NOTICES

This report is not to be construed as an official Department of the Army position.

Mention of any trade names or manufacturers in this report shall not be construed as an official endorsement or approval of such products or companies by the U. S. Government.

Destroy this report when it is no longer needed. Do not return it to the originator.

APPENDIX A

TECHNOLOGY SURVEY SUMMARY

Appendix A Technology Survey Summary

A.1 Technology Report

As required by contract DAAE07-84-C-R017, a comprehensive technology survey report was prepared between February and August 1984. This report details the approach and results of a survey of motors, solid-state controls, alternator/generators, and servo components which were potential candidates for the advanced electric drive study. In addition, solid-state components and various materials such as advanced magnetics were included in the survey. The survey report was approved in January 1985.

A.2 Survey Update

The motor tree at Figure A.2-1 formed the basis for the motor survey. Results of the survey effort for motor selection is shown in Figure A.2-2. This selection process was the result of an extensive matrix/tradeoff analysis and was initially used in early concept development. As the concepts were refined, performance vehicle factors became an influence in the motor component selection. The result of the influence was the selection of the Homopolar motor for the DC system and the high frequency induction motor for the AC system. The selection of these motors for the Configuration I analysis dictated the additional system components such as the motor power conditioners/controllers and the alternator/generators.

Figure A.2-3 compares the selected motors with respect to operational and characteristic attributes. The hybrid permanent magnet (PM) "brushless" motor is included in the comparison to indicate the effect of relative complexity introduced by the total PM motor/power conditioner system. In this comparison, the DC and AC motors operate independent of an external power conditioner.

It is apparent for this update comparison that no clear "best" motor component selection is possible since each different type has certain advantages not shared by the other.

Motor power controllers/conditioners are compared in Figure A.2-4. In this comparison, the DC system appears to have some advantage due to the inherent gain of the DC motor and thus the lack of any power semiconductors. The power controllers/conditioners for the AC and hybrid motors are all DC to AC inverter systems and are designed around large power semiconductors.

A comparison of selected alternator and generator technologies is shown in figure A.2-5. In this comparison, the AC alternator candidate is a standard aircraft design with an operating frequency of 400 Hz.

The present status of candidate power semiconductors is shown in Figure A.2-6. As expected, the semiconductor industry continues

to work on improvements to increase the voltage and current capability and reduce the turn-on/turn-off time. No significant technology break-through's are presently foreseen in this area which would produce a radical improvement for use in high power drive systems.

It is unfortunate that the majority of high power semiconductor research is being done outside the United States.

Figure A.2-7 documents the trend in magnetic materials used in permanent magnet motors. With the introduction of Neodymium/Iron/Boron, an alternative is not available to replace, Smarium-Cobalt magnets for high energy density applications. Neodymium/Iron/Boron will continue to be improved and should be seen in products within the next 3 to 5 years. The use of this new material should yield a significant weight reduction and associated cost reduction in motors and generators.

APPENDIX B

DATA GENERATION REPORTS

B.1 Analytical Methods Used For Performance Analysis

Our performance analysis used validated computer programs to evaluate all significant factors when preparing performance predictions. Existing programs were adapted to meet the specific analysis requirements of this project. These existing programs were based on the principles of SAE recommended practice J688, with appropriate modifications for tracked vehicles. The resulting programs produced the following specified data:

1. Tractive effort vs. speed

2. Acceleration

3. Startability on grades

4. Maximum speed on grades

5. Minimum turn radius vs. speed

The programs were integrated on a conservation of energy basis:

[1] (Input HP - Loss HP) * (Drive efficiency) = Power output

The input horsepower is the engine horsepower at its operating speed less the appropriate deductions for altitude, temperature, air cleaner, muffler and grills. The loss horsepower includes such items as cooling fan, auxiliary generator, hydraulic pumps and similar parasitic loads. The drive efficiency is measured from engine flywheel to sprocket to fairly assess added losses due to speed up transfer cases to drive high speed generators or high ratio final drives to match high speed motors. The power output to rolling resistance, windage (air resistance), grade resistance and turning losses.

The power budget for the input horsepower is as follows:

1.	Rated engine horsepower	500.0
2.	Conditions (standard)	- 0.0
3.	Air cleaner & muffler	- 5.0
	Net input horsepower----------	495.0

The power budget for parasitic losses is as follows:

1.	Net input horsepower	495.0
2.	Fan (sized for ballistic grills)	-46.2
3.	Auxiliary generator	- 5.8
4.	Hydraulic pump	- 3.0
	Net input horsepower	440.0

The drive efficiency is determined as follows:

1. Generator (or alternator) efficiency is estimated from data for similar items and from manufacturer's estimates. Since these efficiencies are essentially constant at loads over 25% of rating, and the analysis is for full power, a fixed efficiency value is used for all calculations for any given generator type.

2. Power conditioning and control equipment, like the generator, have essentially constant efficiency under normal loads and are therefore also held at a fixed value that is based on data for similar items and on manufacturer's estimates.

3. Motor efficiencies under normal loads are primarily a function of armature speed (RPM). Curve fits have been made with correlation coefficients of at least 0.99 and the resulting equations are used to calculate the efficiency of each motor at each operating point of every operating condition. This detailed approach becomes particularly significant in turns, when each motor has its own individual efficiency at each operating point. Refer to Section 5.1.4.6, Figure 5.1.4.6-B for an example of the differentiations between systems that result from this precise analysis.

4. Power output must equal the sum rolling resistance, wind resistance, grade resistance and turn losses so steady state operation can exist. These values are determined as follows:

o Rolling resistance:

Rolling resistance has been based on a value of 100 pounds per ton, which has been found to be a reasonable value for tracked vehicles on smooth, hard surfaces.

[2] $RR = GVW / 2000 * Cr$

Where:

RR = Rolling resistance in pounds
GVW = Gross veicle weight
Cr = Rolling resistance coefficient
(100 pounds per ton for this study)

o Wind resistance:

Wind resistance has been based on the specified frontal area, a drag coefficient (Cd) of 1.0, vehicle speed in MPH, and a coefficient of 1/391 for standard conditions (ref. Fluid Dynamic Drag, Dr.-Ing. Sighard Hoerner).

These values are used as follows:

[3] $Rw = Af * Cd * (MPH \hat{} 2) / 391$

Where:

Af = Frontal area in square feet
Cd = Drag coefficient (estimated at 1.0)
MPH = Vehicle speed, miles per hour

o Grade resistance:

Grade resistance is calculated from the basic geometric considerations. The equation used is:

[4] $Rg = GVW * Sin (Atn (GR / 100)$

Where:

Rg = Grade resistance in pounds
GVW = Gross vehicle weight in pounds
GR = Grade in per cent

o Turning losses:

Turning losses consist of power dissipated in scrubbing the tracks around a turn and regeneration losses due to inefficiencies in the regeneration system. These values of scrub horsepower and regenerative horsepower are quantified using methods originated by Merritt and updated in TACOM Technical Report 10969,"Investigation of the Factors Involved in Steering Tracklaying Vehicles". As the method is complex, reference to this report is recommended for those who want the details of the analytical method. The "Scrub Horsepower" is applied directly as a loss. The regeneration loss is found by first determining regeneration efficiency from motor speed and controller efficiency, as is described for drive efficiency. The Transfer Horsepower is then multiplied by the regeneration efficiency to determine the losses due to regeneration.

The above analytical methods have been integrated into a series of programs to solve for specific operating conditions such as tractive effort vs. speed, speed vs. time, speed vs. distance, maximum speed vs. grade, and minimum turning radius vs. speed. In each case the complexity of the calculation necessitates an iterative solution. The appropriate variable is increased until a power balance is reached and the requirements of equation [1] above are met. The performance and load values for that

particular operating point are then printed as required by the contract.

B.2 Data Table Description

The tables in Appendix B provide detailed quantification of the results discussed in the report and the power train load and speed data required by the contract. The following tables tabulate the performance analysis data used in this report. Tables are organized to facilitate comparative analysis by grouping by type of performance, and presenting data for all of the various vehicle and drive types within that group. The data table groups are:

A. Speed vs. grade and tractive effort

B. Acceleration

C. Sprocket and motor speeds and loads for maximum turn condition

D. Gear speeds and loads at maximum turn condition

E. Gear speeds and loads at maximum tractive effort condition

Within these groups are performance results for the following vehicle and drive types:

1. 19.5 ton, Configuration I, AC induction motor drive system

2. 19.5 ton, Configuration II. AC induction motor system

3. 19.5 ton, Configuration I, DC homopolar system

4. 40 ton, Configuration I, AC induction motor drive system

5. 40 ton, Configuration II, AC induction motor drive system

6. 40 ton, Configuration I, DC homopolar system

Tables can be easily located by combining the heading letters and numbers from the above listings. As an example, acceleration data for the 19.5 ton, Configuration II, AC induction system is in table B-2.

B.2.A Speed Vs Grade And Tractive Effort Tables

The following tables provide speed vs. grade data plus corresponding sprocket speeds and torques. They are divided into three sections consisting of Title Heading, Data Input and Results. The Title Heading provides in addition to the title, traceability data of program authors, revision data and run date.

The data input section inputs general vehicle description parameters plus operational assumptions such as:

1. Maximum speed: A value of 45 MPH has been used as a contract requirement.

2. Drag coefficient: A value of 1.0 has been used as a reasonable, yet conservative value throughout this study.

3. Rolling resistance: A value of 100 pounds per ton has been used to represent operation on a smooth, hard surface.

4. Engine gross horsepower: Values of 500 and 1000 have been used for the 19.5 and 40 ton vehicles respectively as directed by the contract.

5. Engine loss horsepower: Values of 60 and 120 have been used for the 19.5 and 40 ton vehicles respectively. See Section A.II.1 for a sample loss budget.

The results section of these tables provide the following data:

1. Grade (%): Increments have been selected to provide the range of data specified in the contract.

2. Speed (MPH): This is the maximum speed the vehicle can maintain on the specified grade.

3. Resistance (Pounds): This is the resistance encountered when operating at the stated speed on the stated grade and equals the tractive effort at this limiting condition.

4. Sprocket Torque and RPM: These data can be used to calculate torques and speeds required in related drive-train components.

B.2.B Acceleration Tables

The following tables provide acceleration data consisting of time, tractive effort, speed, distance and sprocket RPM, torque and horsepower. These tables are divided into three sections consisting of the Title Heading, Data Input and Results. The Title Heading provides in addition to the subject, traceability data of program author, operator, purpose, revision date and run date.

The Data Input section inputs general vehicle description parameters plus operational assumptions such as:

1. Coefficient of drag: a value of 1.0 has been used as a reasonable, yet conservative value throughout this study. This coefficient is multiplied by the frontal area and the velocity head to provide air resistance.

2. Rolling resistance: a value of 100 pounds per ton has been used to represent operation on a smooth, hard surface. This value is multiplied by the gross vehicle weight in tons to obtain vehicle rolling resistance.

3. Coefficient of friction: a value of 0.7 has been used to represent the contact between the track and the roadway. This is used to limit the maximum possible acceleration to the value that the selected adhesive condition will allow.

4. Mass increment for rotation: This value has been calculated from the motor and gear train data. It is input as a fraction of the translational mass of the vehicle. In the calculations, the translational mass of the vehicle is increased by this amount to correct for the rotational inertia of the system.

5. Grade, %: This value is determined by the operating situation. Most calculations have used level (0%), but it was also used to confirm starting performance on a 60% grade.

The results section provides the following acceleration data:

1. Time (seconds): This is cumulative time from the start of the run. As directed by the contract, no allowance is made for throttle response time.

2. Net tractive effort (pounds): This shows the tractive effort available at the corresponding time. It can be either power or adhesion limited.

3. Speed (MPH): This is the instantaneous speed at the given time.

4. Distance (feet): This is the cumulative distance from the start of the run.

5. Sprocket RPM, LB-FT, and HP: These data can be used to calculate speeds, torques and powers required in the related drive train components.

B.2.C Maximum Turn Conditions

The following tables provide drivetrain dat for a vehicle in a turn. These tables are divided into three sections consisting of Title Heading, Data Input and Results. The Title Heading provides in addition to the title, traceability data of program authors, revision data and run date.

The data input section is generally similar to the previous sections except that an input titled "Maximum Acceleration" has been added. This input is the maximum lateral acceleration that the vehicle is to develop in a turn. For this study, a value of 0.5 has been used as representative of aggressive but not reckless driving.

The Results section provides the following data:

1. Vehicle speed in 1.5 MPH increments to 45 MPH.

2. Lateral acceleration in G's, limited either by available power or by the selected maximum.

3. Turn radius in feet measured to the centerline of the vehicle.

4. Data for inner and outer sprockets is presented in four columns each as follows:

   a. Apparent horsepower is the combined power at the sprocket and is the value that would be determined by use of a torque meter and RPM counter.

   b. Propulsion horsepower is the fraction of the apparent power that is used to propel the vehicle.

   c. Sprocket RPM with a negative sign indicates reverse rotation.

   d. Sprocket torque with a negative sign indicates a retarding rather than driving torque.

