PRODUCIBILITY EVALUATION CRITERIA

Cost Estimating Computer Programs - Manual

Providing guidance for use of several computer programs which have been developed by SNAME Panel SP-4 for determining the cost of construction of a ship or portion of a ship, or for determining which of several design alternatives will be the least expensive to build and which will be the best choice to select, considering all elements of the decision-making process.

Chapter 1 - INTRODUCTION

This manual has been prepared to describe the use of a number of computer programs that have been developed for evaluating the producibility and desirability of different ship design alternatives. These programs are included on a floppy disk which accompanies this manual. The background of their development is described in reference 1 and will not be repeated here.

This manual is intended as a "How-To" document and consequently will be presented primarily in the second person as if giving hands-on advice, looking over your shoulder.

The description which follows assumes familiarity with entering data into personal computers. Specifically, rather than stating "press the enter key" each time that this statement is required, this will be assumed to be understood whenever the direction to "enter" data is given. The commands to be entered will be shown in this manual in bold capitals, but when actually entering commands or data, lower case may be used.

Whenever a line on a screen asks for entry of a single letter choice from several listed possibilities, such as Y or N for yes or no, the default choice will be bracketed by the <> symbols. In such cases, the enter key may be processed to select the default choice.

The floppy disk which accompanies this manual includes the GW-BASIC application on the main directory. The programs on the disk are filed in one of the three subdirectories, which are identified as "COST", "PROD" and "DEC". Chapter 2 of this Manual addresses the use of the programs in the COST subdirectory, Chapters 3 and 4 address the programs in the PROD subdirectory and Chapter 5 describes the use of the DEC subdirectory files. All of the programs on the disk are either written in GW-BASIC and run using that application program or they are spreadsheets in LOTUS 123 format.

The GW-BASIC statements that are used in the programs in the PROD subdirectory are written out in the Appendix. The programs in the DEC subdirectory are identical in concept and use, varying only in the criteria that are considered within the programs. The DEC program statements, as well as the PROD program statements, can be obtained from within the GW-BASIC shell by loading the individual program and typing "LIST".

The producibility criteria and decision-making criteria used in these programs are those which were determined during the research described in Reference 1. The programs provided with this manual use the weighting factors that were obtained during that research effort. Chapter 4 provides detailed instructions on the use of the computer programs used to determine those weighting factors and to reevaluate them when necessary.

If you have any questions concerning how to use or to modify these programs for your specific use, call 1-800-347-7689.

This Page is Blank Intentionally

Chapter 2- THE COST ESTIMATING COMPUTER PROGRAMS

GENERAL

The programs described in this chapter are located in the COST subdirectory. These programs are used for estimating the manhours and cost for constructing what the design describes. By applying these programs to each alternative design of a particular aspect of a ship design that is under consideration% you will develop an estimate of the manhours and cost to build each of them. By definition, the alternative that requires the least manhours and cost will be the most producible.

The cost estimating computer programs are in spreadsheet format and are designed for use with Lotus 123 Release 2.0 or later. Translation of the programs to several other spreadsheet application programs has been successfully accomplished. Use of the programs in any application program that accepts 123 data input should present no problem. To obtain more detail on the use of these programs, enter "CD\COST", and then "README".

The basic concept of the cost estimating programs is to go through on paper, all of the processes by which the design under evaluation will be build identifying the quantity of work that will be required for each of those processes. For various types of work there are different parameters which determine how many manhours will be required to complete the process. Thus, for welding, the length of weld is the primary determining factor, while, for bending pipe, the number of bends will control the amount of work expressed in manhours, that will be required.

In addition the actual stage of the construction cycle in which each of the work processes will be performed must be determined. Work done at a stage later than that at which it can be accomplished most efficiently will necessarily require more manhours to accomplish.

These data are entered into the appropriate rows and columns of the spreadsheet by an operator and the program calculates the required manhours. Based on the dollar cost per manhour that has been entered into the program the labor costs are also calculated. Material costs are calculated separately and added to the manhour costs to generate total cost.

