14. ABSTRACT (Maximum 200 words) On-component bonded repairs routinely encounter temperature limitations due to safety considerations and the presence of vulnerable materials or systems in the repair vicinity, such as elastomers and wiring. Due to these limitations, engineers desire the capability to cure epoxy adhesives at temperatures lower than those recommended by the manufacturers. Cytec Engineered Materials' FM 73M and 3M Company's AF 163-2M as well as Henkel's Hysol EA 9628 and Hysol EA 9696 adhesives were evaluated using cure cycles at 200°F and 180°F. Alternate cure times were identified via differential scanning calorimetry to optimize curing at 200°F and 180°F. Tensile lap shear, floating roller peel, and climbing drum peel tests were used to evaluate the corresponding bond strengths. Results obtained in this study proved curing the adhesives at 200°F and 180°F was feasible but led to reduced adhesive mechanical properties.

PREFACE

This report covers work performed by AFRL/MLSA and the University of Dayton Research Institute (UDRI) from June 2002 until December 2005. This work funded AFRL/MLSA and conducted under contract F33615-00-D-5600 Delivery Order 0001. The work was administered under the direction of the Materials Integrity Branch of the Systems Support Division, Air Force Materials and Manufacturing Directorate, Air Force Research Laboratory, Wright-Patterson Air Force Base, Ohio. Mr. James J. Mazza was the contract monitor. The Air Force Technical Leads on this program were Mr. James Mazza and Dr. Brett Bolan. The UDRI Contract Program Manager was Mr. Roger Rondeau. The UDRI Technical Lead was Mr. Dan McCray.

Ms. Kara Storage is thanked for performing a portion of the differential scanning calorimetry testing. Ms. Molly Brown and Ms. Kelly Feirstine, Southwestern Ohio Council for Higher Education (SOCHE), are thanked for assistance performing the mechanical testing in this program.

1 BACKGROUND

Adhesive manufacturers provide recommended cure cycles for their adhesive materials. Several commonly used aerospace structural epoxy film adhesives have a recommended optimal cure cycle of 60 minutes at 250°F under 35-40 psi positive pressure. Examples include Cytec Engineered Materials' FM 73M, 3M Company's AF 163-2M and Henkel's products Hysol EA 9628 and Hysol EA 9696. These materials are commonly used at Air Force Air Logistic Centers (ALCs) for structural repair bonding. Although manufacturers recommend 60 minutes at 250°F to fully cure the above-mentioned adhesives, repaired aircraft components can have maximum temperature limitations below 250°F that prevent the recommended cure cycles from being utilized. ALC engineers would like the option of using lower-temperature cure cycles for these adhesives, despite the increase in cure time, as long as acceptable mechanical strengths can be obtained. Therefore, alternate cure cycles for these commonly used adhesives were defined at 200°F and 180°F. Results of mechanical testing at these alternate temperatures were compared to results obtained from specimens bonded using the manufacturers' recommended cure cycle.

2 TEST PROGRAM

Alternate cure cycles were defined and evaluated for the following 250°F-curing epoxy film adhesives: (1) FM 73M, 0.06 pounds per square foot (psf), (2) AF 163-2M, 0.06 psf, (3) EA 9628, 0.06 psf, and (4) EA 9696, 0.06 psf. Initially, differential scanning calorimetry (DSC) was performed on each adhesive to define alternate cure times for temperatures of 180°F and 200°F. Once the alternate cure cycles were defined, mechanical testing was performed on specimens cured using these alternate cure cycles to determine the effects of the alternate cure cycles on bond strength.

2.1 Differential Scanning Calorimetry (DSC) Testing

DSC is a common thermal analysis technique utilized to measure the temperature/heat flow associated with transitions (e.g. glass transition temperature (T_g), melting, crystallization) and chemical changes (e.g. polymerization) in polymeric materials as a function of temperature and time¹.

A DSC instrument measures the amount of energy required to maintain a sample at a programmed temperature. For uncured epoxy-based adhesives, as the temperature increases, the material undergoes polymerization, generating heat due to the exothermic nature of the chemical reactions occurring. This is displayed by the DSC instrument as a peak in a heat flow versus temperature curve, the area under which represents the energy generated during the curing process. If a sample is only partially polymerized (e.g. due to a lower temperature cure cycle), then only a portion of the energy will be released (seen as a smaller peak). Thus, the heat released during a DSC test can be used as a measure of the degree of cure.

For this study, a TA Instruments DSC model Q100 was used to investigate the effect of the alternate cure schedules on the thermo-physical properties of the specified adhesives. A testing rate of 10°C/min was used for all dynamic scans, including the baseline determination for each adhesive. It was assumed, for all adhesives except FM 73M, the measured exotherms obtained during baseline runs represented the energy released for a fully (100%) cured adhesive. However, for FM 73M, the energy evolved during the one-hour isothermal cure at 250°F (i.e.