5. Scrub horsepower is the power loss due to scrubbing the tracks around a turn and power flow is always from the vehicle to the tracks.

6. Transfer horsepower is the regenerated power that enters the inner sprocket, is transferred by the drive train to the outer sprocket.

B.2.D Gear Speeds And Loads at Maximum Turn Conditions

The following tables provide the torque and speed data for all gears during maximum turn conditions. These tables are divided into the same three divisions as the previous tables. The Title Heading and the inputs are the same as the previous section. The data format facilitates analysis by placing speeds and torques of each component in adjacent positions.

The first row of the results section lists the components by name or by identification letter shown on the gear configuration diagrams. The next segment defines the data arrangement; typically RPM above a dotted line and torque in pound-feet immediately below. The data output is immediately below, with horizontal dotted lines for each 1.5 MPH increment, and corresponding and speeds and torques above and below the dotted line.

GEAR LOADS AT MAXIMUM TURN CONDITION BY: RICK LEWIS; REVISION: 16-JUL-85
RUN DATE: 20-AUG-85;5

INPUT DATA:

GROSS VEHICLE WEIGHT, tons = 19.5
MAXIMUM VELOCITY, mph = 45.0
ENGINE GROSS HP. = 500.0
LOSS ENGINE HP. = 60.0
FRONTAL AREA, ft^2 = 57.0
TREAD WIDTH, in. = 92.5
TRACK LENGTH, in. = 150.0
TRACK PITCH, in. = 6.03
NUMBER OF SPROCKET TEETH = 11
ROLLING RESISTANCE,lb per ton= 100.0
GRADE, % = 0.0
COEFFICIENT OF FRICTION = 0.70
MAXIMUM ACCELERATION, gs =0.50
COEFICIENT OF DRAG = 1.00

GEAR LOADS AT MAXIMUM TURN CONDITION BY: RICK LEWIS: REVISION: 16-JUL-85
RUN DATE: 7-AUG-85;4

INPUT DATA:

GROSS VEHICLE WEIGHT, tons = 19.5 | TREAD WIDTH, in. = 92.5 | GRADE, % = 0.0
MAXIMUM VELOCITY, mph = 45.0 | TRACK LENGTH, in. = 150.0 | COEFFICIENT OF FRICTION = 0.70
ENGINE GROSS HP. = 500.0 | TRACK PITCH, in. = 6.03 | MAXIMUM ACCELERATION, gs =0.50
LOSS ENGINE HP. = 60.0 | NUMBER OF SPROCKET TEETH = 11 | COEFICIENT OF DRAG = 1.00
FRONTAL AREA, ft^2 = 57.0 | ROLLING RESISTANCE,lb per ton= 100.0

GEAR LOADS AT MAXIMUM TURN CONDITION BY: RICK LEWIS; REVISION: 16-JUL-85
RUN DATE: 20-AUG-85;112

INPUT DATA:

GROSS VEHICLE WEIGHT, tons = 40.0
MAXIMUM VELOCITY, mph = 45.0
ENGINE GROSS HP. =1000.0
LOSS ENGINE HP. = 120.0
FRONTAL AREA, ft^2 = 68.3
TREAD WIDTH, in. = 109.8
TRACK LENGTH, in. = 183.1
TRACK PITCH, in. = 7.63
NUMBER OF SPROCKET TEETH = 11
ROLLING RESISTANCE,lb per ton= 100.0
GRADE, % = 0.0
COEFFICIENT OF FRICTION = 0.70
MAXIMUM ACCELERATION, gs =0.50
COEFICIENT OF DRAG = 1.00

Efficiency data for Westinghouse induction motor by Craig Joseph 10-MAY-85

GEAR LOADS AT MAXIMUM TURN CONDITION BY: RICK LEWIS; REVISION: 16-JUL-85
RUN DATE: 15-AUG-85:111

INPUT DATA:

GROSS VEHICLE WEIGHT, tons = 40.0
MAXIMUM VELOCITY, mph = 45.0
ENGINE GROSS HP. =1000.0
LOSS ENGINE HP. = 120.0
FRONTAL AREA, ft^2 = 68.3
TREAD WIDTH, in. = 109.8
TRACK LENGTH, in. = 183.1
TRACK PITCH, in. = 7.63
NUMBER OF SPROCKET TEETH = 11
ROLLING RESISTANCE, lb per ton= 100.0
GRADE, % = 0.0
COEFFICIENT OF FRICTION = 0.70
MAXIMUM ACCELERATION, gs =0.50
COEFICIENT OF DRAG = 1.00

Efficiency data for Homopolar motor

B.2.E Maximum Power Gear Loads And Speeds

These tables are identical to those of Appendix Section B.2.D except that they are for the full range of specified speed vs tractive effort. Refer to Section B.2.D if a detailed explanation of the data sheets is needed.

GEAR LOADS DURING MAXIMUM TRACTIVE EFFORT CONDITION BY: RICK LEWIS; REVISION: 8-JUN-85
RUN DATE: 20-AUG-85;8

INPUT DATA:

GROSS VEHICLE WEIGHT, tons = 19.5 MAXIMUM VELOCITY, mph. = 45.0 ENGINE NET HP. = 440.0
TRACK PITCH, in. = 6.03 NUMBER OF SPROCKET TEETH = 11

Efficiency data for Westinghouse induction motor by Craig Joseph 10-MAY-85

GEAR LOADS DURING MAXIMUM TRACTIVE EFFORT CONDITION — BY: RICK LEWIS; REVISION: 8-JUN-85
RUN DATE: 14-AUG-85;108

INPUT DATA:

GROSS VEHICLE WEIGHT, tons = 40.0 MAXIMUM VELOCITY, mph = 45.0 ENGINE NET HP. = 880.0
TRACK PITCH, in. = 7.63 NUMBER OF SPROCKET TEETH = 11

Efficiency data for Homopolar motor * CONFIGURATION I
by Gene Siedler 20-MAY-85 * TWIN DRIVE MOTOR SET-UP

B.3 Regeneration In Steering

The effects of regeneration efficiency on steering performance were studied to quantify significance on this factor. The following curves illustrate the results of this study. The 19.5 ton vehicle parameters were used. The propulsive efficiency of the drive was based on the homopolar system, which is only slightly lower than the induction motor systems. Regeneration efficiency was varied as noted to determine the effects.

1. Figure B.3-1: These curves show that regeneration efficiencies of 60% or better will provide the same minimum turn radius.

2. Figure B.3-2: These curves show that regeneration efficiencies of 60% or better will provide the 0.5 G. lateral acceleration that is desirable for evasive maneuvers.

3. Figure B.3-3: These curves show that power requirements in turns decreases with improved regeneration efficiency, which will reduce fuel consumption.

4. Figure B.3-4: These curves show that improved regeneration efficiency increases outer sprocket maximum loads, potentially increasing the required size of motors and related gearing.

5. Figure B.3-5: These curves show that regeneration horsepower is constant with regeneration efficiencies of 60% or greater.

6. Figure B.3-6: These curves show regeneration efficiency indirectly changes scrub horsepower due to more scrubbing in the sharper turn.

7. Figure B.3-7: These curves show the effect of sharper turns on regenerated horsepower at 90% regeneration efficiency and that the resulting higher powers impose greater loads on system components.

The conclusion from the data provided by these curves was that regeneration efficiencies of 60% or better would provide satisfactory performance. Since all recommended drives provided the desired level of regeneration efficiency, this characteristic did not become a factor for discriminating between the various drives.

B.4 Impact Of Grades On Motor Loads While Steering

Data for turns on grades was evaluated and found to produce high momentary loads that are within the thermal limits of the drive components. Two curve sets were produced to investigate alternate operational assumptions.

The first set (Figure B.4-1) are titled "Grade vs. Maximum Sprocket HP & RPM". These curves plot the speeds and loads for the highest horsepowers and RPM that are theoretically possible. The power inputs from the ground (indicated as horsepower) become very high under certain conditions. The implied operation that produced these results cover some areas that are unrealistic combinations of speed, grade and turn radius. It is considered unlikely that a driver will make the sharpest possible turn, at maximum speed on the steepest downgrade.

The second set of curves (Figure B.4-2) titled "Grade vs. Maximum Sprocket HP & RPM (LTD)" represent a more limited operational envelope. Downhill speeds are limited to the speeds that the vehicle can achieve on upgrades. These curves are considered representative of a prudent driver under normal operating conditions.

All points on the "LTD" curve are easily within the momentary overload capacity of the drives, which is considered reasonable for turning requirements. Downgrades steeper than 40% impose excessive loads at maximum 45 MPH speed, but operation at this combination of grade and speed is considered unrealistic. It was therefore concluded that normal turns on grades could present no peculiar load problems for the recommended electric drive systems.

B.5 Downhill Steering Limit

Limited available power while coasting downhill can limit steering control. When operating on moderate downgrades, the engine can at times be operating near idle condition. Steering reactions can then be limited by power available. This condition is encountered with mechanically driven tracked vehicles and it is necessary for the drive to give the engine added throttle to obtain normal steering response. Since it is instinctive to turn and apply brakes to avoid an obstacle, special driver training is required to assure proper response. The results of the studies on this subject are shown on the following curves and their data sheets.

1. Figure B.5-1: These curves show a typical power distribution for maximum turn going down a moderate grade.

2. Figure B.5-2: These curves replot the same data as Figure B.5-1, but a summation curve "Engine + Both Sprockets" is shown. At points near 20 MPH the net power barely covers system losses.

3. Figure B.5-3: These curves show that below 20 MPH decreased net engine power degrades steering ability.

4. Figure B.5-4 and B.5-5: These curves plot the same data with different scales for better legibility. They show that steering ability is limited up to 25 MPH.

Acceleration analysis was made for the 60% grade starts and the results are shown in Figures 5.2.6.4-1. These curves show positive starts that promptly reach grade limited speed.

B.6 A-C Induction Motor Drive System Electrical States

A detailed analysis of the oeprating states of all components was made to assure that all components were operating within normal rated limits. The results are given in the following tables:

1. 19.5 Ton, Configuration I
2. 19.5 Ton, Configuration II
3. 40.0 Ton, Configuration I
4. 40.0 Ton, Configuration II

The voltage, current and frequencies values have been given vs. vehicle speed to illustrate the operational characteristics. These tables confirmed that there were no peculiar operating points to cause failure of the components.

B.7 Homopolar Motor Drive System Electrical States

A detailed analysis of the operating states of all components was made to assure that they were operating within normal rated limits. The results are given in the following tables:

1. 19.5 Ton, Configuration I

2. 40.0 Ton, Configuration I

The voltage and current values have been given tabulated vs. vehicle speed to illustrate the operational characteristics. These tables confirmed that there were no peculiar operating points to cause failure of the components.

ELECTRIC VEHICLE MISSION SIMULATION

DC HOMOPOLAR MOTOR DRIVE SYSTEM
19.5 TON

FMC / NORTHERN ORDNANCE DIVISION
MINNEAPOLIS, MINNESOTA USA

REVISION DATE: 06/05/85
RUN DATE: 08-22-1985

ELECTRICALLY DRIVEN, TRACKED VEHICLE PERFORMANCE IS SIMULATED BY THIS PROGRAM. DETAILED ASPECTS OF VEHICLE PERFORMANCE CAN BE INVESTIGATED USING THE FOUR RESIDENT SUB-PROGRAMS LISTED BELOW. THE SUB-PROGRAM IN USE IS IDENTIFIED WITH AN ASTERISK.

* 1.)	ELECTRIC DRIVE PERFORMANCE –	STEADY STATE VEHICLE PERFORMANCE ANALYSIS WITH DETAILED EMPHASIS ON ELECTRIC POWER DRIVE PARAMETERS. ENERGY USAGE, HEAT REJECTION, AND FUEL IMPACT ARE ALSO CALCULATED.
2.)	VEHICLE ACCELERATION PERFORMANCE –	DYNAMIC VEHICLE PERFORMANCE ANALYSIS WHICH REALISTICALLY SIMULATES GROSS VEHICLE MISSION OVER ALL TERRAIN CONDITIONS. ACCELERATION, DECELERATION, BRAKING AND CONSTANT VELOCITY CONDITIONS ARE CONSIDERED.
3.)	ACCELERATION DYNAMICS ROUTINE –	DETAILED ANALYSIS OF FULL POWER VEHICLE ACCELERATION DURING TURNING AND NON-TURNING MANEUVERS ON USER SELECTED GRADES AND SURFACES. INCREMENTAL DYNAMIC PARAMETERS ARE GENERATED AND TABULATED.
4.)	REDUCTION DYNAMICS ROUTINE –	DETAILED ANALYSIS OF SPEED/TORQUE LOADING OF ALL VEHICLE POWER TRAIN REDUCTION ELEMENTS. FINAL SPROCKET DRIVES AND DIESEL ENGINE INTERFACE ARE INCLUDED IN ANALYSIS.