Separate programs have been provided for work done by the structural piping, HVAC, and electrical trades. Within structures and piping, separate programs have been provided for different types of materials. The following programs are provided in the COST subdirectory

PIPICFE.WK1	- For Carbon Steel P1 Piping installations
PIPICRES.WK.1	- For CRES P1 Piping installations
PIPINICU.WK1	- For Copper-Nickel P1 Piping installations
PIP2CFE.WK1	- For Carbon Steel P2 Piping installations
PIP2CRES.WK 1	- For CRES P2 Piping installations
PIP2NICU.WK1	- For Copper-Nickel P2 Piping installations
STRCTMS.WK1	- For Mild Steel Structural work
STRTHY80.WK1	- For HY80 Steel Structural work
STRCTHTS.WK1	- For HTS Steel Structural work
STRCTAL.WKI	- For Aluminum Structural work

- | | |
|-----------|---------------------------------------|
| HVAC.WK1 | - For HVAC System installations |
| ELECT.WK1 | - For Electrical System installations |

The Appendix provides a copy of each of the above mentioned forms, and of the data used to generate the process factors.

DESCRIPTION

General - Each of the cost estimating computer programs is in a similar format. Most of the fields in the forms are protected, so that you cannot accidentally change them. The description that follows addresses only those fields into which you are expected to enter data. Figure 2-1 shows how the screen will appear for entering structural data into the mild steel structural form.

Project Title - Spaces are provided at the top of each form for inserting the name of the project and the new file name to be used for the specific design variant being evaluated. The project name of "TEST" and the file name of "STRUCTVAR" have been entered in the appropriate fields in Figure 2-1.

Material Parameters - In the next line or lines, fields are provided for entering the specific size or thickness or other controlling parameters of the material covered by the form. The same basic form may be used for several different sizes of the form's material but not in general for different materials. For example, the form for Mild Steel structure maybe used for material thicknesses from 1/4 inch to 2 inches, but a different form is needed for HY-80 materials. Similarly, the form for steel pipe can be used for piping diameters from 3/8" to 8" piping installations and for schedules 40, 80 or 120, but a different form is needed for CuNi piping.

In Figure 2-1, 0.5 inch has been entered into the material thickness field. After entering this value, press the F9 key to obtain the correct values to be used for the Work Factors. The computer program generates these values from a "Look-Up" table that is stored on the same spreadsheet form. The content of the lookup tables for each of the various forms are included with copies of the forms in the Appendix.

Data Entry - You or other Engineers or Cost Estimators, noting the work factors identified in the Work Factor column for each Work Process, need to evaluate the design and how it would be constructed, to determine the quantity of each of the controlling work factors involved in the design. For instance, you must know the number of pieces, the number of feet of weld, the number and type of pipe joints-or bends, the number of feet of electrical cable to be pulled, etc. Enter these values into the Unit Amount field opposite the process to which they pertain.

In Figure 2-1, the value of 100 has been entered into the Unit Amount column for the work process of Obtaining Materials, 20 feet of manual flame cutting is required, and 40 feet of flat grinding is required for edge preparation.

Work Stage - The various Work Stages considered in this project are listed below., along with the multiplying factor used in determining the effect of accomplishing work in later than the optimum stage for minimum manhours. These values also are contained in a lookup table on each spreadsheet form and the related multiplication factors are automatically applied when the Actual Stage is different than the Standard Stage.

<u>Work Stage</u>	<u>Definition</u>	<u>Multiplier</u>
1. Fabrication	In Shop	1.0
2. Preoutfitting Hot	On Platen - Hot Work	1.5
3. Paint	Paint Shop	2.0
4. Preoutfitting Cold	On Platen - Cold Work	4.0
5. Erection	Building Ways - On Block	5.0
6. Outfitting	Building Ways - Enclosed	7.0
7. Waterborne	Pierside after Launch	10.0
8. Tests and Trials	Pierside and Underway	15.0

When using these forms during early stage design efforts, it would be reasonable to assume that all of the work when done, will be accomplished at the ideal or standard work stage. In that case, no changes would be needed in the column headed "Actual Stage", since the form is prepared with the the two columns having identical values. For ships that are already in

Figure 2-1

construction, however, or for work to be done during an overhaul much of the work may have to be done on board, in poor working environments, instead of in the shop or wherever the 'work could be done most productively. In these cases, the stage at which the work will actually be accomplished must be entered into this column for each work process.

The value of 7, corresponding to the Waterborne work stage, has been entered into the Actual Stage column for the flame cutting process.

Manhours - When all of the data described above has been entered into the spreadsheet form the manhours required for each of the processes will be calculated in the rightmost column. In Figure 2-2, which is a printout of the entire spreadsheet form (which is too large to be seen on the computer screen at one time) 12 manhours are shown to be required for flame cutting, a value obtained by multiplying .090 manhours per foot by 20 feet times the work stage multiplier ratio 10.0/1.5.