$\Delta H_{\text{isothermal}} = 216 \text{ J/g}$ from Table 2) was taken to represent the energy released for a fully (100%) cured adhesive. This was necessitated because the dynamic baseline run yielded a lower total exotherm value (203 J/g), possibly as a result of different/preferred chemical reactions occurring during this cure cycle. The FM 73M adhesive was beyond its stated shelf-life (although continually stored below -20°F), and this could be a contributor to the observed phenomenon as well. This will be further investigated in the future.

For the alternate cure cycles, the resins were rapidly heated to the isothermal hold temperature (in less than 3 minutes) and, therefore, it was not believed any measurably significant chemical reaction occurred during this time. In analyzing the alternate cure cycles, the areas under the curve (heat flow versus temperature) during the isothermal segment were quantified and compared to the results obtained from the baseline run for that adhesive. The ratio of these two quantities represents the extent of polymerization (curing) that occurred during the alternate cure cycle. For example:

$$\frac{\text{Alternate cure (EA 9696-8 hours @ } 180^{\circ}\text{F)}}{\text{Baseline (EA 9696)}} = \frac{\Delta H_{\text{isothermal}}}{\Delta H_{\text{R}}} = \frac{168 \text{ J/g}}{231 \text{ J/g}} \sim 73\%$$

This denotes that an 8-hour cure at 180°F results in EA 9696 adhesive that is approximately 73% cured.

After each baseline and alternate cure cycle experiment, the samples were rapidly cooled to room temperature (70°F) then dynamically scanned at 10°C/min to determine the residual heat of reaction ($\Delta H_{\text{residual}}$) as well as the materials' glass transition temperatures (T_g). Throughout this study, T_g was determined as the inflection point (I) of the thermal curve.

2.2 Mechanical Testing

In order to determine the effect of altering the cure cycle on adhesive bond strength, tensile lap shear², floating roller peel³, and honeycomb climbing drum peel⁴ tests were conducted. Adherends used for lap shear and floating roller peel testing were composed of bare Al 2024-T3 that were phosphoric acid anodized⁵ and primed with Cytec Engineered Materials BR 127 bond primer. Climbing drum peel specimens were fabricated from bare Al 2024-T3 face sheets bonded to 7.9-1/4-40(5052) core (MIL-C-7438⁶). The climbing drum peel facesheets were treated using P2 paste acid etch and primed with BR 127 primer. The P2 paste acid etch process followed the P2 tank process⁷ except the acid was mixed with Cab-O-Sil silica filler (130 mL acid:14.75 g Cab-O-Sil), applied via a brush for 25 minutes, then rinsed with water. The aluminum core was cleaned with an alkaline cleaner and rinsed with water prior to bonding. BR 127 primer was applied via a Binks 105 spray gun to a nominal thickness of 0.2 mil (0.0002 inch), dried for 30 minutes at ambient laboratory temperature (70°F), then cured for 60 minutes at 250°F in an air-circulating oven.

The matrix for mechanical testing is shown in Table 1. Specimens were bonded with each adhesive using alternate cure cycles derived from the DSC test results in Table 2. Actual cure times varied for each adhesive and were based on the apparent time at which cure was completed (Table 2) with additional time added to ensure cure was completed. Test results obtained with the alternate cures were compared to results obtained using the manufacturers'

recommended cure cycle of 60 minutes at 250°F. All bonding was conducted in a portable autoclave (lap shear and floating roller peel specimens) or hydraulic press (climbing drum peel specimens) using 35 psi positive pressure. Test panels were machined into specimens and tested according to Table 1. Dry specimens were tested after a 10-minute exposure to temperature. Wet specimens were tested after 4-minute exposure to temperature.

Table 1: Mechanical Test Matrix for the Evaluation of Alternate Cure Cycles

Adhesive	Cure Cycles	Number of Specimens per Condition					
		Lap Shear			Roller Peel		Climb Drum Peel
		70°F	180°F-dry	180°F-wet*	-65°F	70°F	70°F
EA 9628	1 hr @ 250°F	5	5	5	5	5	6
	4 hr @ 200°F	5	5	5	5	5	6
	8 hr @ 180°F	5	5	5	5	5	6

	6 hr @ 200°F	5	5	5	5	5	6
	8 hr @ 180°F	5	5	5	5	5	6

Note: * "wet" specimens were exposed to 140°F and 98% RH for 60 days prior to testing

3 RESULTS

Summarized results of the DSC and mechanical testing are shown in this section. A complete record of the DSC scans is presented in Appendix A. Complete results of the mechanical testing are shown in Appendix B.