MAX. LAT. ACCEL., g's= .5

VEHICLE DATA

GROSS VEHICLE WEIGHT, tons= 19.5

FRONTAL AREA, sq. ft.= 57

COEFFICIENT OF DRAG= 1

TREAD WIDTH, in.= 92.5

TRACK LENGTH, in.= 150

TRACK PITCH, in.= 6.03

NUMBER OF SPROCKET TEETH= 11

ROLLING RESISTANCE, lb. per ton= 100

MAXIMUM VELOCITY, mph= 45

ENGINE DATA

ENGINE: VTA-903

MAX. POWER, hp= 500

MAX. SPEED, rpm= 2960

SPEED FOR MIN. FUEL, rpm= 2100

COOLING LOSSES, % Ghp= 4

INLET/EXHAUST LOSSES, % Ghp= 1.5

AUXILIARY POWER hp= 6

FUEL CAPACITY, gal.= 175

SCHEDULING: CONSTANT

ELECTRIC DRIVE DATA

TYPE: HoPol P-G

PEAK MOTOR EFF., %= 90

GENERATOR EFF., %= .92

MOTOR KM V/Krpm-A= .005

GEN. KG, V/Krpm-A= .005

ELECTRIC DRIVE PERFORMANCE

ELECTRIC VEHICLE MISSION SIMULATION

DC Homopolar Motor Drive System
40.0 TON

FMC / NORTHERN ORDNANCE DIVISION
MINNEAPOLIS, MINNESOTA USA

REVISION DATE: 06/05/85
RUN DATE: 08-22-1985

ELECTRICALLY DRIVEN, TRACKED VEHICLE PERFORMANCE IS SIMULATED BY THIS PROGRAM. DETAILED ASPECTS OF VEHICLE PERFORMANCE CAN BE INVESTIGATED USING THE FOUR RESIDENT SUB-PROGRAMS LISTED BELOW. THE SUB-PROGRAM IN USE IS IDENTIFIED WITH AN ASTERISK.

* 1.) ELECTRIC DRIVE PERFORMANCE - STEADY STATE VEHICLE PERFORMANCE ANALYSIS WITH DETAILED EMPHASIS ON ELECTRIC POWER DRIVE PARAMETERS. ENERGY USAGE, HEAT REJECTION, AND FUEL IMPACT ARE ALSO CALCULATED.

2.) VEHICLE ACCELERATION PERFORMANCE - DYNAMIC VEHICLE PERFORMANCE ANALYSIS WHICH REALISTICALLY SIMULATES GROSS VEHICLE MISSION OVER ALL TERRAIN CONDITIONS. ACCELERATION, DECELERATION, BRAKING AND CONSTANT VELOCITY CONDITIONS ARE CONSIDERED.

3.) ACCELERATION DYNAMICS ROUTINE - DETAILED ANALYSIS OF FULL POWER VEHICLE ACCELERATION DURING TURNING AND NON-TURNING MANEUVERS ON USER SELECTED GRADES AND SURFACES. INCREMENTAL DYNAMIC PARAMETERS ARE GENERATED AND TABULATED.

4.) REDUCTION DYNAMICS ROUTINE - DETAILED ANALYSIS OF SPEED/TORQUE LOADING OF ALL VEHICLE POWER TRAIN REDUCTION ELEMENTS. FINAL SPROCKET DRIVES AND DIESEL ENGINE INTERFACE ARE INCLUDED IN ANALYSIS.

COURSE DATA

COURSE: DATA INPUT BY USER

SURFACE: COMPACTED SOIL

COEFFICIENT OF FRICTION= .7

PERFORMANCE LIMITS

MAX. COURSE VELOCITY, mph= 45

MAX. LAT. ACCEL., g's= .5

VEHICLE DATA

GROSS VEHICLE WEIGHT, tons= 40.0

FRONTAL AREA, sq. ft.= 68.25

COEFFICIENT OF DRAG= 1

TREAD WIDTH, in.= 109.84

TRACK LENGTH, in.= 183.07

TRACK PITCH, in.= 7.625

NUMBER OF SPROCKET TEETH= 11

ROLLING RESISTANCE, lb. per ton= 100

MAXIMUM VELOCITY, mph= 45

ENGINE DATA

ENGINE: AD-1000

MAX. POWER, hp= 1000

MAX. SPEED, rpm= 3725

SPEED FOR MIN. FUEL, rpm= 2400

COOLING LOSSES, % Ghp= 4

INLET/EXHAUST LOSSES, % Ghp= 1.5

AUXILIARY POWER hp= 12

FUEL CAPACITY, gal.= 350

SCHEDULING: CONSTANT

ELECTRIC DRIVE DATA

TYPE: HoPol P-G

PEAK MOTOR EFF., %= 90

GENERATOR EFF., %= .92

MOTOR KM V/Krpm-A= .005

GEN. KG, V/Krpm-A= .005

APPENDIX C

CONFIGURATION III ANALYSIS

Title: CONFIGURATION III ANALYSIS

1. INTRODUCTION

FOR THE PURPOSE OF THIS ANALYSIS THE FINAL DRIVES ARE ASSUMED TO BE A CONVENTIONAL ARRANGEMENT OF SPUR REDUCTION GEARS COMBINED WITH A PLANETARY SECTION TO SUM THE PROPULSION AND STEER INPUTS.

THE APPROACH USED IS AS FOLLOWS:

- BRIEF DISCUSSION OF CONFIGURATION III
- GEAR AND POWER FLOW ANALYSIS

2. DISCUSSION OF CONFIGURATION III

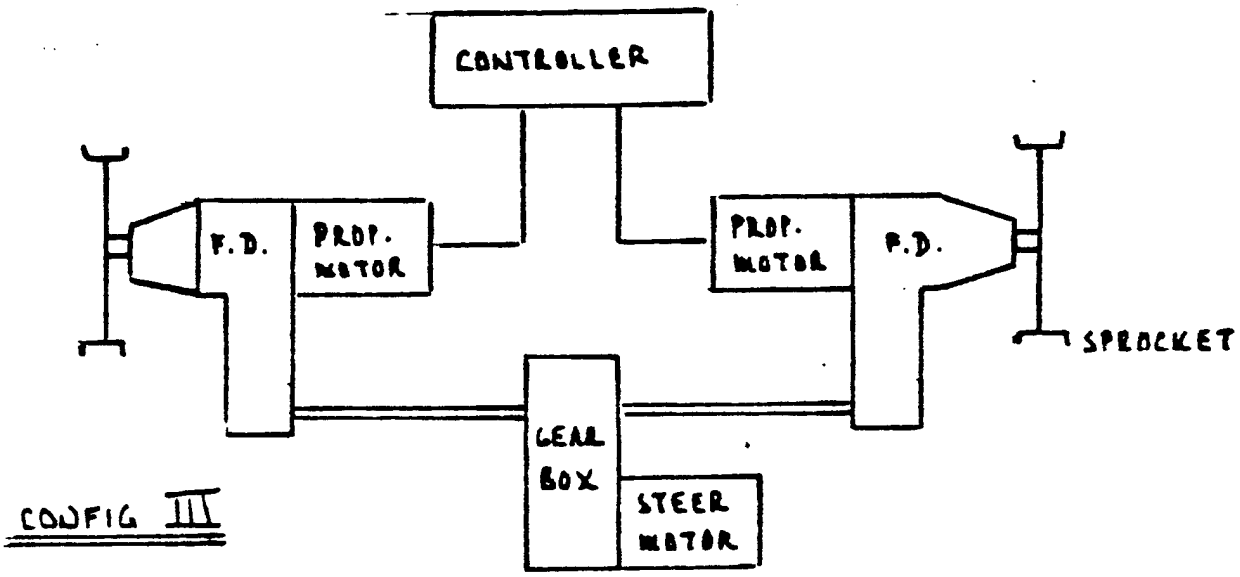
IN ORDER FOR CONFIGURATION III TO FUNCTION :

a) BOTH PROPULSION MOTORS MUST OPERATE AT IDENTICAL SPEEDS AND THUS CONTROL THE AVERAGE VEHICLE SPEED.

b) THE STEER MOTOR CONTROLS STEERING ONLY.

c) THE FINAL DRIVES MUST HAVE SOME TYPE OF COMBINING PLANETARY.

A SKETCH OF THIS CONFIGURATION APPEARS BELOW :



CONFIG III

3. GEAR AND POWER FLOW ANALYSIS

THE FOLLOWING ANALYSIS IS TYPICAL FOR A PLANETARY GEAR SET BASED ON MATHEMATICAL PROCEDURES AND PLANETARY GEAR SET OPERATION.

a) ASSUMPTIONS / BACKGROUND :

SYMBOLS USED

T ≡ TORQUE

ω ≡ ANGULAR VELOCITY

N ≡ NO. OF TEETH

SUBSCRIPTS

S = SUN GEAR

I = INTERNAL GEAR

C = CAGE

SIGN CONVENTION

INPUT HP = + , OUTPUT HP = −

∴ INPUT SPEED AND TORQUE WILL HAVE THE SAME SIGN AND OUTPUT SPEED AND TORQUE WILL HAVE OPPOSITE SIGN. $\Sigma T = 0$. (PROOF @ P. C-10)

TORQUE RELATIONSHIP

$$T_S = -\frac{T_C}{1+M} \qquad \text{WHERE } M = \frac{N_I}{N_S}$$

$$T_I = -\frac{M}{1+M} T_C \qquad \therefore T_S + T_I = -T_C$$

b) ARRANGEMENT OF COMBINING PLANETARY :

TWO ARRANGEMENTS WERE ANALYZED AS FOLLOWS

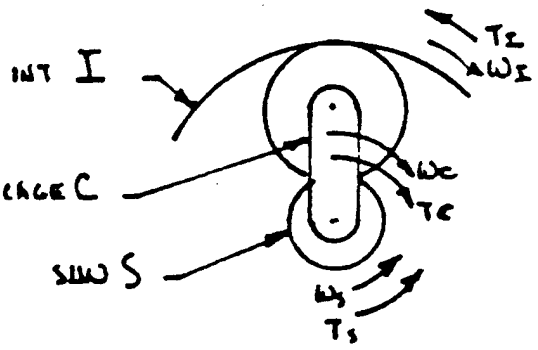
	# 1	# 2
CAGE	OUTPUT	
INTERNAL GEAR	PROP. MOTOR	STEER MOTOR
SUN GEAR	STEER MOTOR	PROP. MOTOR

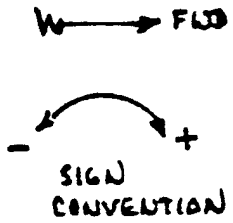
ANALYSIS OF THESE ARRANGEMENTS PROVIDE THE BACKGROUND FROM WHICH CONFIGURATION III POWER FLOW ANALYSIS CAN BE DERIVED. ARRANGEMENT #1 IS ANALYZED FIRST FOR GEARING AND POWER FLOW; THEN ARRANGEMENT #2.

d) ARRANGEMENT #1 (INTERNAL = PROP. MOTOR, SUN = STEER MOTOR, CAGE = OUTPUT)

