Project Objectives

Surreptitious communication through steganography has application in many settings. There are many different techniques for hiding steganographic content and in theory, any file type can serve as a carrier. Most studies in steganalysis have focused on single file types and a few steganographic methods on those file types, representing a limited sample of the population of transmitted data. In our Phase I effort, we proposed to develop a general-purpose steganalysis system that would handle many file types and many steganographic methods, while being easy to configure and use. Such a system could be deployed widely enough to adequately sample a statistically significant portion of transmitted data. A distinguishing feature of our proposed approach was the use of machine learning techniques to create a file type classifier that can be used to select among available steganalysis modules. The resulting system was to be modeled on modern antivirus software, capable of background monitoring of files, email, and web pages visited in a browser.

Our plan was to create a flexible, efficient framework, called *StegKit*, into which steganalysis components could be placed or "plugged in" to carry out automated and manual analysis within common operating environments. Specific steganalysis algorithms and techniques, while important for demonstrating feasibility and the concept of operations, were a lesser concern in Phase I, but were anticipated to be a the primary focus of Phase II. The framework to be created in Phase I was to provide a stable and well-defined platform for rapid testing, evaluation, and evolution of steganalysis components in Phase II. In Phase I, we proposed to develop for deployment under the Microsoft Windows operating system (either Windows 2000 or Windows XP).

Existing steganalysis tools, such as *stegdetect* [24], tend to be structured as utility programs, invoked from the command line and applied to suspect files one at a time.

While effective for checks of a small number of suspect files, they are not packaged in a way that supplies their services in a continuous background fashion covering, for example, all material accessed through a web browser. The existing tools also tend to focus on a single cover file type (e.g., image files in JPEG encoding), thus requiring the user to select the appropriate utility for maximum efficacy.

Some work reported in the literature [22] has adapted command line utilities to work in a "batch" mode against suspect files collected by a separate web spider process. This technique has been used to examine large numbers of image files from EBay and Usenet newsgroups as a means of assessing the prevalence of steganographically concealed material on the Internet. The batch approach, while effective for the purpose of the research effort, is not well suited to the dynamic environment of everyday PC use. Furthermore, it also restricted the analysis to a single file type, also inappropriate for use in a dynamic setting.

As noted in the original STTR topic description, a more appropriate packaging model would be computer virus checking. Virus checkers typically can be used under manual control, scanning anything from the current contents of memory, through a single file, all the way to all drives on a computer. They can also usually be configured to run automatically, unobtrusively examining every file as it is created, or every new email as it is received from the mail server. (Some checking software runs on the mail server itself, checking before messages are passed to the mail client.) The specific file type is irrelevant to the virus checking process, though some file types known to compress or otherwise package content (such as zip files or Microsoft cabinet files) may be expanded before being checked. Users frequently have some control over the action taken when a virus is detected, ranging from simple reporting through "quarantining" where the infected file is isolated in a protected area of the directory structure, through to deletion. In some cases, the virus analysis may produce sufficient information to permit disinfection, or removal of the viral component and salvaging of the original, uninfected file.

With this in mind, our objective in Phase I was to demonstrate the feasibility of creating a steganalysis tool that packages steganography detection in a manner similar to that of a virus checker. The functionality of this tool was to be partitioned between a framework and plug-ins, with the plug-ins providing specific steganalytic techniques and the framework providing necessary support services including file handling and user interface. The complete tool, consisting of the framework plus a plug-in based on existing steganalysis components, was to:

- automatically identify all newly created files on the subject computer, including file type,
- identify all newly received email messages on the subject computer, including file type for any attachments,
- perform appropriate steganalysis on the new material, based on the file type,
- report, in a form selected by the user, whenever steganographic content is detected in analyzed material,

- offer a means for the user to manually invoke steganalysis on one or more selected files, and
- offer a user interface for configuration of the analysis process (e.g., selecting target directories, etc.).

In addition to the proof-of-concept demonstration tool, important proposed objectives of Phase I included:

- identifying, documenting, and implementing methods for rapid file type determination,
- estimating acceptable performance bounds for background steganalysis (time and space),
- designing and documenting an application programming interface (API) for plug-in steganalysis modules, including a description of framework services and data structures, and
- establishing a testing environment and executing tests of the concept demonstrator.

Most of these objectives were retained (and achieved) during our Phase I effort. Interaction with the technical advisors at AFRL Rome caused us to de-emphasize file type detection, and as a consequence of this decision, we abandoned our plan to use machine learning techniques to create a reliable, accurate, and high-performing file type detector. We also focused exclusively on file creation and modification, leaving email for later consideration.

Work Carried Out

September 2004

The STTR contract to ECC and subcontract from ECC to UW-P were put in place and effort started at ECC and UW-P. It took a couple of days after the contract was in place to get students hired at UW-P, but this had no negative impact on progress.

We established a project wiki to support inter-site communication, making project documents readily available to all participants. The wiki is password protected to control access to project personnel.

As described in our proposal, the preliminary architecture for StegKit features a controller with plug-ins implemented as Windows DLLs, and a simple API consisting of two functions: `init()` and `detect()`. After working with this model, we provisionally added a third function - `typeof()`. We created some small programs to confirm that basic assumptions underlying the planned architecture, such as the ability to monitor file operations, true dynamic library loading and linking, were valid in the Windows environment. Analysis of the architecture identified some security and performance issues.

We collected information on file type detection and identified three possible approaches: (a) the basic Windows approach, mapping file extensions to application types, (b) the basic Unix approach of magic numbers/bytes, and (c) machine learning from examples.

Finally, we prepared briefing materials for the kickoff meeting scheduled for 07 October at Rome, NY.

October 2004

The kickoff meeting was held at Rome on 07 October. Discussion at the kickoff meeting indicated that some adaptation to our planned efforts would be helpful. This was neither surprising nor difficult to accommodate, but was a point at which we needed to make changes from our initial plan. The principal changes were (1) to redirect UW-P away from efforts to explore machine learning for file type detection; and (2) to increase the planned number of plug-ins of each type so as to provide greater insight into the feasibility of the plug-in architecture. The plan is now to emphasize the use of multiple plug-ins (both for file type detection and steganalysis) to exercise the plug-in architectural concept, giving insight into feasibility of the approach. UW-P refocused onto creation of plug-ins implementing well-known steganalysis algorithms.

UW-P delivered (to ECC) initial test versions of file type detectors for JPEG and GIF image file types that use file name extensions and magic bytes to type files. They also collected about 1G of file examples "from the wild" for testing, and set up four separate steganography programs to prepare "known bad" versions.

ECC implemented a controller that

- checks a startup directory for plug-ins
- loads any plug-ins detected and calls their init() function
- monitors specified directories for file creation
- copies files created in the specified directories to a work/quarantine area
- calls the loaded plug-ins against the files in the work area
- returns a "good/bad" call for each file

The controller does not currently distinguish between file type detection and steganalysis plug-ins. It therefore does not yet attempt to restrict calls to steganalysis plug-ins to files of an appropriate type.

We did encounter a technical issue in the plug-in API. Our initial plan was to have the controller component open each suspect file, then pass a handle to that open file to each plug-in as an argument to the typeof() function. This would minimize file manipulation overhead by amortizing the cost of a single file open/close over all invoked plug-ins. Unfortunately, it has proved to be quite complex to accomplish if the controller and plug-in are written in different languages, since each language has a language-specific representation of an open file. So, for example, C++ has a representation that differs

from Java, and it is not clear how to pass the C++ representation to a Java plug-in. Fortunately, this is not a critical issue for feasibility - premature optimization can be the enemy of good design. For the present, we are passing file names (with path) to the plug-ins, and require the plug-ins to do file open/close as needed.

November 2004

UW-P created initial test versions of file type detectors for JPEG and GIF image file types using file name extensions and magic bytes to type files. As these plug-ins were made available to the controller, we found some instances where the initial plug-in API definition was deficient, so it was updated. File type detection is now accomplished through a newly defined function `isOfType()`, analogous to `detect()` for steganalysis plug-ins. We clarified input and output parameter types and legal values and now require that the `detect()` function return a floating point value between 0.0 and 1.0 inclusive rather than a Boolean to accommodate statistical responses. Finally, we eliminated the `typeof()` function (which had provided a subset of the functionality required of `init()`).