3.1 Differential Scanning Calorimetry (DSC) Testing

Summarized results of the DSC testing are shown in Table 2. In general, the adhesives evaluated were found to exhibit similar thermal curing characteristics; longer times at lower temperatures were required to achieve a cured state (albeit with lower percent chemical conversion). At a cure temperature of 200°F, all four adhesives achieved similar cure states (i.e. T_g and % cure close to those obtained following the manufacturer's recommended cure schedule of one hour at 250°F), but with FM 73M accomplishing this in significantly less time. For a cure temperature of 180°F, FM 73M appears to not only have the ability to cure more quickly but also more fully than the other three adhesives.

3.2 Mechanical Testing

Results of the mechanical testing are shown in Table 3. All failure modes are cohesive (within the adhesive layer) unless otherwise noted. Mixed failure modes were a combination of adhesive and cohesive failures. Adhesive failures occurred at the primer-adhesive interface. Tensile lap shear results do not appear to be drastically reduced due to the reduced cure

temperatures. However, floating roller peel strength and climbing drum peel torques appear to be reduced due to the lower-temperature cures. The extents of the strength and torque reductions are discussed in more depth in Section 3.3.

Table 2: DSC Results for AF 163-2M, EA 9696, EA 9628 and FM 73M

Cure Cycle	Property	AF 163-2M	EA 9696	EA 9628	FM 73M
Baseline (10°C/min to 250°C (482°F))	Heat of Reaction from Dynamic DSC test ($\Delta H_R = \text{J/g}$)	176	231	272	203 ⁴
	Resultant T_g	214°F (101°C)	216°F (102°C)	225°F (107°C)	165°F (74°C) ⁴
1hr @ 250°F (121°C)	Energy evolved during isothermal hold ($\Delta H_{\text{isothermal}} = \text{J/g}$) ¹	179	231	275	216 ³
	Apparent time at which cure was completed (min) ²	33	25	27	35
	T_g	234°F (112°C)	239°F (115°C)	243°F (117°C)	201°F (94°C)
	Residual heat of reaction after isothermal cure ($\Delta H_{\text{residual}} = \text{J/g}$)	5	0	0	3
	% cure [$(\Delta H_{\text{isothermal}}/\Delta H_R)*100$] = J/g	97	100	100	99+
6 hrs @ 200°F (93°C)	Energy evolved during isothermal hold ($\Delta H_{\text{isothermal}} = \text{J/g}$) ¹	157	209	241	199
	Apparent time at which cure was completed (min) ²	204	179	158	113
	T_g	234°F (112°C)	232°F (111°C)	235°F (113°C)	228°F (109°C)
	Residual heat of reaction after isothermal cure ($\Delta H_{\text{residual}} = \text{J/g}$)	15	25	29	21
	% cure [$(\Delta H_{\text{isothermal}}/\Delta H_R)*100$] = J/g	89	90	89	92
8 hrs @ 180°F (82°C)	Energy evolved during isothermal hold ($\Delta H_{\text{isothermal}} = \text{J/g}$) ¹	134	168	189	174
	Apparent time at which cure was completed (min) ²	350	350	295	216
	T_g	207°F (97°C)	208°F (98°C)	214°F (101°C)	212°F (100°C)
	Residual heat of reaction after isothermal cure ($\Delta H_{\text{residual}} = \text{J/g}$)	31	47	46	35
	% cure [$(\Delta H_{\text{isothermal}}/\Delta H_R)*100$] = J/g	76	73	69	81

Notes

- ¹ These values are estimates and subject to errors of up to 3%. This is attributable to the uncertainty in determining the precise time at which significant amounts of chemical reactions begin and end (i.e. where to place the markers for analyzing the area under the "peak"). In the isothermal mode of operation, the DSC instrument becomes less sensitive to chemical reactions that may be occurring at slow rates over long periods of time.
- ² Completion times are estimated as the amount of time to achieve 90% of the maximum chemical conversion level for the particular cure condition. The completion times are subject to the same errors (with the same rationale) as those mentioned in Note 1.
- ³ For FM 73M, it was assumed the energy evolved during the isothermal cure of 1 hour at 250°F (i.e. $\Delta H_{\text{isothermal}} = 216 \text{ J/g}$) represents the energy released for a fully (100%) cured adhesive and not that evolved during the baseline dynamic DSC test (i.e. $\Delta H_R = 203 \text{ J/g}$).
- ⁴ These values are below those claimed by the manufacture, which might be attributed to the adhesive being beyond its stated shelf life (despite being constantly stored at or below -20°F).