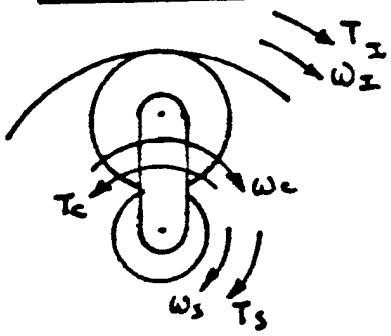
GEARING

SIDE DRIVING INNER TRACK





SIDE DRIVING OUTER TRACK



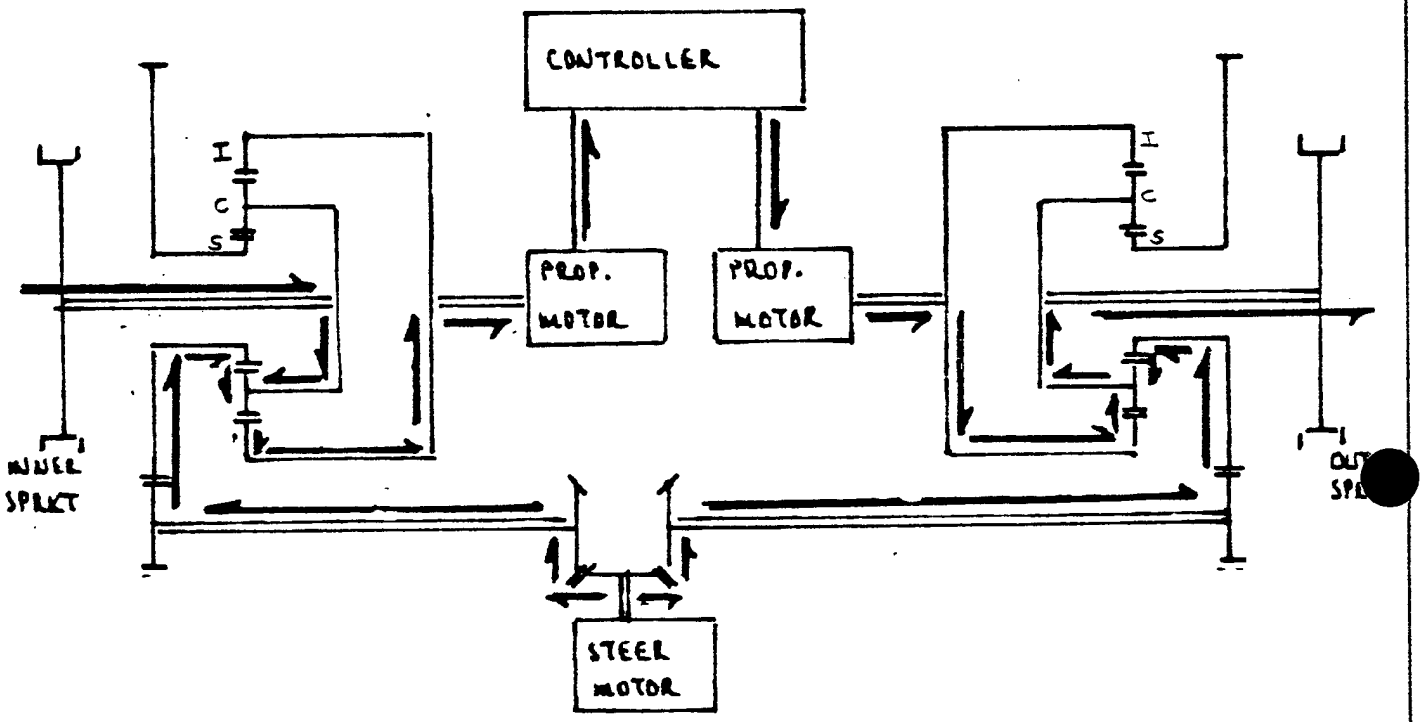
- SINCE THE SUN GEARS ARE DRIVEN BY THE STEER MOTOR, THEY MUST HAVE OPPOSING SPEEDS AS SHOWN ABOVE TO SLOW DOWN INNER TRACK AND SPEED UP OUTER TRACK.
- BY DEFINITION (PAGE 3) AT THE INNER TRACK SIDE, T_c & ω_c ARE SAME SIGN (BECAUSE OF REGENERATIVE HP FLOWING INTO UNIT FROM TRACKS). AT OUTER TRACK SIDE, THE SIGNS OPPOSE BECAUSE HP IS FLOWING OUT OF UNIT.
- FROM TORQUE RELATIONSHIP (PAGE 3), BOTH SUN TORQUE, T_s & INTERNAL GEAR TORQUE, T_I MUST BE OF OPPOSITE SIGN FROM CAGE TORQUE, T_c, SHOWN ABOVE.
- THE SIGNS OF SPEED, ω; TORQUE, T & ; HP WILL THEN BE :

	INNER TRACK			OUTER TRACK		
	I	S	C	I	S	C
	PROP MOTOR	STEER MOTOR	OUTPUT	PROP MOTOR	STEER MOTOR	OUTPUT
ω	+	−	+	+	+	+
T	−	−	+	+	+	−
▲ HP	−	+	+	+	+	−

▲ SEE SIGN CONVENTION PREVIOUS PAGE : − = OUT , + = IN

POWER FLOW SCHEMATIC

REGENERATIVE HP FLOWS INTO THE PROPULSION MOTOR AND NOT THROUGH THE STEER CONTROL SHAFT.



FORWARD

STEER DIRECTION

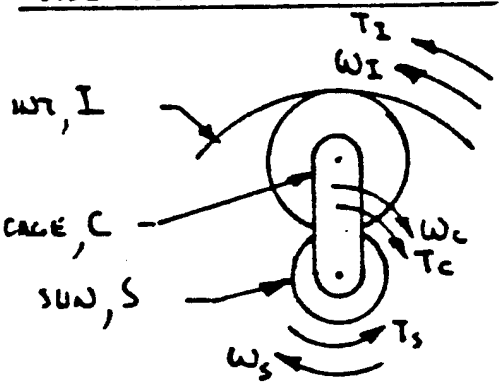
Signature	Date of Signature	Date of C

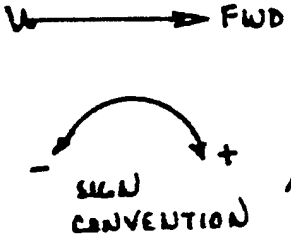
	Date of Signature	Date Understood

e) ARRANGEMENT #2 (INTERNAL = STEER MOTOR, SUN = PROP MOTOR, CAGE = OUTPUT)

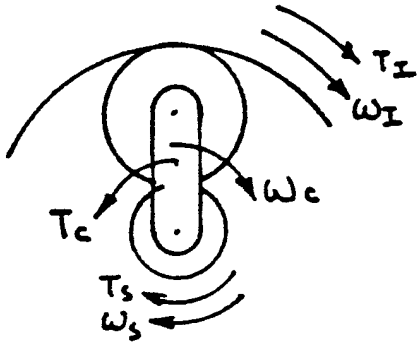
GEARING

SIDE DRIVING INNER TRACK





SIDE DRIVING OUTER TRACK



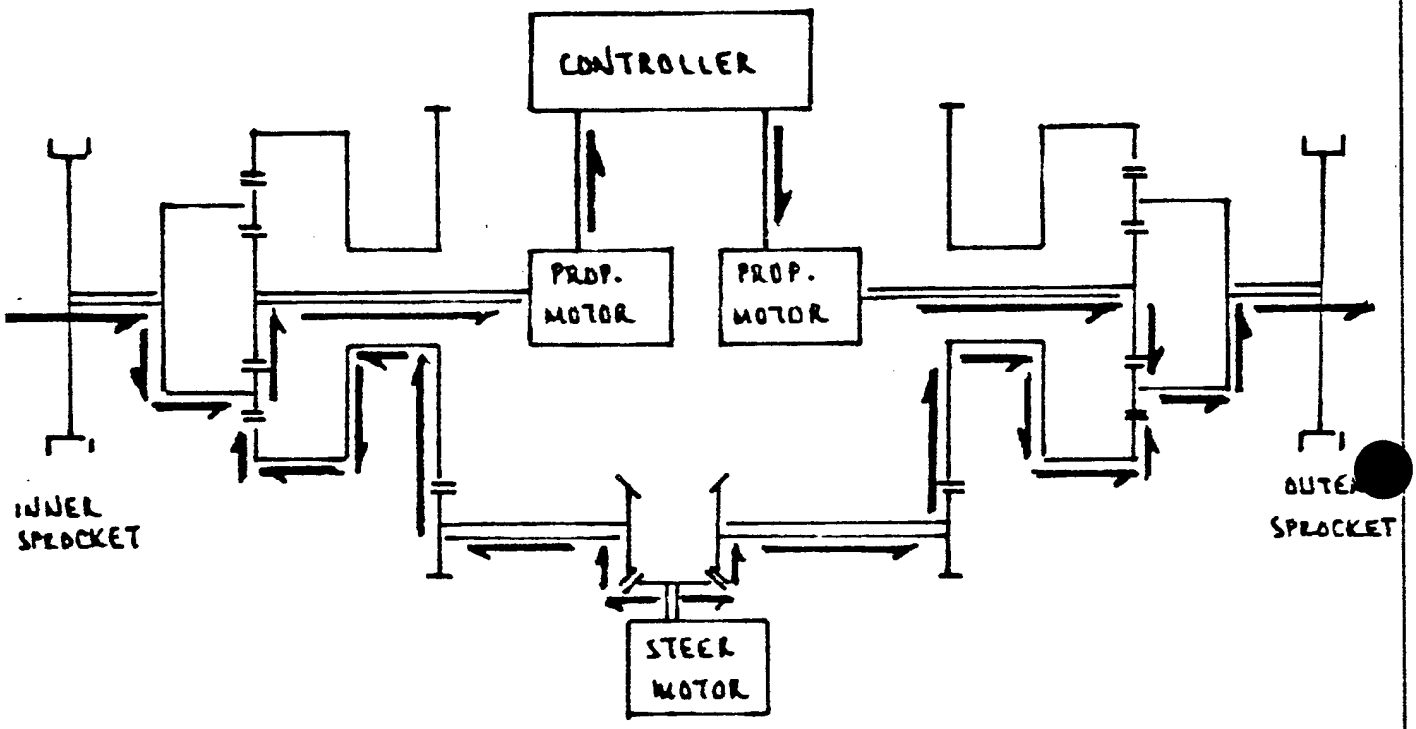
- SINCE THE INTERNAL GEARS ARE DRIVEN BY THE STEER MOTOR, THEY MUST HAVE OPPOSING SPEEDS AS SHOWN ABOVE.
- THE SIGNS OF THE TORQUE WILL BE THE SAME AS FOR ARRANGEMENT #1.
- THE SIGNS OF ω, T, HP WILL THEN BE :

	INNER TRACK			OUTER TRACK		
	I	S	C	I	S	C
	STEER MOTOR	PROP MOTOR	OUTPUT	STEER MOTOR	PROP MOTOR	OUTPUT
ω	−	+	+	+	+	+
T	−	−	+	+	+	−
▲ HP	+	−	+	+	+	−

▲ SEE SIGN CONVENTION ON PAGE 3 : − = OUT , + = IN

POWER FLOW SCHEMATIC

REGENERATIVE HP FLOWS INTO THE PROPULSION MOTOR, AND NOT THROUGH THE STEER CONTROL SHAFT.



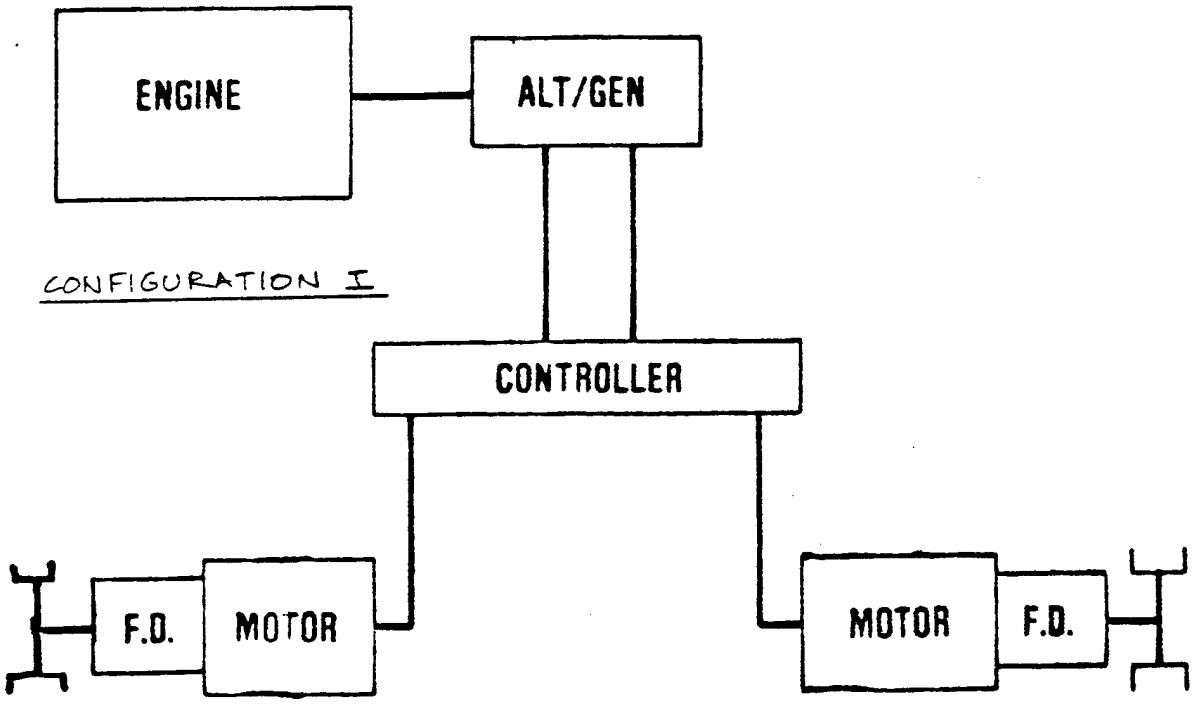
Signature	Date of Signature	Date of

	Date of Signature	Date Understood

4. RESULTS

- IN BOTH ARRANGEMENTS, THE POWER FLOW IS INTO THE PROPULSION MOTOR (FROM STEERING REGENERATION)