The controller was enhanced to distinguish between file type detection and steganalysis plug-ins, and to apply only relevant analysis techniques based on the computed file type. UW-P updated their existing plug-ins to reflect the revised API definition.

December 2004

Most of our effort during December focused on completing the basic controller functionality. While this was primarily a matter of resolving issues surfaced by testing, we also added a simple user interface offering the following functions:

- specifying directories to monitor for new file creation
- starting and stopping the file creation monitoring thread
- turning logging on and off
- forcing an immediate scan of a single file or all files in a specific directory
- setting the threshold at which a file is considered "suspicious" (based on return values from steganalysis plug-ins)
- viewing a list of suspicious files

The controller currently does the following:

- checks a startup directory for plug-ins, loads any plug-ins detected and calls their `init()` function
- monitors any specified directories for file creation
- copies files created in the specified directories to a work/quarantine area
- calls the loaded plug-ins against the files in the work area
- checks the value returned from the steganalysis plug-ins against a user-defined threshold to determine if the file is "suspicious"
- clears all non-suspicious files from the work area

- reports suspicious files to the user
- (optionally) logs all activity

Most of the issues we have encountered in building the controller are system-level:

- detecting file creation/modification/deletion involves using an operating system service (true for both Windows and Unix)
- runtime discovery and invocation to plug-ins uses operating system calls and insight into parameter layout and passing conventions
- isolating file change detection from file analysis (to avoid causing the analysis process to introduce a bottleneck) is a threading/process issue
- detecting and recovering from plug-in failure also requires isolation through thread/process architecture

The current controller uses a threading model for isolation. We are finding the thread monitoring capabilities of our development environment to be somewhat limited, and are considering moving from threading to separate processes in some cases.

The plug-in API has proven robust so far, but has not had extensive testing with analysis plug-ins. We have discovered situations in which it would be helpful to have file type detectors return a numeric assessment rather than just a file type - for example, we have found situations in which image files lack "magic bytes" that the file type definition indicates they should contain. Technically, such files are not valid (e.g., are, strictly speaking, not really JPEG files), but are properly displayed by the tools we have employed, and so should be checked by the relevant analysis tools.

While we do not intend to devote any Phase I development effort to it, we have begun to give some thought to possible future work. One topic of discussion has been support for server-side use. The modularization of the system architecture appears to make it straightforward to retarget from our current client-side service orientation by simply replacing the file change detection component (and, of course, the user interface). On the server, the StegKit controller could be used as a module in a mail server (filtering emails before forwarding to individual clients), or as a filtering application within a proxy cache like Squid. By attaching to a cache, it would be possible to share the steganalysis facility without having to install on every user machine. A second area of concern is remote administration, allowing a centralized system administration group to configure and manage StegKit clients on end-user computers. We hope to develop some use cases to capture our discussions in these areas.

January 2005

With a working controller in place, efforts in January focused on plug-in development and testing. New steganalysis and file type detection plug-ins were provided by UWP, and proved useful in validating the operation of the controller (as well as performing their basic functions). The analysis plug-ins were developed by taking existing steganalysis

code (typically found on the Internet) and wrapping it to meet the plug-in API required by the controller.

This approach drew our attention back to issues of security. One of the plug-ins had an advertised flaw when used against valid images of a particular type (24 bit BMP)¹. However, it crashed when presented with images of a slightly different type (16 bit BMP). The wrapping process did not attempt to correct the error, so when a test file invoked the plug-in on a 16 bit BMP, it crashed. In the initial controller implementation, this crash propagated back to the controller and caused it to crash in turn.

We have also been reimplementing the controller functionality in Java for greater portability, so the crash isolation issue will be addressed in the update. Our Java implementation does rely heavily on JNI functionality to access operating system services, such as file creation notification.

We now have examples of plug-ins written in both C++ and C.

UWP has had a paper accepted for presentation at the 38th Annual Midwest Instruction and Computing Symposium, April 8-9, 2005.

February 2005

We discovered situations in which it would be helpful to have file type detectors return a numeric assessment rather than just a file type - for example, we have found situations in which image files lack "magic bytes" that the file type definition indicates they should contain. Technically, such files are not valid (e.g., are, strictly speaking, not really JPEG files), but are properly displayed by the tools we have employed, and so should be checked by the relevant analysis tools.

Reimplementation of the controller functionality in Java for greater portability continues. We are using an inexpensive (\$95) commercial development library, JNIWrapper, to reduce development time. JNIWrapper has no runtime license fees, so redistribution of StegKit has no impediments.

The project wiki is moribund - the last meaningful update was in November 2004. In talking with project members, it appears that the work has been effectively partitioned between ECC and UW-P, and that participants at each site find it easier to simply "walk down the hall" than to use the wiki. There is a fair amount of email traffic that probably could have been managed through the wiki, but we would have to consider the wiki experiment a failure to date.

We have created fewer steganalysis plug-ins than we had planned. Our approach has been to use existing open-source components, recast as plug-ins. Unfortunately, the code that

¹ "Note: This test will not work on 24-bit color images, because S-Tools hides the secret message a different way. However, with 24-bit images, a program is not required because these images are so rare their use would itself be suspicious"

we have found is filled with old software idioms that are proving difficult to reverse or translate. We anticipate that the production rate for steganalysis plug-ins will increase considerably in the next quarter.

March 2005

We completed the Java reimplementations of the StegKit controller. We also added new plug-ins for analysis of GIF files.

We prepared for and hosted at ECC on 24 March an interim review with participants from AFRL and speakerphone connection to UW-P. A beta version of StegKit (including a complete Windows install package and full source directories) was released to AFRL.

The interim review was most helpful in improving our understanding of the overall setting in which this project is placed. In particular, AFRL emphasized the value of being able to support steganalysis algorithm implementations that are not implemented as DLLs, and that may not match our current (and admittedly simple) model of returned information.

Based on feedback received at the interim review, we are revisiting the StegKit architecture to ensure ability to support already-developed steganalysis components available to AFRL, and to reflect our experience in creating the prototype.

Also discussed were other potential features and enhancements to the existing system, including (but not limited to):

- a more graceful response to changes in the threshold setting that would result in already analyzed files no longer exceeding the threshold - at a minimum, the user should be warned of the consequences.
- techniques for fusing data from multiple steganalysis plug-ins. This fusion could take place on several levels. In the past, we have discussed a "voting" approach to determining the likelihood of steganographic content, but other possibilities include getting detection information from one plug-in and content characteristics from another.
- richer response actions, such as selective alarms based on user role.
- performance issues, including the potential of executing plug-ins in individual threads.

April 2005

Based on feedback received at the interim review (see March status report), we designed and tested an approach for supporting non-DLL plug-ins.

The basic issue is that the StegKit controller architecture to this point has presumed that plug-ins will be implemented as DLLs (or, on Unix-like systems, as shared object files) exposing a specified API. While this works for the case where plug-ins are developed

with knowledge of the controller, it is less satisfactory for cases where there is an existing codebase developed without consideration of the specific controller/plug-in architecture. The design case was motivated by a projected commercialization of StegKit as a utility package analogous to anti-virus software - in that setting, the expectation of plug-ins developed to match a defined API is reasonable, even if the plug-ins are developed by a third party. However, an equally valid design case would be that described by AFRL, where there is a requirement to use existing steganalysis tool implementations without modifying the tested, working code to make it fit the specified StegKit DLL/API model.

There are basically four issues that must be handled: (1) discovery; (2) invocation protocol; (3) API mapping; and (4) additional (unanticipated) functionality.

Discovery: In the previous StegKit architecture, plug-ins were auto-discovered by searching a specified directory for DLLs. Coupled with monitoring of file creation events, this also makes it possible to dynamically incorporate new plug-ins into the overall functionality without stopping and restarting the controller. In the revised architecture, there must be a way to know where the plug-in functionality is provided.