Total Manhours - The total number of direct manhours will be indicated at the bottom of the Manhours column. The value of 394 manhours is shown in Figure 2-2.

Means has been provided for identifying a manhour multiplication factor, in order to account for the assist trade manhours. This is set at 35% in the tables provided and has been placed in a protected field but this can be "unprotected" and changed for any situation when that is considered appropriate. The sum of direct and assist trade manhours is then listed, as well. In Figure 2-2, the values 138 and 532 have been calculated for the assist manhours and total manhours, respectively.

Manhour Cost - To obtain the labor cost the total manhours are multiplied by a Dollars per Manhour figure. This figure also is in a protected field which can be changed easily to meet actual conditions. A value of \$20.00 has been used in the forms initially provided yielding a labor cost of \$10,639.

Material Cost - The material cost must be calculated separately. However, once determined, the value for material cost can be entered into the format at the bottom to generate the total cost for construction of the system that is being considered. The value of \$750 has been used for the material cost in Figure 2-2.

Total Cost - The total cost of the entire design will appear at the bottom of the screen when all of the data involved has been entered. Figure 2-2 shows the value of \$11,389.

SAVE

When all of the data has been entered and all of the calculations have been completed, SAVE the form using a unique file name that describes the evaluation that has been made.

REPORT

The information entered into and calculated by the program would normally be printed out in hard copy for review and recording the results. As previously indicated, Figure 2-2 is an example of the result of doing so.

COMPARATIVE ANALYSES

The same forms may be used for identifying the cost differences between two alternative designs, by entering, into each work process, the differences of work units between the two alternatives. Thus if Alternative 1 requires 85 feet less of flame cutting than another alternative, enter 85 feet and the result will be the manhour and cost savings to be achieved by selecting Alt 1 as the design to use. Likewise, if some aspect of one design alternative (or one production approach) allows more work to be done in the shop instead of being done on board, the effect of that work stage change can be directly calculated. Examples are provided in Reference 1.

Chapter 3- RELATIVE PRODUCIBILITY EVALUATION

GENERAL

This chapter describes the use of the two programs which are used to determine and record the relative producibility of various design alternatives. The programs are contained in the PROD directory of the floppy disk which accompanies this manual. One of the programs is written in GW-BASIC and stored in the subdirectory PROD\BASPROG, and the other is in spreadsheet format and stored in the PROD\SPRDPROG subdirectory.

The producibility criteria used in these programs are those which were determined during the research described in reference 1. The spreadsheet program described in this chapter also uses the producibility criteria weighting factors that were obtained during that research effort. Chapter 4 provides detailed instructions for operation of the computer programs used to determine those weighting factors and to reevaluate them when necessary.

PRELIMINARY

The first program to be used for evaluating the relative producibility of two or three design alternatives is the GW-BASIC program. If the GW-BASIC application program is not on your computer's hard disk it can be found on the main directory of the floppy disk provided with this manual. After selecting the directory or subdirectory where the GW-BASIC application program is located, enter GWBASIC. Where the "A" drive is indicated use "B" if appropriate.

Type LOAD" (or hit the F3 key) followed by A:\PROD\BASPROG\PRODC", and Enter. The initial screen of the program will then appear. Make sure your printer is on.

If it is necessary to exit from the program prematurely, enter Ctd + C. This will place you back into the GW-BASIC screen. To exit from GW-BASIC, enter SYSTEM.

INITIAL DATA INPUT

The first screen illustrated in Figure 3-1, asks for various data to be entered. Enter the name of the Project (normally the ship type or class designator, such as DDGX), and then the name of the design variant that is being evaluated. Next you will be asked to provide titles for each of up to three alternative designs for this variant that are to be evaluated for their relative producibility. If there are three alternatives, you will be asked to set a limit for the consistency ratio or to accept the default value of 0.2. For only two alternatives, the consistency of evaluations is always perfect giving a consistency ratio value of 0.0, so you will not be asked to select this value when only two alternatives are being considered.

Figure 3.1 illustrates what this screen looks like when all of the questions on it have been answered and before the Enter key is pressed after entering the desired consistency ratio value. The Project name, design variant descriptor and the names of the three alternatives chosen for this illustration are "TEST", "STRUCTVAR.", "NEW WAY", "LAST WAY" and "OLD WAY", respectively. The value of the consistency ratio has been changed to 0.25, primarily for purposes of illustration.

