. Data was taken directly from the Texas Air Control Board questionnaire and cross-checked with the APSIS computer print out, which accounts for the rounding.
2. 100% volatilization was assumed for all organic solvent use, 25% volatilization was used for degreasing.
3. Hours of operation, if not listed in the original documentation are assumed to be 24 hours per day, 5 days per week.
4. Equations taken from IERA AEI Guidance document, reference number 1.

1976, 1988, and 1989 Data

Notes:

- 100% volatilization was assumed for all organic solvent use, 25% volatilization was assumed for degreasing.
- Hours of operation, if not listed in the original documentation are assumed to be 24 hours per day, 5 days per week.
- Chromic acid emissions are estimated based on documentation from a plating shop survey, and include accommodations for a 25% loss of the chromic acid. Data was reported in grams per day and converted to tons per year and pounds per hour (based on 24 hours per day operation). All chromium is assumed hexavalent.
- A concentration of 60% methylene chloride was assumed for all phenolic stripper, based on information from the MSDS.
- Equations taken from IERA AEI Guidance document, reference number 1

Notes:

1. 100% volatilization was assumed for all organic solvent use, 25% volatilization was assumed for degreasing.
2. Hours of operation, if not listed in the original documentation are assumed to be 24 hours per day, 5 days per week.
3. For the TF-39 engine, fuel flow is 1,448 lbs of fuel/hour and for the T-56, the flow is 724 lbs of fuel/hour (Reference number 1). Emission factors (in lbs pollutant/1000 lbs fuel) for each chemical can be found in the IERA AEI Guidance document (Reference number 1). Also, a 60 minute test time at idle was assumed for incomplete combustion. No emission factors are available for the T-56 engine for ethylbenzene, toluene, and o-xylene at the idle setting, so factors for the approach setting were used.
4. Emission factors and fuel flow factors are for JP-8 and not JP-4. Speciation information does not exist for JP-4.
5. Equations taken from AEI Guidance document, reference number 1

Confidence Level: Medium based on assumed hours of operation, lack of building numbers, and emission point data.

Notes:

1. Building 340 tested a number of small gas-turbine engines (GTE). All of the model engines were listed, but the only model that Earth Tech could find an emission factor for was the GTEP85-180. All engines were assumed to be GTEP85-180 for the purpose of this estimate.
2. 100% volatilization was assumed for all organic solvent use. 25% volatilization was assumed for degreasing.
3. Hours of operation, if not listed in the original documentation are assumed to be 24 hours per day, 5 days per week.
4. Emission factors and fuel flow factors are for JP-8 and not JP-4. Documentation for JP-4 does not exist.
5. For the GTEP 85-180 engine, fuel flow is 270 lbs of fuel/hour (Reference number 1). Emission factors (in lbs pollutant/1000 lbs fuel) for each chemical can be found in the IERA AEI Guidance document (Reference number 1). Also, a 60 minute test time at idle was assumed for incomplete combustion. No emission factors were available for Methyl Ethyl Ketone.
6. A concentration of 60% methylene chloride was assumed for all phenolic stripper.
7. It is assumed that all hard and decaolative electroplating was accounted for, as well as anodizing. It is also assumed that the estimates take into controls (if any) used.
8. Equations taken from AEI Guidance document, reference number 1.

Notes:

1. Building 340 tested a number of small gas-turbine engines (GTE). All of the model engines were listed, but the only model that Earth Tech could find an emission factor for was the GTEP85-180. All engines were assumed to be GTEP85-180 for the purpose of this estimate.
2. 100% volatilization was assumed for all organic solvent use, 25% was assumed for degreasing
3. Hours of operation, if not listed in the original documentation are assumed to be 24 hours per day, 5 days per week.
4. Emission factors and fuel flow factors are for JP-8 and not JP-4. Speciated emission factors for JP-4 do not exist.
5. For the GTEP 85-180 engine, fuel flow is 270 lbs of fuel/hour, for the TF-39 engine, the fuel flow is 1,448 lbs of fuel/hour, and for the T-56 engine, the fuel flow rate is 724 lbs of fuel/hour (Reference number 1). Emission factors (in lbs pollutant/1000 lbs fuel) for each chemical can be found in the IERA AEI Guidance document (Reference number 1). Also, a 60 minute test time at idle was assumed for incomplete combustion. No emission factors were available for Methyl Ethyl Ketone for the GTEP 85-180 engine. No emission factors for the idle setting were available for ethylbenzene and o-xylene for the T-56 engine, so approach emission factors were used.
6. A concentration of 60% methylene chloride was assumed for all phenolic stripper.
7. Methyl Ethyl Ketone (MEK) is in both parts of a 2-part paint. The percentage of MEK is a result of a volume per volume average.
8. Zinc Chromate and MEK were used only for 8 months of the year, however it is assumed that the same proportion was used for the other 4 months for the most conservative estimate.