Invocation protocol: When plug-ins are DLLs, they can be dynamically loaded and registered for use. The plug-in definition need not be available at the controller compile time. The COM-based DLL support in Windows (and similar shared object support in Unix) provides a means for the controller to find and invoke specific functions within a DLL. The StegKit plug-in API definition constrains the DLL functions so that there is no uncertainty regarding the invocation protocol. A similar capability must be provided for command line executables (which may take a variety of parameters, sometimes in flexible order) and Java jar files. In the case of Java jars, a strong presumption of the Java programming model is not satisfied, namely, that the jar file will be available at controller compilation time.

API mapping: The StegKit API is very simple. There are three functions, and any plug-in is required to provide two of them.² However, pre-existing candidate plug-ins, such as the stegdetect command line program, do not supply these functions directly. There must be a method for supplying a "virtual API" function from the capability of the target plug-in.

Additional (unanticipated) functionality: The StegKit API is also relatively impoverished in terms of what it expects from plug-ins. In particular, the controller tags files under consideration with a float between 0.0 and 1.0, intended to represent the likelihood that the file contains steganographic content. Many steganalysis algorithms, and the code that implements them, are capable of providing much more information. Stegdetect, for example, offers a guess as to what steganographic program was used to insert the surreptitious content. Other algorithms are capable of indicating the location of the hidden content, or even the detected content itself. There should be a way for these algorithms to supply this additional information to users, even though the existing StegKit model does not anticipate it.

² All plug-ins are required to supply an `init()` function. Plug-ins also supply either an `isOfType()` function or a `detect()` function depending on whether the plug-in is a file type detector or steganalyzer.

Fortunately, we have been able to generalize the StegKit architecture to accommodate a much wider range of plug-in components. Our specific new targets are self-contained executables that can be invoked from a command line (e.g., stegdetect, Under The Carpet) and Java class/jar files. We anticipate that the same techniques that we are developing can be used for Matlab programs, but have not confirmed this.

In the revised architecture, there is only slight change to the controller module itself. It continues to manage the process of detecting new file creation and application of file detection and steganalysis functions implemented as plug-ins. Plug-ins are no longer constrained to be DLLs implementing a specific API. Any impedance mismatch between the controller and the actual plug-ins is handled by a set of proxies or shims that act as transducers.

Instead of scanning for DLLs and loading them, on startup, the controller looks for what we're calling configuration files, each of which describes a single plug-in. A configuration file addresses each of the four issues discussed above. Based on the configuration file, the controller selects a proxy (e.g., a Java jar proxy), initializes it to handle interaction with the actual plug-in component, then treats the proxy as though it is the plug-in, making defined API calls and getting responses that are API-compliant.

The proxy exposes an API-compliant interface to the controller and maps the controller's function calls into invocations of the actual plug-in in accordance with the directions in the configuration file.

We have implemented demonstration cases for command line executables (stegdetect) and for Java jar files (locally written). Command line executables are invoked through a command interpreter, and Java jar functionality is accessed through reflection.

We have also revisited the literature describing existing steganalysis algorithms with the intent of better defining the content of configuration files. For each algorithm we are characterizing (to the extent that the available descriptions permit) the input parameters, output data, and target file type (e.g., JPEG, MP3).

May 2005

As a part of our literature review of existing steganalysis algorithms, we contacted some algorithm developers to determine the implementation language used for the software reported in their papers.

We prepared a version of StegKit that incorporated Java jar, Windows DLL, and command line plug-in launch directly from the controller, by incorporating the previously developed proxy code into the controller. A final distribution was prepared with both an installable Java-based StegKit and full source for the controller, team-developed plug-ins, and stegdetect (the third-party application that was used as a command line interface plug-in).

Results Obtained

In Phase I work we were successful in supporting Microsoft DLLs through the COM interface, a command line EXE through a proxy wrapper, and a Java application through reflection. It should be mentioned that each of these execution environments was engineered specifically for the individual application. This route is not suitable for a production framework and we have begun to analyze more flexible options.

Building the Phase I Framework to support steganalysis provided many learning experiences for our team. Our results include:

- The design and implementation of a Controller based architecture that supports multiple file type and steganalysis plug-ins through a simple API.
- Research, design and development of file type detector plug-ins that can be used to efficiently target a file with an appropriate steganalysis program. If an inappropriate steganalysis tool is used on a file we have observed undesirable behaviors including: crashes and the return of false positive or miss steganalysis results. The file type detection methods implemented or studied in Phase I include:
 - simple file type detection based on file extension (implemented),
 - file type detection based on magic bytes (implemented), and
 - file type detection based on signatures detection using the frequency of different byte values and identification of structures like color pallets, etc. (prototyped).
- Design and development of an architecture that supports the loading of an arbitrary number of file type and steganalysis plug-ins without recompiling the Controller. Plug-ins that conform to a simple API can be saved to a specific directory at any time. The Controller scans this directory at startup to maintain a current list of active plug-ins. This plug-in maintenance method could easily be extended to trigger on an interval or event basis.
- Design and development of a graphical user interface that permits an administrator to configure and control the Phase I framework. This control included such functionality as:
 - manual file scanning of a specified file system directory or individual file,
 - automatic background file scanning based on the operating system sending notification to the framework when files were created in a specified file system directory,
 - a simple “what-if” analysis tool that allowed filtering logged results to return the files that had specific estimated probability of steganographic content as determined by previous steganalysis.
- Investigation and implementation of a framework that includes the use of INI configuration files that define the interface between plug-ins and the Controller. The INI configuration files allow for a much wider variety of plug-in execution modes, inputs and outputs.