EVALUATOR INPUT

The screens that next appear record an individual evaluator's assessments of the relative producibility of the different design alternatives being considered. After entering the name and organization of the evaluator, you will be presented with a table which lists the 10 higher level producibility criteria which may be evaluated. This screen appears as shown in Figure 3.2.

```

Enter the Project or Ship Type Identifier      : TEST
Enter the design change being evaluated       : STRUCT VAR
Enter a TITLE for Alternative 1 (8 letters or less) : NEW WAY
Enter a TITLE for Alternative 2 (8 letters or less) : LAST WAY
Now name Alternative 3 (8 letters) or press ENTER to bypass : OLD WAY
The Alternatives you have chosen are listed below:
      Alternative 1 is      NEW WAY
      Alternative 2 is      LAST WAY
      Alternative 3 is      OLD WAY
Are these Alternatives Correct? (<Y>/N) :
The data to be entered will be rejected if the data is found to be
excessively inconsistent. The limit currently set for the
consistency factor is .2. To modify this limit, enter Y now.
Any other entry will leave the limit it at .2 : Y
Enter your choice for the consistency factor limit      : .25

```

Figure 3-1

After you select one of these, by entering a number between 1 and 10, the program lists all of the subcriteria used to evaluate that particular choice, as shown in Figure 3-3. You will then be led through all of the steps necessary to determine the weighting to be applied to each design alternative for any or all of those subcriteria. Once these comparisons have been completed, you can select another of the 10 criteria shown in Figure 3.2 and repeat the process for the subcriteria related to that choice.

As illustrated in Figure 3.3, after listing the subcriteria of the chosen criterion the program asks whether each, some or only of the subcriteria will be evaluated. For each subcriterion, you will be asked whether you will use hard data. Hard data is actual quantitative information such as the number of feet of welding the number of pipe bends, etc. When quantitative information is available, it should be used. In some cases of hard data such as feet of weld larger quantities lead to additional manhours, thus to lower producibility. In other cases, such as component packaging larger quantities yield higher producibility. Whenever hard data is to be entered, the program indicates whether higher values or lower values will be considered the more highly producible.

Figure 3-3 illustrates the results of entering 300,400 and 500 as the values for material cost. The opportunity to change values is always provided. After you have entered values with which you are satisfied, the program will display the weighted values for each of the design alternatives, as shown at the bottom of Figure 3.3.

If hard data is not available, the program will lead you through a series of comparisons of each of the design alternatives, asking which of the two is superior from a producibility standpoint with respect to the subcriterion being evaluated. Figure 3.4 illustrates the steps of this process.

Enter Name of Evaluator : A PERSON
 Enter Evaluator's Organization: A COMPANY

ENTER VALUE FOR LAST WAY : 400

ENTER VALUE FOR OLD WAY : 500

WANT TO CHANGE ANY OF THE VALUES? (Y,<N>) : N

JUDGMENTS ARE:

FOR: (1) MATERIAL COSTS

NEW WAY = 0.4255

LAST WAY = 0.3191

OLD WAY = 0.2553

Consistency Ratio = 0.0000

Lambda Max = 3.0000

TO CONTINUE, Press <Y>

Figure 3-3

The alternative "New Way" was considered to be the superior choice, so "1" was entered. The programmer next asks for the factor of superiority. The value 3 was entered indicating that "New Way" is considered three times as good as "Last Way" with respect to Wasteage Factor. The process continues, comparing each design alternative against each other design alternative.

```

FOR CRITERION (2) WASTEAGE FACTOR
WILL YOU USE HARD DATA? (Y, <N>) : N

IS ( 1 ) NEW WAY OR ( 2 ) LAST WAY SUPERIOR? :1
FACTOR OF SUPERIORITY? MUST BE 1 (EQUAL) OR GREATER :3
WANT TO CHANGE EITHER VALUE? (Y/<N>) :

IS(1) NEW WAY OR(3)OLD WAY SUPERIOR? :1
FACTOR OF SUPERIORITY? MUST BE 1 (EQUAL) OR GREATER :5
WANT TO CHANGE EITHER VALUE? (Y/<N>) :

IS(2) LAST WAY OR(3)OLD WAY SUPERIOR? :2
FACTOR OF SUPERIORITY? MUST BE 1 (EQUAL) OR GREATER :2
WANT TO CHANGE EITHER VALUE? (Y/<N>) :

ARE ALL THE ENTRIES CORRECT? (<Y>/N) :

JUDGEMENT ARE:
FOR: (2) WASTEAGE FACTOR
      NEW WAY= 0.6483
      LAST WAY = 0.2297
      OLD WAY= 0.1220
      Consistency RATIO = 0.0032
      Lambda Max= 3.0037

```

Figure 3-4

Following the entry of the data, the weighting factor for each of the design alternatives is calculated and printed out on the screen. Note that the consistency ratio for these entries was greater than zero, but less than 0.25, so the data was accepted. (The data is slightly inconsistent since, if (1) is three times as good as (2) and five times as good as (3), (2) should be 1.67 times as good as (3), rather than twice as good.) If the data is too inconsistent you will be given the opportunity to reevaluate the alternatives; otherwise the data will not be printed out.