Notes:

- 100% volatilization was assumed for all organic solvent use, 25% volatilization was assumed for degreasing.
- Hours of operation, if not listed in the original documentation are assumed to be 24 hours per day, 5 days per week.
- A concentration of 60% methylene chloride was assumed for all phenolic stripper.
- There was less than 5% stironilum chromate in the paints, which Earth Tech did not consider a calculable amount.
- Although the primer consisted of 2 parts, it was not necessary to combine the two since there was 10% MEK in part one and 15% toluene in part two.
- Methyl Ethyl Ketone (MEK) is in both parts of a 2-part paint. The percentage of MEK is a result of a volume per volume average.
- Equations are taken from AEI Guidance document, reference number 1.

General Equation for General Air Emissions

1. Density of chemical in lbs/gal = specific gravity of chemical x density of water (8.33)
2. Emissions in tons per year = (density of chemical in lbs/gal x concentration of chemical x assumed volatilization) / 2000 lbs per ton
3. Emissions in pounds per hour = emissions in tons per year x 2000 / operating hours
4. Emissions in pounds per hour for painting activities = emissions in tons per year x 2000 / (time to paint one aircraft x 24 hours x number aircraft painted per year)

Note: If concentration of chemical or volatilization was 100%, no input was required.

Inputs for General Air Emissions

	Specific Gravity
Perchloroethylene	13.5
Methylene Chloride	11.1
Toluene	7.2
Methyl Ethyl Ketone	6.75

Equation for Jet Engine Testing

General equation: Emissions = emission factor (in pounds of pollutant per 1000 pounds of fuel) x fuel flow factor (in pounds of fuel per hour) / 2000 lbs per ton

Note: Fuel flow factors and emission factors can be found in respective worksheets.

Styrene	100425	5.16E-05	1.91E-04
Total HAPs		1.22E-02	4.51E-02

This table summarizes the hazardous air pollutants which are typical fuel combustion by-products. An expanded pollutant target list, and data qualifiers is provided in Volume II.

Note: A blank represents a compound that was not detected.

* - Emission factors provided in pounds per thousand pounds of fuel were calculated using the lbs/hr rate and the fuel flow rate.

Results reported as 0.00 indicate a detected ambient pollutant concentration greater than the detected pollutant concentration in the exhaust stream.

APPENDIX D
.TEAM, LLC'S AIR EMISSIONS ESTIMATE

THIS PAGE INTENTIONALLY LEFT BLANK

Worksheet Legend

The following paragraphs explain the purpose of each worksheet included in this workbook.

Summary Emissions Estimates - The data included in this worksheet should be used by ATSDR for modeling purposes. The worksheet includes the compiled emissions in tons per year for the target chemicals. The data was prioritized using the assumptions listed in Appendix B. All data conversions are performed in this worksheet.

Raw Data (Complete Data Set) - This worksheet includes all data included in the information sources provided. No calculations or data reduction is performed in this worksheet.

1990s (Sorted) - This worksheet includes the data for the 1990s included in the information sources provided. This data was extracted from the Raw Data (Complete Data Set) worksheet. All data used in the Summary Emissions Estimates worksheet is highlighted in blue.

1980s (Sorted) - This worksheet includes the data for the 1980s included in the information sources provided. This data was extracted from the Raw Data (Complete Data Set) worksheet. All data used in the Summary Emissions Estimates worksheet is highlighted in blue.

1970s (Sorted) - This worksheet includes the data for the 1970s included in the information sources provided. This data was extracted from the Raw Data (Complete Data Set) worksheet. All data used in the Summary Emissions Estimates worksheet is highlighted in blue.

Engine Running Time - This worksheet includes the calculations used to estimate aircraft engine emissions during testing.

Calculations - This worksheet includes the conversion factors used to convert the various data types included in the original data set.