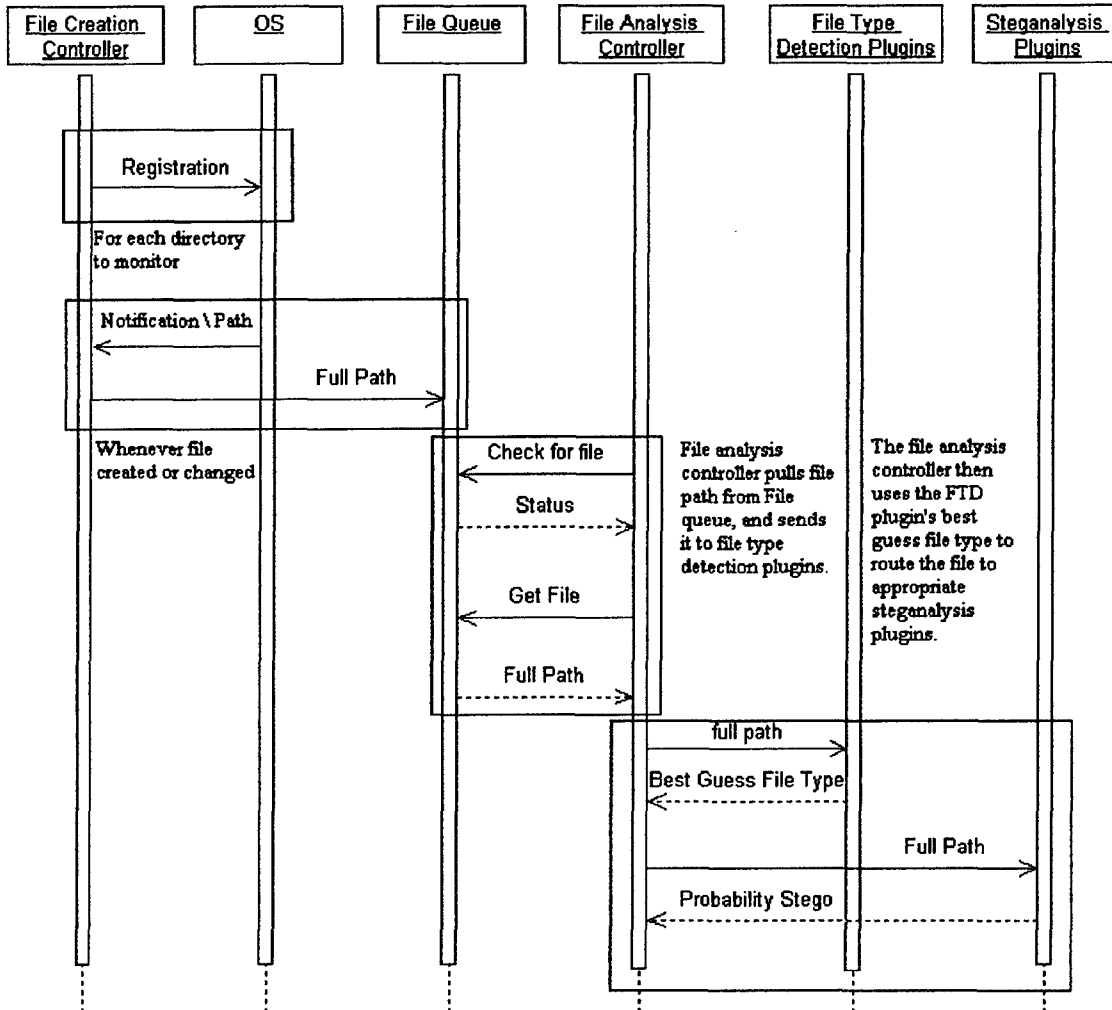

- Survey of the steganalysis literature and determination that a Phase II Framework will need to support multiple runtime environments in both command line (console) and GUI modes in order to integrate steganalysis from many different sources. The runtime environments include:
 - Java JVM
 - EXE
 - .NET
 - MATLAB®, and
 - Microsoft DLLs.
- Design and development of prototypes that support steganalysis plug-ins written in three different languages and run in three very different execution modes:
 - Microsoft DLL using COM to communicate input and output parameters,
 - Java using Java reflection, and
 - EXE command line programs using redirection of standard input and output

Below in Figure 1 is a high-level sequence diagram for the Phase I StegKit. The File Creation Controller and File Queue determine the existence of a new file and queue it for processing, respectively. The File Creation Controller is configured through the GUI to attend to any file activity in a particular part of the file system.

The Phase I controller has a great deal of knowledge of the overall StegKit process built into it. During its startup process, it searches the StegKit directory for plug-ins and loads and registers any that it finds. It initializes each plug-in, collecting information about the plug-in type and applicability. After initialization, the controller receives notification of new objects to be analyzed either from the user interface (manual requests to check a specific file or directory) or from the file creation monitor. It then runs all file type analysis plug-ins and, based on the results of that analysis, any relevant steganalysis plug-ins. Logging, notification, and quarantine operations are part of the controller.

We defined an API for plug-in components that would be invoked by a central controller. The Phase I API was very simple, requiring that (a) plug-ins be implemented as Windows Dynamic Link Libraries (DLLs), and (b) each plug-in supply two functions: `init()` and either `isOfType()` (for file type detection plug-ins) or `detect()` (for steganalysis plug-ins). The arguments and return values for the required functions were specified in the API. We demonstrated a working implementation of this architecture at the interim review held at ECC's facility.

Figure 1: Phase I controller sequence diagram

At that review, the Government representatives pointed out that it would be desirable if StegKit could accommodate previously created, or legacy steganalysis applications that were (a) not implemented as DLLs, and (b) did not support the defined StegKit API. Furthermore, these legacy steganalysis applications were implemented in a variety of technologies, including command line executables, Java class libraries (typically structured as jar files), and MATLAB® scripts, and could not be modified to match the StegKit plug-in implementation model or API. While this was somewhat different than what we had understood from the original topic description and our initial interactions, it is clearly a matter of interest that would greatly extend the utility of StegKit for users such as the Government technical advisors. Accordingly, we devoted a considerable amount of our remaining Phase I effort to investigating the issues.

We constructed proxies that wrapped the stegdetect command line executable program and an internally-prepared Java class, packaged in a jar file. The proxies were Windows DLLs offering the defined StegKit API. When an API function was called, the proxy

would respond appropriately, if necessary invoking functionality within its wrapped component and interpreting any response from that wrapped component. As an illustration, consider the stegdetect proxy.

- The stegdetect component has no functionality that corresponds to the StegKit init() API function, so all that functionality has to be provided by the proxy. The proxy simply responds with the plug-in type (steganalysis) and file type (JPG).
- For the detect() API function, the proxy receives the file path in the detect() call and uses it to build a stegdetect command line with the file path as the main argument, a parameter that controls output format (suppressing output when there is no detection), and output redirection to a known file name. The command is then executed in an inferior process, and the redirected output is examined for one or more asterisks enclosed in parentheses, which is how stegdetect rates the likelihood of steganographic content. The number of asterisks is mapped to a value between 0 and 1, which is then returned by the proxy as the value of the detect() call.

No change was needed to the controller - command line and Java jar plug-ins were accessible through proxies that satisfied the StegKit plug-in API while using the non-standard components.

As a proof-of-concept, our attempt to wrap non-compliant components was a success. However, the proxies/wrappers were hand-constructed, requiring programmer involvement to create. This would (probably) not be acceptable as a solution for the general legacy component problem - after all, if programming was an acceptable cost, then the legacy components could be modified to satisfy the StegKit API.

Estimate of Technical Feasibility

In Phase I, we demonstrated the feasibility of our general technical architecture featuring a centralized controller with plug-in components for file type detection and steganalysis. Placing overall control in a centralized component removes dependency on the specific details of any specific steganalysis algorithm, and, when coupled with file detection plug-ins, makes it possible to avoid unproductive computational expenditure that would be caused if steganalysis algorithms are run against suspect material for which they are inappropriate. We created an implementation of the architecture that used operating system services to detect file creation events, and then applied the type detection and analysis process to each changed file. By running as a service under the Windows operating system, the implementation was capable of monitoring all content encountered by a user as they browsed the Web.

In our Phase I proof-of-concept, plug-in components were required to provide a particular application programming interface (API), as suggested by the topic announcement. However, this requirement to comply with an API specification precluded the use of many existing implementations of steganalysis algorithms. First, since the existing implementations pre-dated the API specification, they would have to be revised to

comply with the specification. Second, and possibly more critical, the current API specification makes some strong assumptions regarding the nature of the analytical result, and these assumptions are not valid for all algorithms. Accordingly, practical considerations dictate that the StegKit architecture be enhanced to support "legacy" steganalysis implementations without requiring that they be rewritten.

Furthermore, because there are constant advances in steganography, StegKit must be capable of adapting to new approaches to data hiding, as well as incorporating improvements in steganalytical algorithms. The plug-in architecture enables the needed flexibility: new plug-ins may be provided to address new steganographic challenges, or to improve on existing algorithms. It is highly desirable that new and revised plug-ins be accessible without having to stop and restart the StegKit application - there should be no "reboot" required. We identified, but did not demonstrate in Phase I, an approach to "hot-plugging" that would detect and use new plug-ins without halting StegKit execution.

While the general feasibility of the approach has been established, there are still many issues to be addressed to produce a complete engineering prototype, suitable for deployment in an enterprise setting and ready for final product polish leading to commercial availability. We have identified the following as "next step" technical objectives:

1. Extend architecture to support "legacy" steganalysis algorithm implementations.
2. Support "hot-plug" extensibility.
3. Generalize and enrich the logging and reporting/notification capability.
4. Extend applicability by handling compressed file types (zip, gzip, etc.).
5. Support alternate file sources, such as mail servers, specifically Microsoft Exchange.
6. Improve the manageability of the system.

While not a specific technical objective, it would also be highly desirable to offer support for alternate operating system platforms, with Linux and Solaris as specific targets.

StegKit Final Phase I Release Notes

31 May 2005

There is one CD in the Final release. It contains both a Windows-compatible install package and source code for the StegKit controller (both Java and Visual Basic) and plug-ins (both file type detection and steganalysis).

Installation:

Insert the Install CD in a CD drive. Run SETUP.EXE from the CD. You'll be asked for a target directory - the default is \Program Files\jStegKit. An entry will be added to the Start menu.

Operations:

Startup

Select Start->Programs->jStegKit. This should launch the application, bringing up the main StegKit window, as shown below:

The slider between the windows sets the threshold at which an analyzed file will be quarantined.