- BECAUSE REGENERATED POWER FLOW IS THRU INNER TRACK PROPULSION MOTOR TO CONTROLLER TO OUTER TRACK PROPULSION MOTOR, MOTORS AND CONTROLLER MUST BE SIZED TO TRANSFER REGENERATIVE LOADS. THIS IS THE SAME MANNER IN WHICH CONFIGURATION I OPERATES (SHOWN BELOW)

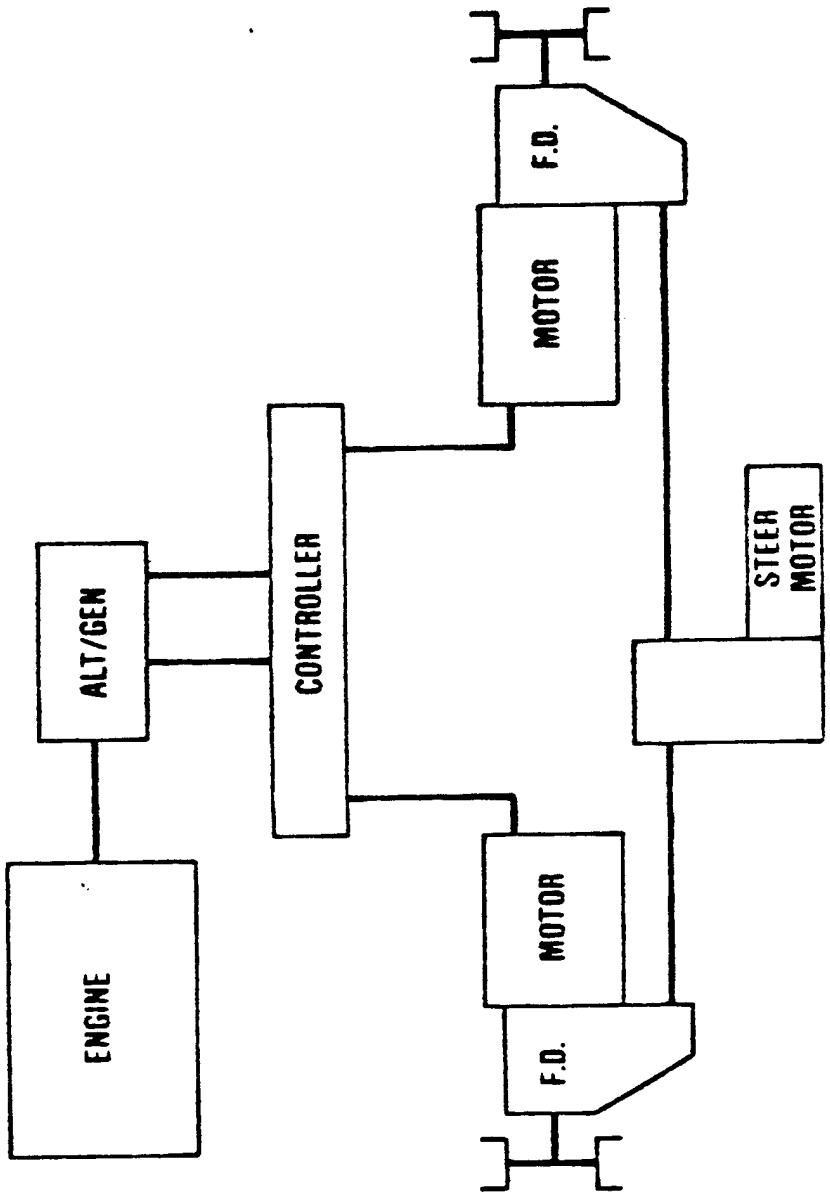


CONFIGURATION I

- IT IS THE FUNCTION OF THE PROPULSION SYSTEM TO TRANSFER POWER EFFICIENTLY, BUT CONFIGURATION II HAS THE BURDEN OF CARRYING A STEER MOTOR AND SHAFTING TO ACCOMPLISH THE SAME TRANSFER THAT CONFIGURATION I CARRIES OUT. A SUMMARY OF THIS FACT IS ON THE NEXT PAGE.

Title:

Configuration III



Detailed analysis shows regenerative HP flow is through the propulsion motors

∴ This arrangement has no advantage over Configuration I

Title: SIGN OF INT & SUN TORK

DISCUSSION

IN A COMBINING PLANETARY, WHEN WE APPLY THE SIGN CONVENTION FOR $\frac{IP}{\omega}$ (IE + = INPUT, − = OUTPUT) WE FIND THAT THE SUN & INT TORK MUST HAVE THE SAME SENSE (IE POSITIVE OR NEGATIVE SIGN)

WE WILL PROVE THE ABOVE PT. IN THE FOLLOWING ANALYSIS

CONVENTION

INPUT $\frac{IP}{\omega} = +$

OUTPUT $\frac{IP}{\omega} = -$

→ = APPLIED FORCE

⇢ = REACTION FORCE

) = $+\omega$

I a CAGE = OUTPUT

(PLANET TOOTH LOADS BOTH ARE "APPLY")

	INT	SUN
FORCES	REACTIVE	REACTIVE
DRIVER OR N	DRIVER	DRIVER
$\frac{IP}{\omega}$ SIGN	+	+
ω SIGN	+	+
TORK SIGN	+	+

▲ ROTATION IS OPPOSITE TO DIRECTION OF REACTIVE FORCE

Signature K. IRATA | Date of Signature 29 APR 81

Title: SIGN OF INT & SUN TORK

Ib CAGE = OUTPUT

(PLANET TOOTH LOADS APPLY & REACTIVE)

	INT	SUN
FORCES	APPLY	REACTIVE
DRIVER OR N	DRIVE N	DRIVE R
IN SIGN	−	+
ω SIGN	−	+
TORK SIGN	+	+

■ ROTATION IS IN SAME DIRECTION AS APPLY FORCE

Ib CAGE = OUTPUT

(APPLY & REACTIVE FORCES SWAPPED FROM Ia)

	INT	SUN
FORCES	REACTIVE	APPLY
DRIVE R OR N	DRIVE R	DRIVE N
IN SIGN	+	−
ω SIGN	+	−

Title: SIGN OF INT. & SUN TORK

II a CAGE = INPUT

(BOTH PLANET LOADS ARE REACTIVE)

	INT	SUN
FORCES	APPLY	APPLY
DRIVER OR DRIVEN	DRIVE N	DRIVE N
M_T SIGN	−	−
ω SIGN	+	+
TORK SIGN	−	−

II b CAGE = INPUT

(PLANET TOOTH LOADS ARE APPLY & REACTIVE)

	INT	SUN
FORCES	APPLY	REACTIVE
DRIVE R OR N	DRIVE N	DRIVE R
M_T SIGN	−	+
ω SIGN	+	−
TORK SIGN	−	−

Signature	Date of Signature	Its Signature	Date of Signature	Date Understood
[illegible]	29 Apr 85			

Title: SIGN OF INT & SUN TORK

II C CAGE = INPUT

(PLANET TOOTH LOADS SWAPPED FROM II b)

	INT	SUN
FORCES	REACTIVE	APPLY
DRIVE R or N	DRIVE R	DRIVE N
ω_P SIGN	+	−
ω_S SIGN	−	+
TORK SIGN	−	−

CONCLUSION

THERE ARE 6 POSSIBLE COMBINATIONS OF SUN : INT TORK AS SHOWN IN THE PRECEDING ANALYSIS. IN ALL 6 CASES, THE SIGN OF THE TORK ARE THE SAME (IE BOTH POSITIVE OR BOTH NEGATIVE)

APPENDIX D

CONFIGURATION IV ANALYSIS

Appendix D Configuration IV Analysis

The information in this appendix supplements the discussion in Section 5.2.6 in the main body of the report.

CVX 650 POWER

FLOW ANALYSIS

Title: XHM 650 T_{OUT} & HP

DISCUSSION

FROM ALLISON TABULATION OF SPDS & PARTIAL TABULATION OF TORQS, T_{OUT} & HP WILL BE CALCULATED

NOTE

(1) T_{OUT} NOT TABULATED IN ALLISON DATA
HENCE DETERMINED BY

1 & REV : $T_{OUT} = T_{S_2}\left(\frac{53}{56}\frac{132}{90}\right)$

2 : $T_K\left(\frac{132}{90}\right)$

(2) CALCNS FOR 3RD NOT PERFORMED SINCE THERE IS AN ERROR IN 3RD RANGE SPEEDS & PRESUMABLY IN TORK ALSO

(3) 100% GEAR EFF ASSUMED

(4) MAX "MOTOR" OUTPUT TORK OF 2437 IS FOR 100% PUMP-MOTOR TORK EFFICIENCY
IN FACT BOTH TORK & VOLUMETRIC EFF ARE ASSUMED TO BE 100% IN ALLISON TABLE SINCE PUMP HP = MOTOR HP
PUMP/MOTOR CIR = 35

APPENDIX E

ELECTRIC VEHICLE PERFORMANCE SIMULATION

Appendix E Electric Vehicle Performance Simulation

E.1 Major Program Capabilities

Electrically driven, tracked vehicle-performance is simulated by this software package. Parameters which may be investigated include detailed electrical system performance, vehicle track dynamics, system losses and efficiency, incremental and average gross vehicle dynamics, and fuel economy. There are four subprograms which have been created to specifically consider each of these areas in detail. A brief description of each is given below.

E.1.1 Constituent Subprograms

o Electric Drive Performance - Steady-state vehicle powertrain analysis with detailed emphasis on electric power drive parameters. Electric motor voltages, currents, generated power and alternator/generator output are calculated, along with energy usage, heat rejection, and fuel use impact.

o Vehicle Acceleration Performance - Analysis of dynamic vehicle performance which realistically simulates the gross vehicle mission over the terrain conditions. Acceleration, deceleration, braking, and constant velocity conditions are considered.

o Acceleration Dynamics Routine - Detailed analysis of full power acceleration during turning and nonturning maneuvers on user defined grades and surfaces. Incremental dynamic parameters are generated and tabulated.

o Reduction Dynamics Routine - Detailed analysis of speed/torque loading of all vehicle power train reduction elements. Final sprocket drives and prime mover interface reductions are included in the analysis.

Of four subprograms provided, the first two are perhaps the most useful for the consideration of the vehicle electric drive and the impact that it has on the overall vehicle mission. The latter two routines are best utilized for detailed investigation of those processes which help to make up the overall mission, but are not the parameters of major interest from a mission viewpoint. For this reason all further discussion will focus on the performance subprograms.

E.1.2 Performance Model Description

Each of the performance subprograms outlined above rely on an iterative energy balance technique to yield each steady-state operating point of the vehicle. The basic algorithm for this strategy is shown in Figure E.1.2-1. Test track parameters and

OUTPUT ALL CALCULATED DATA

performance requirements are defined and input by the user, along with vehicle, engine, and electric drive data which are resident within the program's data files. The vehicle dynamics are then calculated utilizing a Merritt's track model which considers the track dynamics based on empirical data. A centrifugal acceleration calculation is then performed to determine if any set acceleration limit is exceeded, such as personnel restrictions or vehicle track slip (surface coefficient or friction). If exceeded, the vehicle velocity is reduced and the process iterates until the acceleration falls within the selected bounds. The sprocket loads which have been calculated are used to determine what the electrical requirements are for each of the sprocket motors. This data is reflected back through the electrical system, ultimately to the prime mover, where the gross vehicle horsepower demand is calculated. At this point the energy balance is tested. If the fixed maximum output power of the prime mover is adequate for the present demand, the resultant system heat rejection and fuel consumption are calculated. If the system demands exceed the capabilities of the engine, the vehicle load is reduced by lowering the velocity until an energy balance is achieved. When this has been accomplished, either the calculated data is output to the user, as in the Electric Drive Performance subprogram, or it is further utilized in an acceleration or deceleration routine as in the Vehicle Acceleration Performance subprogram.

E.2 Program Options Available

The following six basic categories represent the various options which are available to the user from the program data files. Certain of the parameters must be defined by the user, such as the performance limitations which are addressed below.

E.2.1 Test Courses

There are four resident test courses provided within the software package. Each is broken down into segments of defined length, grade, and turn radius.

- o MERADCOM Test Course - This course consists of a well defined track which is located in the Aberdeen Proving Ground, Maryland. Sixteen segments make up the track, which has a total circumference of 2.5 miles.

- o Speed on Slope - A track consisting of thirteen segments of arbitrary length (1000 ft) was fabricated to aid in the derivation of the contractually required speed on slope curve. Grades from +60 percent to -60 percent are provided with intermediate grade points selected every 5 percent.