Estimated Emissions per year

			1980s data					1970s data					
Building	Description	Chemical	Usage	Units	Concentration (mg/m3)	Estimated Emissions (Tons/yr)	Notes	Usage	Units	Concentration (mg/m3)	Estimated Emissions (Tons/yr)	Notes	
258	Unknown	Chromic Acid									0.0165	1.28E-07	Assume 100 CFM volume emission; 1978 data
259	Unknown	Chromic Acid									0.0415	3.23E-07	Assume 100 CFM volume emission; 1975 data
301	Chromic Acid Stack Concentration	Perchloroethylene											Assume 100 CFM volume emission; 1975 data
301	Chemical Cleaning	Stack Sample									30	2.33E-04	Assume 100 CFM volume emission; 1978 data
301	Chemical Cleaning	Perchloroethylene			2.15	1.67E-05	Assume 100 CFM Volume; 1980 data						
		Ethyl Benzene	405 T/yr			1.01E+02	Assume 25% volatilization						
		Methylene Chloride	0.016 gal/mo			6.66E-04	Assume 100% volatilization						
		Toluene	1.485 gal/mo			9.87E-02	Assume 100% volatilization						
		Methyl Ethyl Ketone	6.668 gal/mo			2.77E-01	Assume 100% volatilization						
305	MATPME Paint Shop	Chromic Acid	3.6 gal/mo			1.46E-01	Assume 100% volatilization						
308	Electronics	Toluene	20 gal/mo			6.75E-02	Assume 2.5% overspray						
		Methylene Chloride	25 gal/mo			1.04E+00	Assume 100% volatilization						
		Methyl Ethyl Ketone	1 gal/mo			6.65E-02	Assume 100% volatilization						
		Toluene	2 gal/mo			8.10E-02	Assume 100% volatilization						
324	Metallizing/coatings	Methyl Ethyl Ketone	6 gal/mo			2.43E-01	Assume 100% volatilization; Assume worst case value (1985.6 gal/mo)						
329	Paint Area Facility	Toluene	0.75 gal/mo			3.12E-02	Assume 100% volatilization						
347	Jet test stands	Perchloroethylene	4.34 T/yr			1.09E+00	Assume 25% volatilization; Assume that all emissions are perchloroethylene						
348		Benzene	107697 mins testing				1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						
		Ethylbenzene	107697 mins testing			1.86E-01	1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						
		Formaldehyde	107697 mins testing			2.42E-02	1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						
		Methyl Ethyl Ketone	107697 mins testing			1.50E+00	1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						
		Toluene	107697 mins testing			5.07E-02	1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						
		m,p Xylene	107697 mins testing			1.06E-01	1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						
		o Xylene	107697 mins testing			1.21E-02	1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						
			107697 mins testing			1.25E-02	1982 tests conducted in 1982; average 78 mins per test; total is 107,697 mins testing per year; T-56-A7 emission factors						

Building	Description	Chemical	1990s data				1970s data						
			Usage	Units	Concentration (mg/m3)	Estimated Emissions (Tons/yr)	Usage	Units	Concentration (mg/m3)	Estimated Emissions (Tons/yr)	Notes		
348	Degreaser(s)	Perchloroethylene					6.35E+01				3.90E-01	Assume Perchloroethylene is degreaser (100%); calculated value from AEI	Assume 25% volatilization; 1978 data
360	Paint Shop	Perchloroethylene					4.74E+01					Calculated value from 1987/1989 AEI; assume all degreasers contain Perc	Assume 100 CFM volume emission; 1978 data
361	Paint Facility	Perchloroethylene					5.92E+00					Calculated value from 1987/1989 AEI; assume contaminant is Perc (based on volume of emission)	
365	Paint Shop Hangar	Methylene Chloride			164.50		2.60E+02					Calculated value from 1987/1989 AEI	
		Chromic Acid			0.10		8.09E-07					Assume 10 CFM emission volume	
		Toluene			44.00		3.42E-04					Assume chemical is toluene from paint	
		Methyl Ethyl Ketone			31.79		4.10E+01					Assume 10 CFM emission volume	Assume 100 CFM volume emission; 1973 data
		Perchloroethylene			1.05		8.15E-06					Assume 10 CFM emission volume	
375	Welding shop/paint/degrease	Methyl Ethyl Ketone	32.05 gal/mo				1.33E+00					Assume 100% volatilization; 1969 data	
		Chromic Acid	13.5 gal/mo				4.55E-02					Assume 0.1% overspray; 1969 data	
		Methylene Chloride	1 gal/mo				6.65E-02					Assume 100% volatilization; 1968 data	
		Toluene	27.05 gal/mo				1.12E+00					Assume 100% volatilization; 1969 data	
		Perchloroethylene	22.5 gal/mo				4.55E-01					Assume 25% volatilization; 1968 data	
		Benzene											
385	Paint stripping	Methyl Ethyl Ketone					5.10E+01					Calculated value from 1987 AEI	Assume 100 CFM volume emission; 1979 data
645	Zinc Chromate Priming	Chromic Acid			0.06		5.01E-07					Assume 10 CFM emission volume	
		Methyl Ethyl Ketone	3 gal/yr				1.01E-02					Assume 100% volatilization	
647	General Usage	Toluene	3.6 gal/mo				1.50E-01					Assume 100% volatilization	
920	Solvent Tank	Perchloroethylene					3.00E-01					Assume solvent tank contains perc	
1420	Special Weapons	Chromic Acid											Assume 100 CFM volume emission; 1971 data
3020	Coatings	Chromic Acid											Assume 100 CFM volume emission; 1973 data

General Emissions, 1985 Data/Building Number Unknown	Summary of estimated 1980a emissions	Summary of estimated 1970a emissions