Enable/Disable Logging

Typical first actions include activating logging by selecting Options->LogFile. (This is a toggle - if selected when checked, logging will be disabled.)

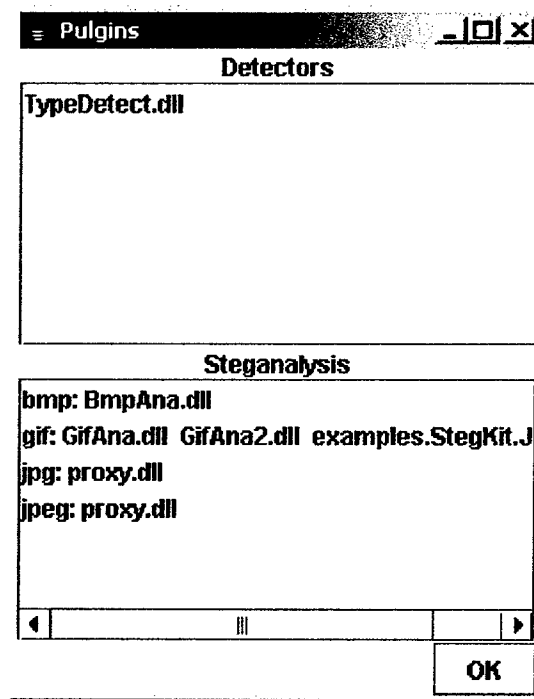

View Plug-Ins

You may select the "Register Dlls" option to see what plug-ins are currently available and loaded in StegKit.

The plug-ins are displayed in a separate window, and are distinguished as to whether they are file type detectors or steganalysis components. Steganalysis components are further identified by the type of file they have identified as being useful against.

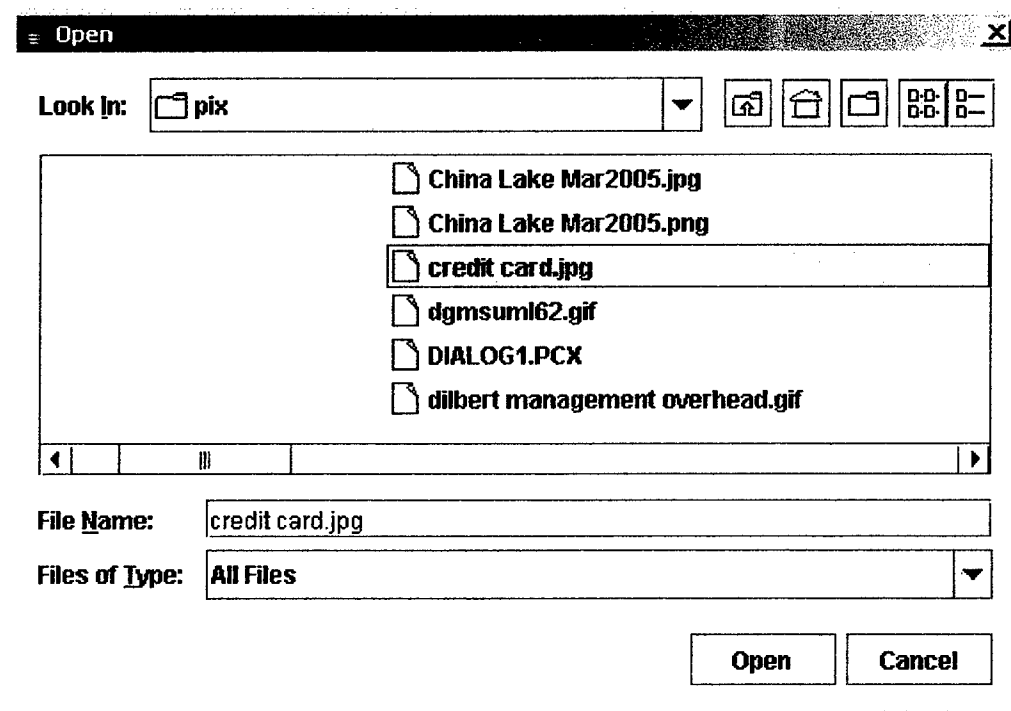

Click on the "OK" button to dismiss the plug-in listing.

Manually Scan Files or Directories

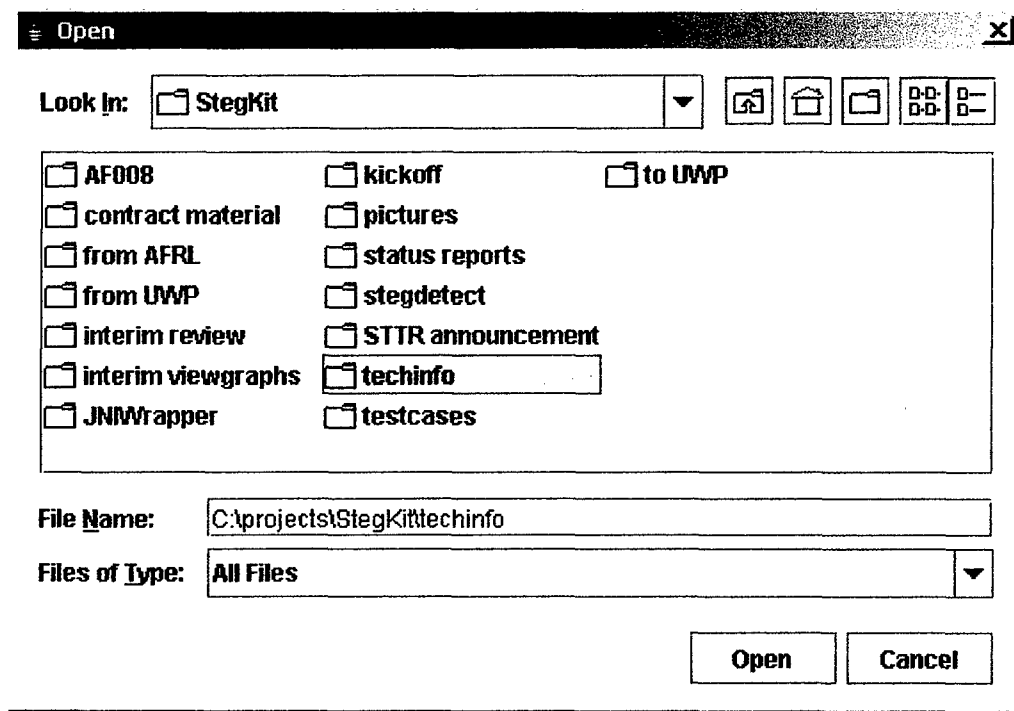

Individual files or specified directories may be scanned by using the Scan menu.

You will be offered a directory browser to select the desired file

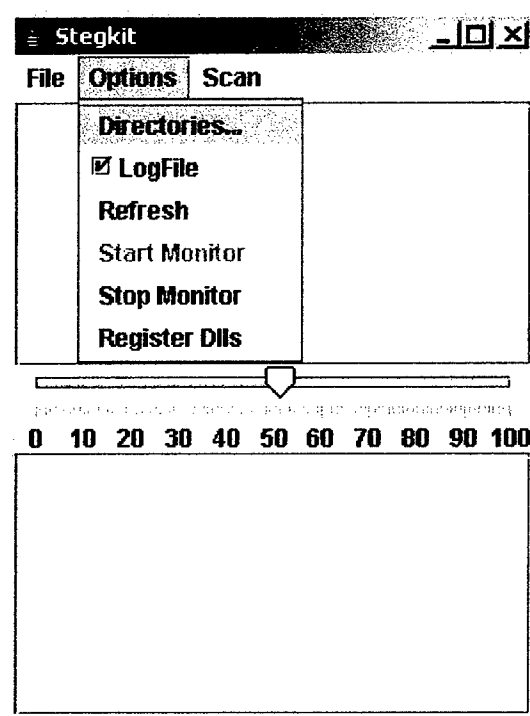

or directory, as appropriate.