- o Tractive Effort vs. Speed - This test track is set up with grade values which yield a relatively uniform distribution of tractive effort values (TE) when plotted against speed.

o Churchville Test Course - This test course is the most rigorous and complex provided in the software package. Highly detailed topographical maps of the Churchville area (part of Aberdeen Proving Grounds) were used extensively in the definition of this track, which is comprised of 88 segments. Steep grades, sharp curves, and short segments serve to make this a very demanding and useful evaluator of vehicle performance. The course, which is 3.33 miles in length, is shown in topographic form in figure E.2.1-1, and in elevation in Figure E.2.1-2.

E.2.2 Course Surface

To provide greater flexibility in the number of options available to the user, the surface coefficient of friction (μ) is selected apart from the physical dimensions of each course. Those available are given below:

- o Concrete/Asphalt, μ = 0.80 (MERADCOM)
- o Compacted Soil, μ = 0.70 (Churchville)
- o Loose Sand, μ = 0.55
- o Rocky Terrain, μ = 0.45
- o User Defined

E.2.2 Vehicle/Engine

Both the 19.5 and 40.0 ton TACOM specified tracked vehicles are resident within the software package, as well as the specified engines (Cummins VTA-903 for the 19.5 ton, and the AD-1000 for the 40.0 ton). The option is also given to the user to define the parameters of their own tracked vehicle.

E.2.4 Engine Scheduling

Both constant and variable diesel engine scheduling is available to the user to aid the determination of which is more fuel efficient. Each technique utilizes fuel consumption curves for the VTA-903, and the AD-1000. With constant scheduling, fuel consumption is based on a relationship which is only dependent on demanded HP, whereas with variable scheduling, the demanded HP defines the engine speed which then yields the appropriate fuel consumption.

E.2.5 Electric Drive Type

The are eight electric drive types which are resident within the software package. The entire electric propulsion system is

defined for each.

- o Homopolar, Generator Driven (parallel/series systems)
- o Homopolar, Alternator Driven (parallel/series systems)
- o Brushless DC, Alternator Driven (low speed-high torque/high speed-low torque)
- o High Frequency Induction, Alternator Driven
- o Commutated DC, Alternator Driven

E.2.6 Performance Limitation

Several inputs not available for the internal data files are required of the user. These include:

- o Maximum (final) Forward Velocity
- o Maximum Forward Acceleration
- o Maximum Deceleration
- o Maximum Lateral Acceleration

E.3 Vehicle Mission Simulation and Analysis

E.3.1 Electric Drive Performance

The emphasis of this subprogram is the steady state analysis of electrically driven vehicles on a segment by segment basis as the vehicle maneuvers over a given course. It is best suited for analysis of steady state electric drive mission performance, particularly if the course of the mission is relatively uniform, and the segments of each course segment are lengthy in comparison to the time it takes the vehicle to traverse them. Detailed sprocket data (see Figure E.4-2) for each track is available to the user, as well as the equivalent sprocket motor dynamics. Motor and system electrical data is also generated, including voltages, currents, and power, including the net power which must be supplied (or absorbed) to both sprocket motors from the bus. These parameters aid in the evaluation of the system operation during turns and regenerative conditions, and allow the magnitudes and directions of system energy flow to be easily monitored. Net drive efficiency along with generated and lost energy are also provided to determine if overall system performance is within acceptable limits. These energies are reflected in terms of required prime mover power and the resultant fuel consumption. For further mission analysis, fuel economy is calculated, and a range estimate based on a specified vehicle fuel tank volume is made.

E.3.2 Vehicle Acceleration Performance

For any vehicle mission, this subprogram provides the user with the most realistic assessment of vehicle performance over any course conditions. All vehicle transitory states (i.e., acceleration, deceleration, braking) between constant velocity conditions are considered in order to yield smooth vehicle motion throughout the course. The subprogram is specified for overall mission analysis rather than an electric drive component evaluation. This is evident in the printed output page (see Figure E.4-3) which provides detailed acceleration/deceleration information, but no internal electric drive data. The complete electric drive models are utilized for this analysis but the transitory nature of the vehicle drive during the test periods makes it difficult to extract any meaningful output of the electrical parameters.

As with the Electric Drive Performance subprogram, power supplied by the prime mover is determined along with the system energy which is generated and lost. Fuel consumption data is presented as well as the full fuel tank range estimate. Cumulative mission information is available for each segment of the course, and can provide a useful means of evaluating incremental mission performance.

E.4 Program Outputs

Examples of the information which each of the subprograms outputs to the user are given in Figures E.4-2 to E.4-5. Figure E.4-1 is the main program header sheet that is included with each run to specify which subprogram is in use and which echoes all the data that has been input by the user.

ELECTRIC VEHICLE MISSION SIMULATION

FMC / NORTHERN ORDNANCE DIVISION
MINNEAPOLIS, MINNESOTA USA

REVISION DATE: 12/10/84
RUN DATE: 5/21/85

ELECTRICALLY DRIVEN, TRACKED VEHICLE PERFORMANCE IS SIMULATED BY THIS PROGRAM. DETAILED ASPECTS OF VEHICLE PERFORMANCE CAN BE INVESTIGATED USING THE FOUR RESIDENT SUB-PROGRAMS LISTED BELOW. THE SUB-PROGRAM IN USE IS IDENTIFIED WITH AN ASTERISK.

* 1.)	ELECTRIC DRIVE PERFORMANCE -	STEADY STATE VEHICLE PERFORMANCE ANALYSIS WITH DETAILED EMPHASIS ON ELECTRIC POWER DRIVE PARAMETERS. ENERGY USAGE, HEAT REJECTION, AND FUEL IMPACT ARE ALSO CALCULATED.
2.)	VEHICLE ACCELERATION PERFORMANCE -	DYNAMIC VEHICLE PERFORMANCE ANALYSIS WHICH REALISTICALLY SIMULATES GROSS VEHICLE MISSION OVER ALL TERRAIN CONDITIONS. ACCELERATION, DECELERATION, BRAKING AND CONSTANT VELOCITY CONDITIONS ARE CONSIDERED.
3.)	ACCELERATION DYNAMICS ROUTINE -	DETAILED ANALYSIS OF FULL POWER VEHICLE ACCELERATION DURING TURNING AND NON-TURNING MANEUVERS ON USER SELECTED GRADES AND SURFACES. INCREMENTAL DYNAMIC PARAMETERS ARE GENERATED AND TABULATED.
4.)	REDUCTION DYNAMICS ROUTINE -	DETAILED ANALYSIS OF SPEED/TORQUE LOADING OF ALL VEHICLE POWER TRAIN REDUCTION ELEMENTS. FINAL SPROCKET DRIVES AND DIESEL ENGINE INTERFACE ARE INCLUDED IN ANALYSIS.

CONTRACT VEHICLE AND PROPULSION SYSTEM SPECIFICATIONS

ATTACHMENT 1

SPECIFICATIONS

1. General Vehicle Specifications (Fig. 2):

Frontal Area	6.34 sq m (68.25 ft^2)
Gross Vehicle Weight	36.3 ton (40 ton)
Vehicle Top Speed (Governed)	73 Km/hr (45 mph)
Track Length (forward to aft roadwheel centerline)	4650 mm (183.07 in.)
Distance between track longitudinal centerline)	2790 mm (109.84 in)
Track Width	580 mm (22.83 in.)

2. Propulsion System Specifications:

a. Transmission: (Electric Drive System)

The drive system shall provide automatic speed ration control and inhibitors to prevent engine overspeed. Maximum output torque required shall be sufficient to generate a tractive effort of 427,000 Newtons, Reverse - 427,000 Newtons. There shall be tactile feedback to the driver when the transmission is in forward or reverse operational mode. The power train shall provide for safe, predictable performance for extended periods at speeds below 5 Km/hr.

b. Steer System:

A regenerative speed control system is required. Differential torque between sides shall be equal to maximum steer torque. Pivot steer capability on hard surface shall be 7 revolutions/min. The steering controls shall remain operative in the event of engine failure or vehicle towing. The steer system shall be capable of accepting full engine power.

c. Coding Capability:

Capable of continuous tractive effort operation of at least 250,000 N.

d. Braking:

The vehicle shall be capable of a deceleration rate from maximum speed on level hard surface road at least 7 m/sec^2 (peak) and 5 m/sec^2 (avg.). The vehicle shall be capable of an included hold with engine off on at least a 60% slope. The vehicle shall be capable of at least 25 stops from 60 Km/hr @ 5 m/sec^2 @ 3 minute intervals. The braking functions shall be accomplished by two separate mechanisms to allow redundance for emergency purposes.

e. Electric/Hydraulic Power Capability:

Continuous operation of all vehicle electrical and hydraulic systems shall be at least 7 Kw, to include silent watch - the silent watch is non-mobile, with noise, light, and smoke discipline. The above power requirement covers turret hydraulic, radio and other electrical needs, compartment ventilation and NBC countermeasure equipment. Electrical and hydraulic power sources must be capable of operating independently or in parallel in a stable self regulating manner. Average auxiliary power usage is 3.5 Kw.

f. Speed on Grade:

The propulsion system shall be capable of sustaining forward vehicles speeds on hard surface roads and grades as defined in Figure 1.

g. Acceleration:

The vehicle shall be capable of acceleration on dry level surface from idle, from application of the throttle, in the forward direction from zero to 32.2 Km/jr (20 mph) in seven seconds; and in reverse direction from zero to 16 Km/hr (10 mph), in five seconds. Assume no "throttle" linkage delay.

h. Engine: See figures 4 and 5.

i. Shock:

The electric drive system must be able to withstand a 15-g shock load in any direction.

ATTACHMENT 2

SPECIFICATIONS

1. General Vehicle Specifications (Fig. 3):

Frontal Area	5.3 sq m (57 ft^2)
Gross Vehicle Weight	17.6 ton (19.5 ton)
Vehicle Top Speed (Governed)	73 Km/hr (45 mph)
Track Length (forward to aft roadwheel centerline)	3810 mm (150.0 in)
Distance between track longitudinal centerline)	2350 mm (92.52 in)
Track Width	445 mm (17.52 in)

2. Propulsion System Specifications:

a. Transmission: (Electric Drive System)

The drive system shall provide automatic speed ration control and inhibitors to prevent engine overspeed. Maximum output torque required shall be sufficient to generate a tractive effort of 208,000 Newtons, Reverse - 208,000 Newtons. There shall be tactile feedback to the driver when the transmission is in forward or reverse operational mode. The power train shall provide for safe, predictable performance for extended periods at speeds below 5 Km/hr.

b. Steer System:

A regenerative speed control system is required. Differential torque between sides shall be equal to maximum steer torque. Pivot steer capability on hard surface shall be 7 revolutions/min. The steering controls shall remain operative in the event of engine failure or vehicle towing. The steer system shall be capable of accepting full engine power.

c. Cooling Capability:

Capable of continuous tractive effort operation of at least 121,500 N.

d. Braking:

The vehicle shall be capable of a deceleration rate from maximum speed on level hard surface road at least 7 m/sec^2 (peak) and 5 m/sec^2 (avg.). The vehicle shall be capable of an included hold with engine off on at least a 60% slope. The vehicle shall be capable of at least 25 stops from 60 Km/hr @ 5 m/sec^2 @ 3 minute intervals. The braking functions shall be accomplished by two separate mechanisms to allow redundance for emergency purposes.

e. Electric/Hydraulic Power Capability:

Continuous operation of all vehicle electrical and hydraulic systems shall be at least 7 Kw, to include silent watch - the silent watch is non-mobile, with noise, light, and smoke discipline. The above power requirement covers turret hydraulic, radio and other electrical needs, compartment ventilation and NBC countermeasure equipment. Electrical and hydraulic power sources must be capable of operating independently or in parallel in a stable self regulating manner. Average auxiliary power usage is 2.5 Kw.

f. Speed on Grade:

The propulsion system shall be capable of sustaining forward vehicles speeds on hard surface roads and grades as defined in Figure 1.