Table 3: Mechanical Test Results

Adhesive	Cure Cycles	Average Strength					
		Lap Shear (psi)			Roller Peel (pli)		Climb Drum Peel (in*lb/in torque)
		70°F	180°F-dry	180°F-wet*	-65°F	70°F	70°F

* "wet" specimens were exposed to 140°F and 98% RH for 60 days prior to testing

^m specimens exhibited a mix of cohesive and adhesive failure modes

3.3 Effect of Reduced-Temperature Cures on Bond Strength

The main concern with using a low-temperature alternate cure cycle is the possibility of losing bond strength. In order to assess the effects of using the alternate cure cycles, the mechanical strengths from Table 3 were used to generate normalized strength charts for each adhesive to determine the knockdown for each mechanical test and testing condition due to the alternate cure cycle. Normalized strengths were determined for each test condition with each adhesive using the following equation:

$$\text{Normalized strength (\%)} = (\text{Strength}_{\text{alternate cure}}) / (\text{Strength}_{1 \text{ hr @ } 250^\circ\text{F cure}}).$$

The normalized strength chart for EA 9628 is shown in Figure 1. Curing the adhesive at 200°F or 180°F did not adversely affect lap shear strength under any conditions. However, the lower-temperature cure cycles produced reduced floating roller peel strengths and climbing drum peel torques. Curing at 180°F reduced peel strengths (~50-60% of original strength) more than curing at 200°F.

The normalized strength chart for EA 9696 is shown in Figure 2. Curing the adhesive at 200°F or 180°F did not adversely affect lap shear strength at RT or 180°F-wet. However, there was a reduction in 180°F-dry lap shear strength due to low-temperature curing. The lower-temperature cure cycles produced slight reductions in -65°F floating roller peel strength. Floating roller peel testing and climbing drum peel testing conducted at 70°F showed reduced bond strengths and torques due to lower-temperature curing. As with EA 9628, curing at 180°F reduced the bond strengths more than did curing at 200°F.

Figure 1: Effect of Alternate Cure Cycle on Normalized Strength for EA 9628

Figure 2: Effect of Alternate Cure Cycle on Normalized Strength for EA 9696

The normalized strength chart for FM 73M is shown in Figure 3. Curing the adhesive at 200°F or 180°F did not adversely affect lap shear strengths under any conditions. There was a substantial reduction in both floating roller peel strength and climbing drum peel torque due to reducing the cure temperature.

The normalized strength chart for AF 163-2M is shown in Figure 4. Curing the adhesive at 200°F or 180°F did not adversely affect lap shear strength at RT or 180°F-wet, although 180°F-dry lap shear strength was reduced due to low-temperature curing. Unlike the other film adhesives, AF 163-2M exhibited a smaller reduction in floating roller peel strength and climbing drum peel torque due to lower-temperature curing.

Figure 3: Effect of Alternate Cure Cycle on Normalized Strength for FM 73M

Figure 4: Effect of Alternate Cure Cycle on Normalized Strength for AF 163-2M

When comparing Figures 1-4, it appears AF 163-2M retained floating roller peel and climbing drum peel properties better than the other adhesives when cured at 200°F and 180°F. On the other end of the spectrum, FM 73M appeared to lose peel properties more easily than the other evaluated adhesives when cured at 200°F and 180°F, even though FM 73M had a higher percent cure as determined by DSC.

4 CONCLUSIONS

DSC data evaluating alternate low-temperature cures were generated on four commonly used 250°F-cure epoxy film adhesives: EA 9628, EA 9696, FM 73M and AF 163-2M. According to DSC results, curing the adhesives at 200°F for 6 hours provided thermo-physical properties (T_g and degree of cure) similar to those obtained when using the manufacturers'

recommended cure temperature of 250°F for one hour. Curing at 180°F provided properties substantially less than those obtained using the 250°F cure temperature.

Tensile lap shear, floating roller peel, and climbing drum peel specimens were fabricated using the evaluated adhesives with 250°F, 200°F, and 180°F cure temperatures. Tensile lap shear strength was not appreciably reduced for any of the adhesives cured at 200°F. Reduction in lap shear strength was observed for EA 9628, EA 9696, and AF 163-2M when testing at elevated temperature after curing at 180°F. Floating roller peel and climbing drum peel test results were significantly reduced due to curing at temperatures lower than the recommended 250°F. Peel strengths obtained when curing FM 73M and EA 9628 at 200°F & 180°F were reduced by 40-50% when compared to peel strengths obtained using a 250°F cure. EA 9696 and AF 163-2M fared better when cured at 180°F & 200°F, experiencing peel strength losses around 20-30% when compared to specimens cured at 250°F.

Although curing the evaluated adhesives at 200°F instead of 250°F appears to provide acceptable results, it should be noted this adhesive evaluation was not comprehensive. This evaluation was meant as an initial assessment of reduced-temperature curing of typical “250°F-curing” modified epoxy film adhesives. No work was performed to evaluate the effects of reduced-temperature cures on adhesive characteristics such as chemical resistance (e.g. jet fuel, hydraulic fluid, solvents, etc.), bond durability, or stress/strain relationships. All of these effects should be understood prior to implementing reduced-temperature cures for bonded structures.