Monitoring Directories

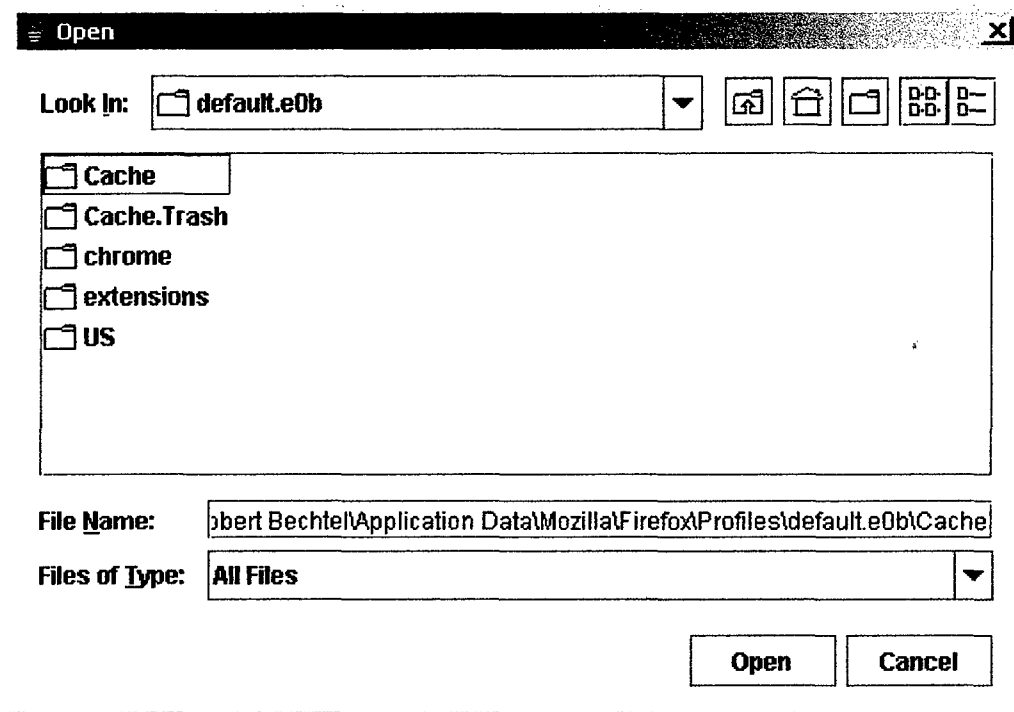

To monitor a directory, first select Options->Directories.

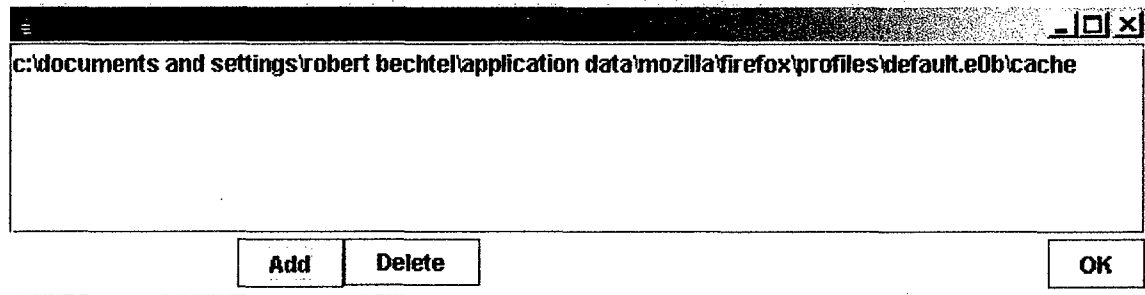

This will bring up a list of monitored directories (which should be empty on the first run).

Click on the Add button to bring up a directory browser, and browse to the directory to be monitored:

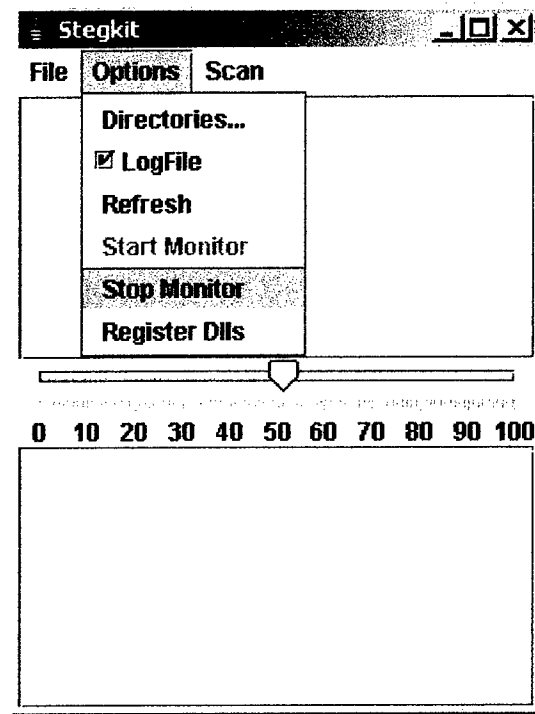

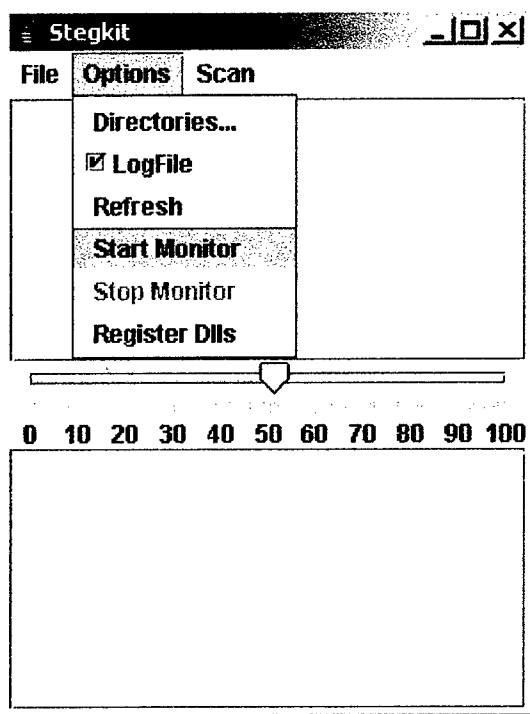

When the desired directory has been selected, click on Open to add the directory to the list of monitored directories.

Click on OK to return to the main StegKit window, or click on Add to monitor additional directories. If you want to remove a directory from monitoring, click on it in the directory list to select it, then click on the Delete button.

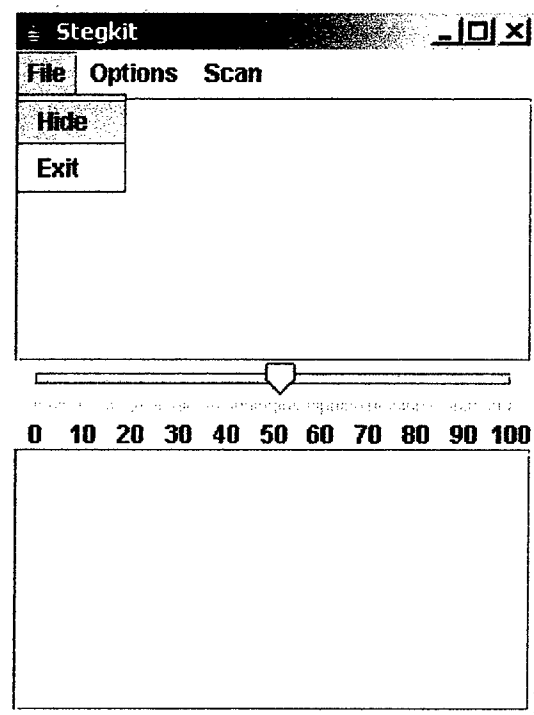

Activating and Deactivating Directory Monitoring

Monitoring can be turned off and on using the Options->Stop Monitor and Options->Start Monitor menu selections. Start Monitor will be inactive and gray when the monitor is running, and Stop Monitor will be inactive and gray when the monitor is stopped.

Hiding StegKit

While running, the StegKit window may be hidden (leaving an icon on the system tray) by selecting File->Hide.