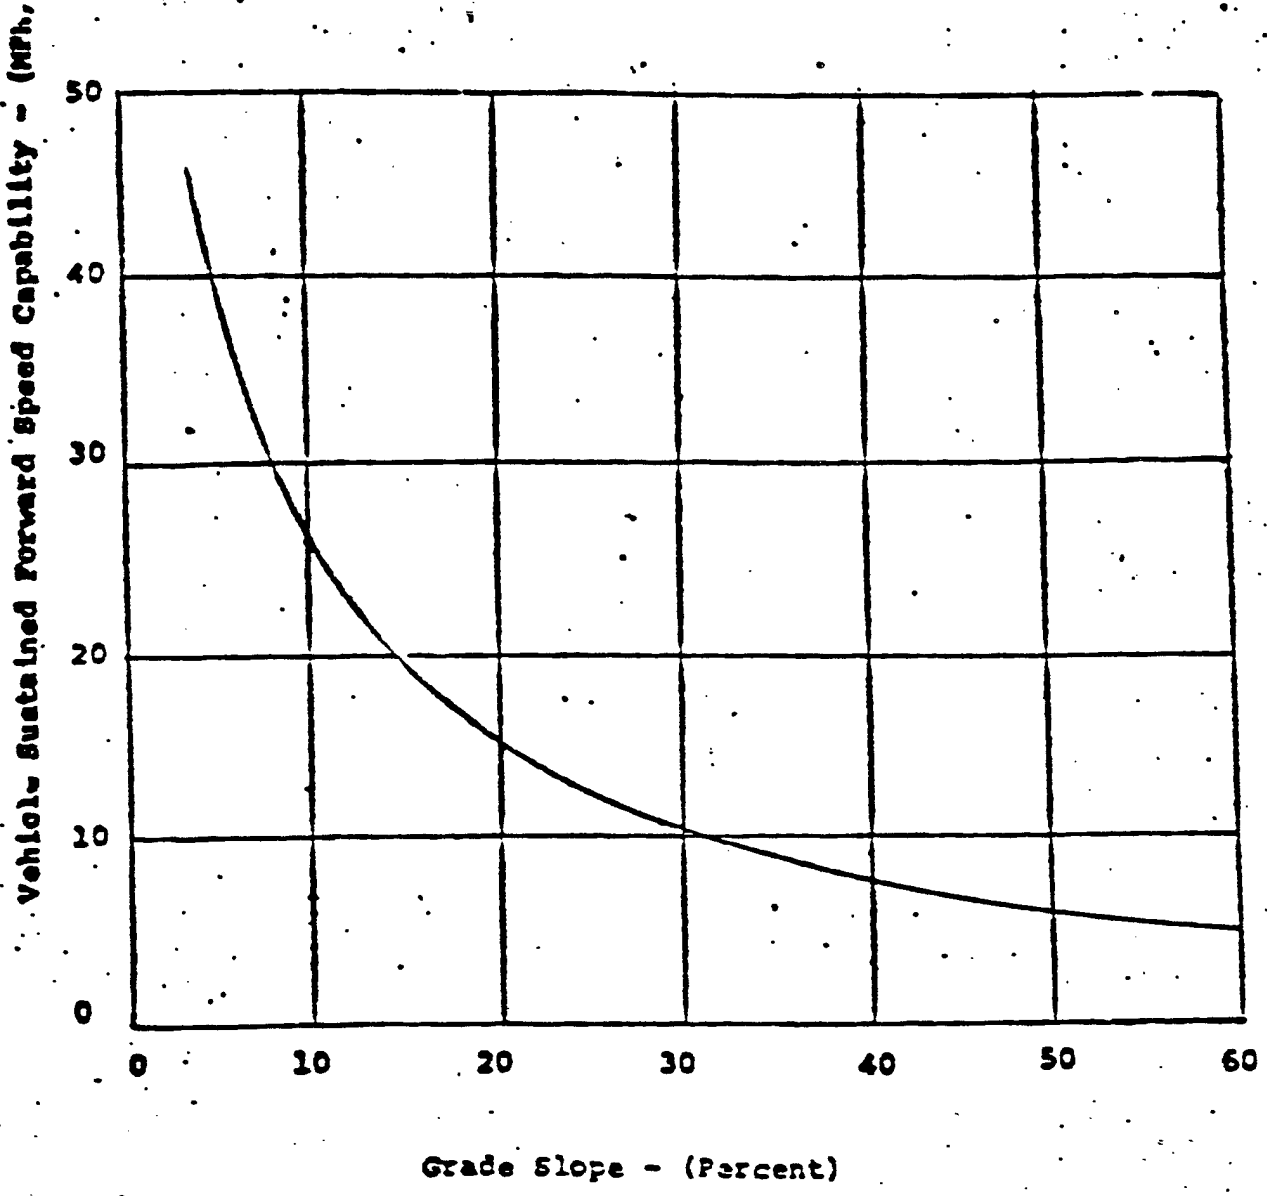
g. Acceleration:

The vehicle shall be capable of acceleration on dry level surface from idle, from application of the throttle, in the forward direction from zero to 32.2 Km/jr (20 mph) in seven seconds; and in reverse direction from zero to 16 Km/hr (10 mph), in five seconds. Assume no "throttle" linkage delay.

h. Engine: See figures 4 and 5.

i. Shock:

The electric drive system must be able to withstand a 15 g shock load in any direction.



NOTE: Performance shall be measured over hard-surface roads.

HOMOPOLAR MACHINE DESCRIPTION

APPENDIX G Homopolar Machine Description

One of the vehicle drive system concepts selected utilizes homopolar (single pole) machines as the propulsive component. These direct current (DC) machines are characterized by the low voltage ($\lesssim$ 50V) and high current nature of their output and the simplicity which is inherent in their design.

G.1 Homopolar Machine Operation

G.1.1 Voltage Generation

Operation of the homopolar machine is governed by Faraday's Law, which relates the mechanical machine parameters, rotational velocity, and magnetic flux to the voltage produced across the rotor (armature). Specifically, $V \propto Bwr\ell$ where;

V = the voltage generated across the armature

B = the density of the magnetic flux passing through the rotor

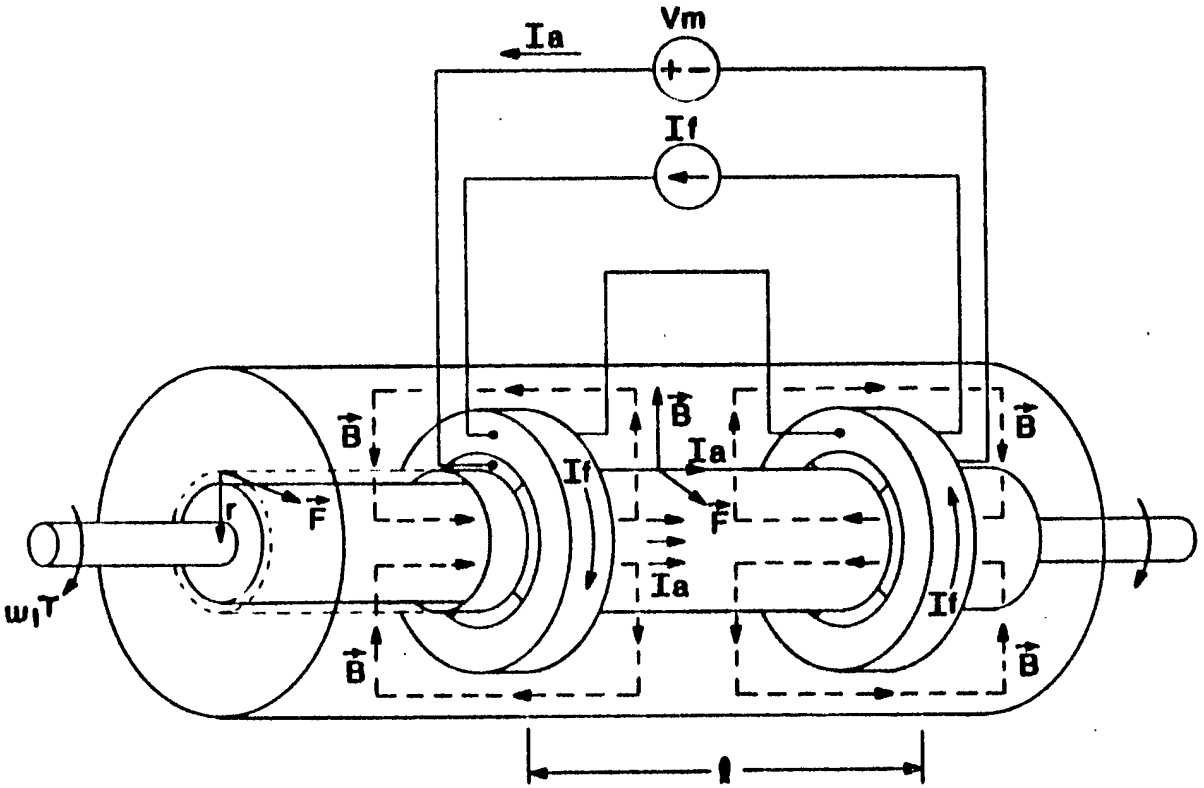
w = the rotational velocity of the rotor

r = the radius of the rotor drum

ℓ = the active machine length (defined as the length of the rotor across which the magnetic flux passes)

The manner in which this relation is satisfied by the machine is shown in Figure G.1.1-1. A solid rotor drum, made of iron or other low magnetic reluctance material, is captured within a thin conducting sleeve which is electrically insulated from the rotor. Electrical connections are made around the periphery at each end of the sleeve by a series of sliding brush contacts. Field coils, which are wound in opposite directions from one another in a circumferential manner, are placed around the rotor near each end. The entire structure is encased within a housing of magnetic material to provide a low reluctance return path for the magnetic flux. During operation as a generator (the homopolar machine acts equally well in a motoring mode) the field coils are excited with a DC current If, giving rise to a toroidally oriented magnetic flux about each of the coils. The net flux density which passes across the active length of the rotor (ℓ) is the combined field from each of the field coils. As the rotor is turned at a rotational speed w, the lines of magnetic flux B are constantly cut by the active length ℓ, generating a differential voltage across the rotor drum which satisfies Faraday's Law. This voltage is available at the two brush rings, and if connected to a load, will result in the flow of armature current I_a.

BASIC HOMOPOLAR MACHINE OPERATION



Defining Equations: $d\vec{T} = (Ia\,d\vec{l} \times \vec{B}) \times \vec{r}$, $[|\vec{T}| = Ia\,\ell\,|\vec{B}|\,|\vec{r}|]$

$$Vm = Va + IaRa \quad \text{where} \quad Va = N\frac{d\vec{\Phi}}{dt} = (1)|\vec{B}|\frac{dA}{dt} = |\vec{B}|\ell\frac{de}{dt} = |\vec{B}|\ell\omega$$

$$[Vm = |\vec{B}|\ell\omega + IaRa]$$

G.1.2 Torque Generation

The generation of torque by the homopolar machine is governed by the vector relation $\vec{F} = Ia\,(\vec{l} \times \vec{B}) \times \vec{r}$ and is best understood through consideration of the machine in a motoring mode. With the field coils excited and a potential Vm applied across the armature, an armature current Ia flows proportional to whatever resistance is encountered in the armature circuit. The interaction of the two orthogonal vectors in the directions of the magnetic flux and the armature current give rise to a generated force tangential to the rotor drum. The vector cross product of this force with the radius vector of the machine results in a generated torque about the axis of the rotor. This torque is then transmitted along the shaft.

G.2 Homopolar Machine Characteristics

G.2.1 Machine Losses

Homopolar electrical losses are a function of three components; field coil resistance, armature sleeve resistance, and brush contact potential drop and resistance. Of these, the brush losses are the most significant contributor, due to the resistance vs wear tradeoff which must be analyszed when the brush materai is selected. For example, a greater brush force will accelerate brush wear, but will result in a lower resistance and less heating. Lower heat dissipation then helps to lengthen brush life. Active brush cooling helps to reduce some of these factors significantly. Mechanical losses are those normally associated with rotary machinery; i.e., friction and windage. These losses are most prevalent in the machine, and account for the majority of the total losses, particularly if there is little electrical load.

G.2.2 Speed/Torque Characteristics

Electrical machines are characterized by the speed vs torque profile which defines the operatng limits at any particular load. A representative curve for a homopolar machne is given in Figure G.2.2-1. The primary machine limitation is thermal rather than magnetic saturation or reaction torque demagnetization (as with permanent magnet DC motors). As long as adequate heat removal is provided, the homopolar machine can deliver rated torque over the full speed range of the machine. Higher, noncontinuous torques at stall or very low speeds are also attainable and can be maintained with sufficient cooling. Stall torque levels are ultimately limited by brush current density, which coupled with the rotor tip speed, for an envelope whic defines the maximum transient load.

G.2.3 Homopolar Gain/Control

A primary advantage of homopolar machines is the ability to control their operation through excitation of the field windings

at a much reduced power level. This is in contrast to all AC drive systems which require that a series controller capable of handling the entire motor power be used to generate the necessary AC waveforms. Homopolar machine gain is defined as the ratio of the output power (mechanical for the motoring mode, electrical for the generating mode) to the full excitation power of the field coils. Present homopolar designs yield gains on the order of 25. The method of control is best demonstrated by Figure G.2.3-1, which presents a family of linear speed vs voltage curves. Due to the simplicity of construction and single pole nature of the machine, generated armature voltage is a linear function of rotational velocity. The magnitude of the voltage is controlled by the level of magnetic flux in the machine. Since the flux level is directly proportional to the field current provided, a control parameter for machine speed is realized. In a similar manner, as shown in Figure G.2.3-2, the armature torque generated is a linear function of the armature current and the flux level. Hence torque control is also realized through this same control parameter. In a system which incorporates a homopolar motor and a generator, both speed and torque control are available to the user.