To restore, right click on the icon in the system tray and select Show StegKit from the popup menu.

Exiting from StegKit

When StegKit window is visible: Select File->Exit.

When the StegKit window is hidden, right click on the StegKit icon in the system tray, then select Exit from StegKit from the popup menu.

Log files and quarantine:

The StegKit log file is named logfile.txt and is stored in the directory where StegKit was installed (default: \Program Files\jStegKit). It is just a text file, and may be viewed with any program capable of displaying text files.

The StegKit install directory also holds a subdirectory named Quarantine. Copies of quarantined files (those that exceed the user-set threshold) are placed here. The subdirectory also includes a file named quarn.txt that includes a cross-reference of all quarantined files.

NOTE: The quarantine area is sensitive to changes in the threshold. Increasing the threshold can remove a file from the quarantine area, if the threshold moves above the "probable detection level" associated with the file.

Distribution CD:

The root directory contains a Windows install of JStegKit. Simply execute setup.exe to run the installer.

```
\ (CD top level)
  0x0409.ini
  instmsia.exe
  instmsiw.exe
  isscript.msi
  jStegKit.msi
  setup.exe
  Setup.ini
```

The program files directory contains the executable files for the proxy-based JStegKit, and includes a StegDetect distribution (both source and executable).

```
\ (CD top level)\program files

```

The StegSource directory contains source code for a variety of pieces.

- BmpAna - BMP steganalysis
- GifAna - GIF steganalysis
- GifAna2 - another GIF steganalyzer
- jStegKit - jStegKit controller source
- proxy - proxy for StegDetect
- StegIntf - DLL interface for VB version of StegKit
- TypeDetect - file type detector plugins
- VBSteg - source for VB version of StegKit

StegKit Final Phase I Release Notes

31 May 2005

There is one CD in the Final release. It contains both a Windows-compatible install package and source code for the StegKit controller (both Java and Visual Basic) and plug-ins (both file type detection and steganalysis).

Installation:

Insert the Install CD in a CD drive. Run SETUP.EXE from the CD. You'll be asked for a target directory - the default is \Program Files\jStegKit. An entry will be added to the Start menu.

Operations:

Startup

Select Start->Programs->jStegKit. This should launch the application, bringing up the main StegKit window, as shown below:

The slider between the windows sets the threshold at which an analyzed file will be quarantined.

Enable/Disable Logging

Typical first actions include activating logging by selecting Options->LogFile. (This is a toggle - if selected when checked, logging will be disabled.)

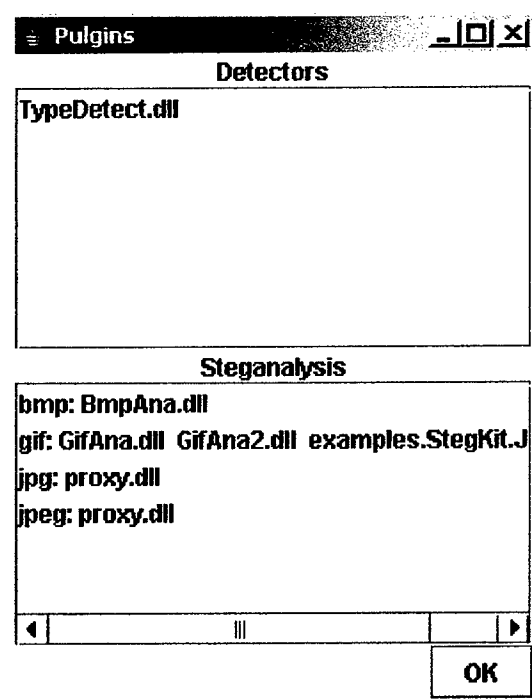

View Plug-Ins

You may select the "Register Dlls" option to see what plug-ins are currently available and loaded in StegKit.

The plug-ins are displayed in a separate window, and are distinguished as to whether they are file type detectors or steganalysis components. Steganalysis components are further identified by the type of file they have identified as being useful against.

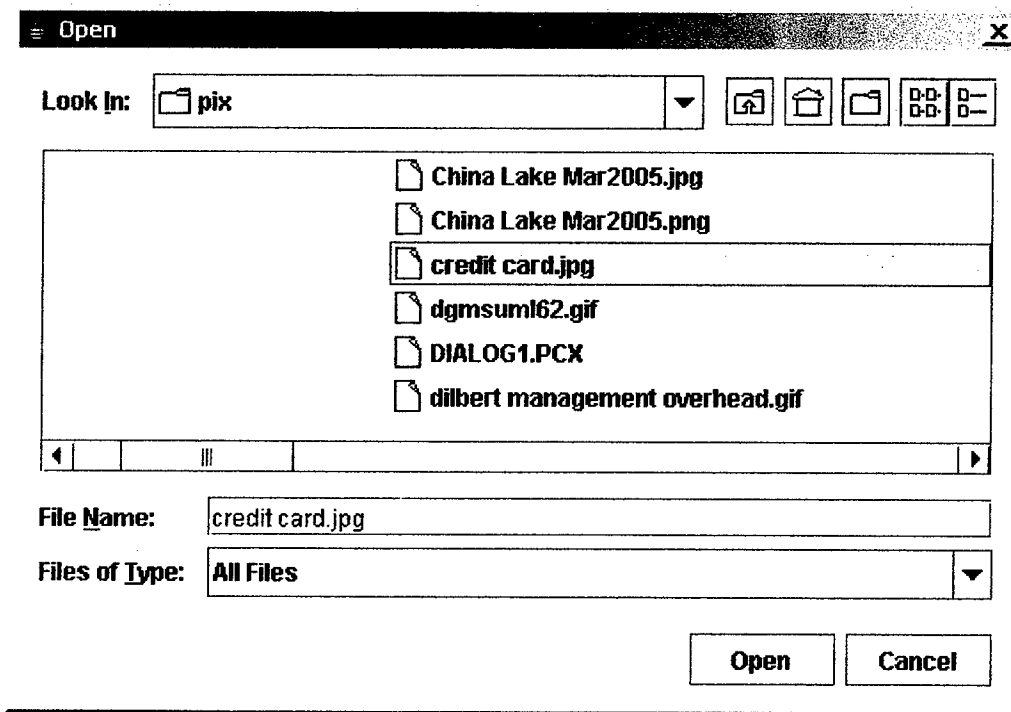

Click on the "OK" button to dismiss the plug-in listing.

Manually Scan Files or Directories

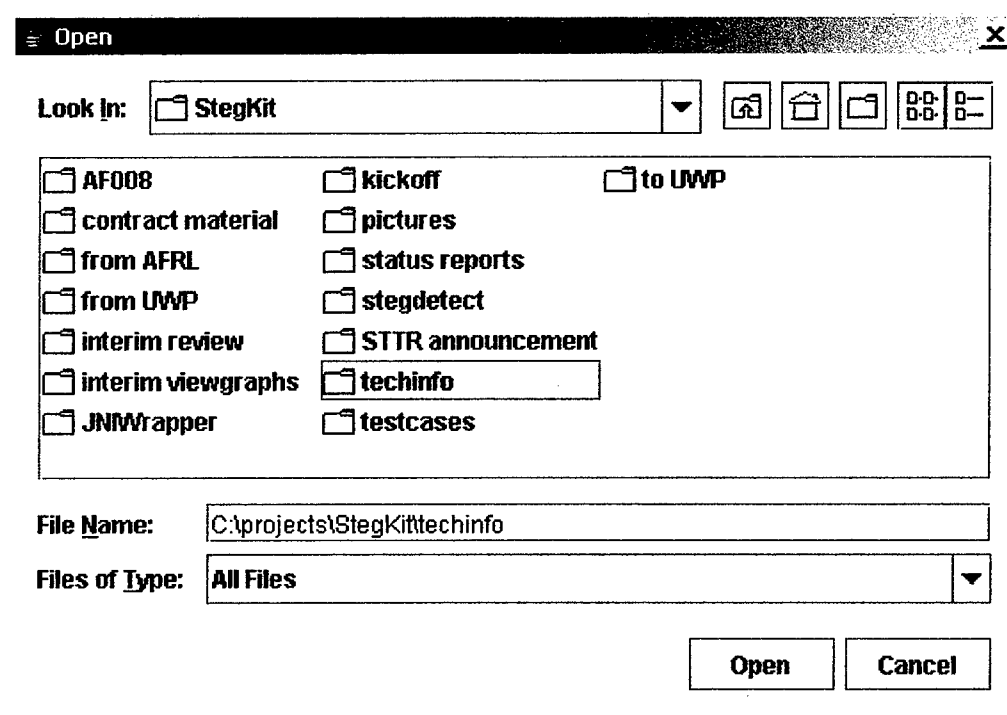

Individual files or specified directories may be scanned by using the Scan menu.