G.2.4 Power Density

Power densities of homopolar machines are moderate in comparison with those of competing technologies. Although significantly better than those of conventinal DC machines or industrial AC induction motors, homopolar power densities are not as great as those of machines excited by high frequency AC (i.e., high frequency synchronous or hybrid, brushless machines). This is due in part to the low induction level of materials available and thus the amount of magnetic material required to carry the necessary flux levels. It should be realized, however, that if the weight and volume requirements of the series controller required by each of the AC systems is incorporated into an overall system weight for each of the alternate technology macines, a more equitable comparison is achieved. In such a comparison the power density of the homopolar system is competitive.

G.2.5 Thermal Requirements

The homopolar machnes recommended for use as vehicle propulsive elements require liquid cooling for proper operation under normal vehicle loads. This is also true for other high performance technologies (i.e., high frequency AC driven machines). Internal cooling of the homopolar machine rotor drum and brush assemblies are flood cooled, and coolant is circulated through each of the field coils. There is no requirement regarding the ion content of the coolant due to the low potentials which exist within the machine. Precautions, however, should be taken to maintain coolant cleanliness consistent with that required by machines of similar precision.

G.2.6. Rotor Inertia

Rotor inertia of drum configured homopolar machines are competitive will all alternate technology machines and in many cases, such as with large diameter brushless motors (LSHT), are significantly better. Rotor magnetic material mass is the primary influence on this parameter due to the requirement of a complete flux circuit path. Several innovative inertia reduction techniques have been proposed which could ultimately reduce homopolar inertias to less that 25 percent of present designs, resulting in extremely responsive high power machines with servo-drive applications.

APPENDIX H

AC MACHINES OPERATION

H.1 General

In this section, induction, synchronous, and permanent magnet machines are briefly described in terms of their operation.

H.2 Induction Motors. Induction motors are probably the most universal of all motors in present use. They are characterized by extreme simplicity, very rugged construction, high reliability, and low manufacturing cost. AC induction motors can be designed to operate over wide frequency extremes and are very tolerant to waveshape (although reasonable sine waves are preferable), and applied voltage variations. They can be easily designed for single, two, or three or more phased operations. While single-phased motors are not easily reversible, three-phased designs can be reversed electrically.

Operation of induction motors is best described by transformer theory. For simple example purposes, the stator winding can be considered as the primary winding and the rotor the secondary winding. However, the rotor winding is essentially a number of parallel, shorted turns. Thus, voltage so induced across the airgap causes a voltage and appropriate current to circulate in the rotor windings. This rotor current produces a reactive force which opposes the stator current, producing rotation of the armature which is attached to the output shaft. The motor/transformer analogy, however, is no longer valid when the airgap is considered. In a well-designed multiphase power transformer, the airgap is made as small as possible to minimize the loss in power conversion from the primary to secondary winding. In the induction motor, the airgap must provide a correct balance of induced flux in the rotor and airgap loss. Due to the series relationship of the motor windings and the airgap, and the low resistance of the rotor windings, large currents flow in the rotor conductors when small voltages are present at the rotor windings. This action directly depends on the voltage and current relationships resulting from application of the turns ratio of the stator and rotor windings.

The motor "series" airgap thus balances the excess voltage flux wave not required by the rotor to maintain the rotating speed. In the transformer analogy, this would be equivalent to a high leakage reactance design with a mechanical separation between primary and secondary windings. In this specific case, the leakage reactance balances the excess flux when the secondary winding is shortcircuited.

So far, the discussion has established the theory of rotation for the armature. For the armature to actually rotate, the airgap flux wave must also rotate, either continuously, as in a three-phase AC system, or instantaneously, as in a single-phase AC system. For single-phase systems, a capacitor or separate start-winding is required to shift the phase of the airgap flux wave to start rotation. However, for electric vehicle use, we will consider only the three-phase power system since the three-phase AC system has a naturally occurring flux field rotation.

The transformer analogy of induction motors can also be extended to the relative size of the motor. The well known transformer equation relating flux density, applied voltage, core area, and frequency (a specific application of Faraday's law) applies directly to AC induction motors. Thus, for low frequency AC systems, the area and volume of stator and rotor iron required to support the applied voltage will be greater than for higher frequencies. Coupled with the naturally rotating flux wave of three-phase systems, this sets the physical dimensions of the motor. It also allows for a convenient control of motor speed by varying the applied frequency, since changing the frequency results in a change in the rotating flux field in the airgap. Generally, industrial induction motors can be operated over a minimum of 2/1 speed range with some operation of up to 4/1.

Electric vehicle application experience using AC induction motors has been favorable. Extensive design and testing of induction motor powered vehicles took place in the early 1970's. The test results were generally satisfactory--the major problem being the reliability of the variable frequency inverter. The development effort did, however, establish desirable characteristics for the induction motor (mainly reduced size and weight, and improved efficiency) for electric vehicle use.

H.3 Synchronous Motors. In the discussion dealing with induction motors, it was established that the rotor reactive force is developed by induced voltage and the resultant current is transformed from the stator winding. As the reactive force creates armature rotation, the actual armature positional relationship with respect to the induced rotor flux will be slightly retarded. As the motor approaches full speed, the positional relationship becomes relatively constant, and thus rotates at a speed equal to 3 to 10 percent of the applied frequency base speed. This difference in rotor speed as a ratio of base speed is defined as the slip speed.

A special case can be made for AC induction motor designs in which the slip ratio is held at unity. Under this circumstance the rotor speed and the field flux rotational speed are equal. Motors of this type thus have a synchronous speed relationship, and bear this name. Synchronous motors are characterized by having wound rotors which can be separately excited from an external voltage source, rather than excited through induction from the stator winding. This capability allows for establishing a high reactive force in the armature, even at zero rotor speed. It holds that the stator induced field flux and the rotor reactive force developed from separate power can be individually controlled. Since the rotor reactive force determines the motor torque and the stator frequncy controls the motor speed, the synchronous motor has the inherent characteristics desirable for electric vehicle applications. An additional control characteristic is available in synchronous motors because of slip frequency. Since by definition, synchronous operation requires that the slip frequency be unity, a change in slip frequency requires a corresponding in rotor speed to maintain the motor magnetic circuit in balance. In synchronous motors, the slip ratio can be controlled by a change in the rotor

excitation. Thus for electric vehicle applications, either the stator frequency or rotor excitation may be changed to command acceleration or deceleration, as required.

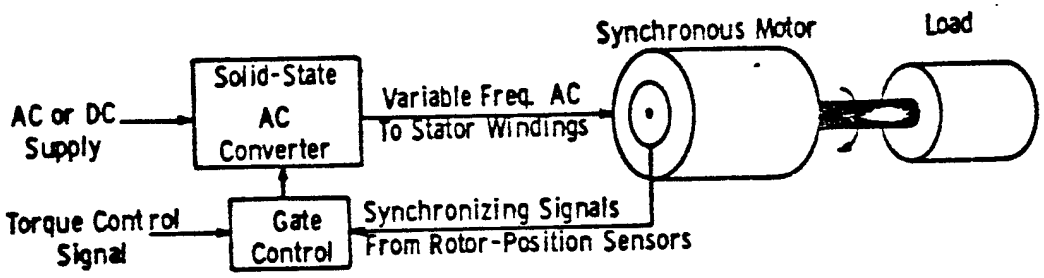
Recent developments in synchronous motors and generators have eliminated the requirement for direct excitation connections to the rotor windings. Figure H.3-1 illustrates the system for controlling the rotor excitation by additional components attached to the common output shaft. The key feature of this system is the integral AC exciter/alternator and rotating rectifiers. This system can produce the required rotor excitation very efficiently due to the transformation action of the alternator. System controlability is excellent due to the high gain available in the control loop. Due to the transformation characteristics of the AC exciter, small, low-power error signals can command the motor/generator system over the full-rated power range. Response times are very short and thus the system is very reactive to operator inputs. This command/control characteristic is desirable in electric vehicle drive systems to maintain both responsiveness and stability.

H.4 Permanent Magnet Brushless DC Motors. During the mid-1950's, development of high energy magnet materials allowed designers to employ these permanent magnets in motor structures as the source of rotor excitation. As permanent magnet materials have improved, designers have applied them to larger motors which at present range up to 50-100 Horsepower. Early development of the permanent magnet motor was characterized by simply substituting the magnet for a wound-field structure in shunt-wound DC motors. The motor thus performed in a similar fashion to the conventional, DC mechanically-commutated motor, except that motor speed increased linearly with applied voltage. This characteristic is due to the fixed, constant-level of field flux generated by the permanent magnets.

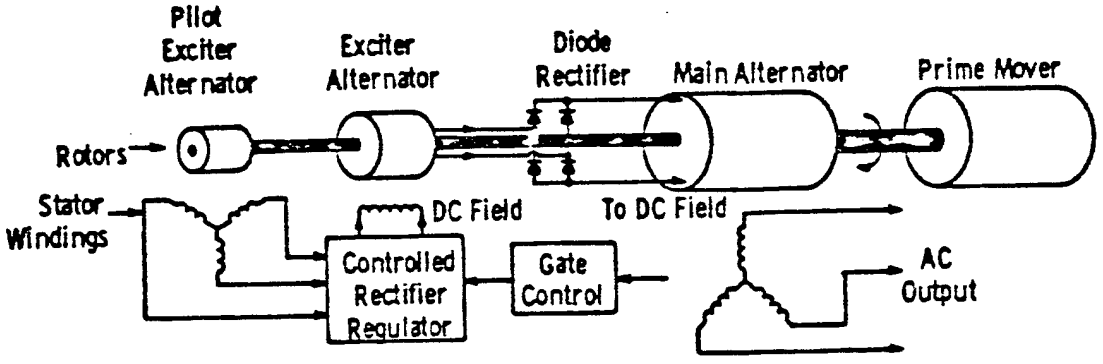
While the speed versus applied voltage linearity was recognized as a desirable characteristic, the speed versus torque curve reacts in an opposite manner. Thus, while speed increases with voltage, torque decreases with speed in a reasonably linear fashion. These features of the permanent magnet motor, while usable in many applications--including small electric vehicle drives, would not be sucessful in large electric vehicle drives where extreme performance is the requirement.

Within the past ten years, development efforts in permanent magnet motors have produced a true hybrid motor. These hybrid motors have many of the desirable characteristics of DC motors (such as speed versus voltage linearity) while being controlled and commutated from an AC source. This family is generally labeled "Brushless" DC motors.

Brushless DC motors are characterized by their construction which is similar to a conventional multiphase AC motor, except the usual peripheral field permanent magnets are replaced by a multiphase (usually three) winding powered by an electronic inverter. The inverter is operated at selected frequencies which are dependent on motor design and provide the electronic commutation function. The permanent magnets are attached to the rotor in a manner which



(a) High Frequency AC Synchronous Motor Drive



(b) High Frequency AC Synchronous Alternator

Figure H.3-1. Diagrammatic Representation of Brushless Excitation System

provides for field flux in the stator/rotor airgap. This design allows for considerable flexibility in the rotor design and the number of poles available for reacting with the rotor. These design variables result in two basic brushless motor designs: one having small rotor diameters, few poles, and a magnet length dependent upon the horsepower requirement; and one having large rotor diameters many poles and, relatively short magnet length. Generally these two motor types are classified as High Speed/Low Torque (HSLT), and Low Speed/High Torque (LSHT) designs.

Excellent thermal characteristics is one of the major features of the brushless motor design. With the heat-generating windings situated on the stator, low thermal resistance in the stator iron allows for relatively unimpeded heat flow to the outside motor shell. Appropriate cooling can be employed to removed this heat and maintain the motor at rated temperature. Very little heat is generated by the permanent magnet rotor structure and, consequently, the rotor temperature rise is minimized.

General reliability of brushless motors is very favorable. Care must be used in selecting the motor type, however, so that vibration and shock do not cause damage to the magnet structures. Although minor cracking of the magnets will not cause a major motor failure, cracks can cause degradation in motor performance. A more significant failure can result if the magnets fragment and produce chips which can lodge in the airgap.

Brushless DC motors offer desirable features to electric vehicle drives. The control characteristics, when considered with the capabilities of electronic commutation controllers, offer the potential for independent speed and torque control. Motor efficiency is high and the construction provides excellent thermal dissipation. Further, as defined by the vehicle specifications, the brushless motor may be designed for high- or low-speed operation with the appropriate resultant torques.