You will be offered a directory browser to select the desired file

or directory, as appropriate.

Monitoring Directories

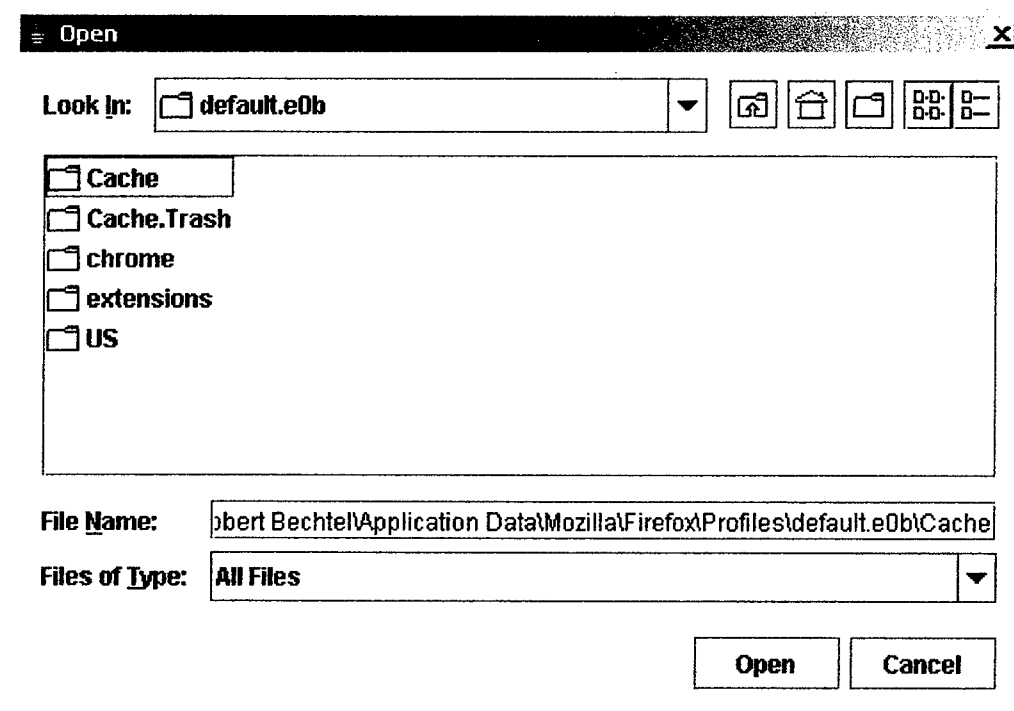

To monitor a directory, first select Options->Directories.

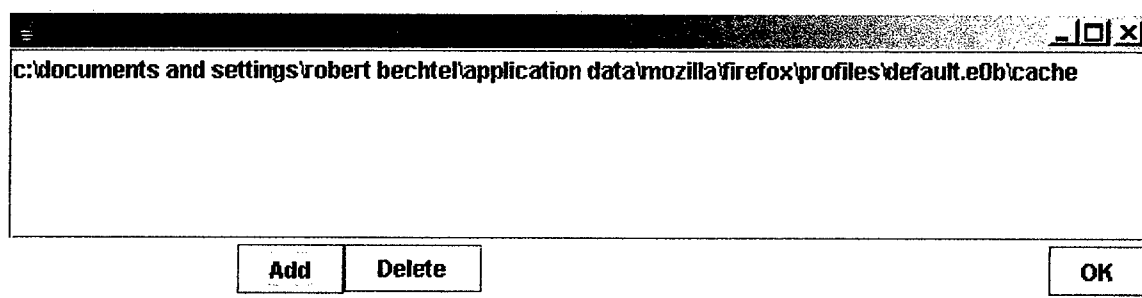

This will bring up a list of monitored directories (which should be empty on the first run).

Click on the Add button to bring up a directory browser, and browse to the directory to be monitored:

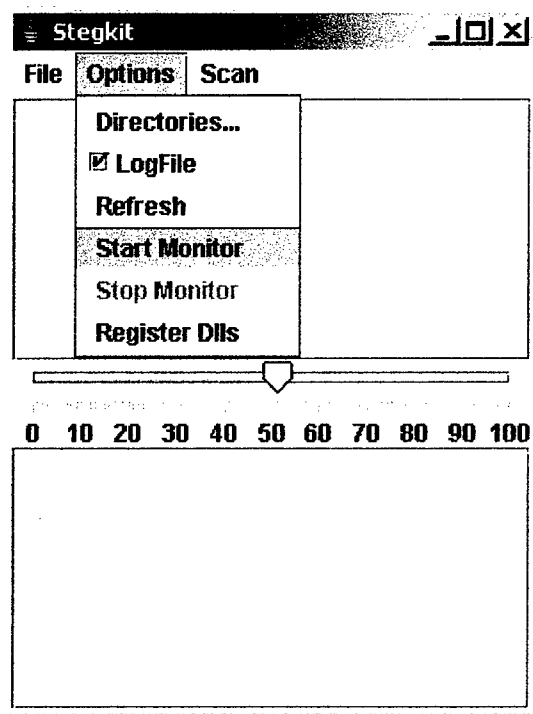

When the desired directory has been selected, click on Open to add the directory to the list of monitored directories.

Click on OK to return to the main StegKit window, or click on Add to monitor additional directories. If you want to remove a directory from monitoring, click on it in the directory list to select it, then click on the Delete button.

Activating and Deactivating Directory Monitoring

Monitoring can be turned off and on using the Options->Stop Monitor and Options->Start Monitor menu selections. Start Monitor will be inactive and gray when the monitor is running, and Stop Monitor will be inactive and gray when the monitor is stopped.

Hiding StegKit

While running, the StegKit window may be hidden (leaving an icon on the system tray) by selecting File->Hide.

To restore, right click on the icon in the system tray and select Show StegKit from the popup menu.

Exiting from StegKit

When StegKit window is visible: Select File->Exit.

When the StegKit window is hidden, right click on the StegKit icon in the system tray, then select Exit from StegKit from the popup menu.

Log files and quarantine:

The StegKit log file is named logfile.txt and is stored in the directory where StegKit was installed (default: \Program Files\jStegKit). It is just a text file, and may be viewed with any program capable of displaying text files.

The StegKit install directory also holds a subdirectory named Quarantine. Copies of quarantined files (those that exceed the user-set threshold) are placed here. The subdirectory also includes a file named quarn.txt that includes a cross-reference of all quarantined files.

NOTE: The quarantine area is sensitive to changes in the threshold. Increasing the threshold can remove a file from the quarantine area, if the threshold moves above the "probable detection level" associated with the file.

Distribution CD:

The root directory contains a Windows install of JStegKit. Simply execute setup.exe to run the installer.

```
\ (CD top level)
  0x0409.ini
  instmsia.exe
  instmsiw.exe
  isscript.msi
  jStegKit.msi
  setup.exe
  Setup.ini
```

The program files directory contains the executable files for the proxy-based JStegKit, and includes a StegDetect distribution (both source and executable).

The StegSource directory contains source code for a variety of pieces.

- BmpAna - BMP steganalysis
- GifAna - GIF steganalysis
- GifAna2 - another GIF steganalyzer
- jStegKit - jStegKit controller source
- proxy - proxy for StegDetect
- StegIntf - DLL interface for VB version of StegKit
- TypeDetect - file type detector plugins
- VBSteg - source for VB version of StegKit