After all of the producibility criteria for which the design alternatives are considered to have different relative values have been assessed by one evaluator, the data for another evaluator can be entered. When there are no more evaluations to be made, the program ends. Entering SYSTEM takes you out of the GW-BASIC application program and returns you to the screen from which you began.

PRINTED REPORTS

As you enter data and the computer carries out its calculations, information is sent to the printer buffer. Whenever a complete page of data is entered the printer will print out a page without any action on your part. At the end of the session when you indicate that there are no more evaluations to be made, the last page will be printed.

Figure 3.5 illustrates the format of the printed reports which the program generates. This figure documents the data entered in the screens pictured in Figures 3.1 through 3.4. Having all of the entered data recorded in addition to the final weighting factors, allows review of the data that was entered in order to resolve any apparent discrepancies in the resulting weighting factor values.

PRODUCIBILITY CRITERIA EVALUATION of Design Alternatives for TEST Program
 Design Variant: STRUCT VAR Consistency Ratio Limit = 0.2500

Evaluation by A PERSON of A COMPANY

MATERIAL (2) WASTEAGE FACTOR Weights	0.6483	0.2297	0.1220	0.0032

Figure 3-5

RESOLVING EVALUATOR DATA DIFFERENCES

Preferably, each design change should be evaluated by several knowledgeable persons, to obtain as broad an assessment as possible. Where the results of various evaluators are significantly different attempts should be made to resolve the differences before going further. Since each evaluator's choices are recorded on hard copy print outs, it is simple to identify where the evaluators' differences are. The program can be reused as often as desired for any reevaluations based on changes to evaluators' data. Since the data is not recorded in the computer's files, no problem is created by reentering additional, different data by or from any of the evaluators.

SPREADSHEETS

After the data from all of the evaluators has been obtained an average weighting factor for each design alternative must be calculated for each subcriterion that was evaluated. This is done using the spreadsheet program

After going into your spreadsheet application program load the file

A:\PROD\SPRDPROG\WATEFORM.XXX,

where the "A" should be replaced by whatever drive the floppy is actually in and the ".xxx" must be replaced with the file extension that applies to your application program; ".WK1" for LOTUS 123, for instance. Figure 3.6 shows how the initial screen will appear after some initial information has been entered.. Many of the fields of the spreadsheet are "protected", since there is no need to enter any data in those fields. Protected fields are indicated on the actual screens by color coding

Enter the name of the project and that of the design variant in their respective fields. Then enter the number of evaluators. The form provided allows for the data for up to six evaluators. If the alternatives are compared by more than six evaluators, the form will have to be modified by adding additional columns.

Figure 3-6

Enter the name of the first evaluator in the space identified as "Evaluator #1" Three columns are provided for the data from each evaluator, one column for each of the up-to three alternatives being compared. Enter the title for each of the design variant alternatives in the cells at the head of the three columns under the first evaluator. Important: If there are only two alternatives being considered the field for the third one must be filled as a blank The titles of the design variant alternatives need only be entered once. The computer program will automatically use the same titles in the appropriate columns of the rest of the form

When the titles of the alternatives have been entered enter the command to carry out calculation (F9 for LOTUS 123) The rows for each criterion will be automatically filled with the appropriate values for equally weighting each alternative. Thus, if there are three alternatives named the relative weight for each of them will appear initially as .3333, while if there are only two, the relative weights will be .5000 for alternatives 1 and 2 and .0000 for alternative 3.

These values will appear in the respective columns for only as many evaluators as were indicated in the number-of evaluators field. That is, if you have entered the number 2 as the number of evaluators, all fields in the columns for evaluators 3 through 6 will remain as zero. Notice in Figure 3-6 that the values in the last column to the right are all zero. This is the first column for the second evaluator. Since the number of evaluator has been indicated as 1, only the columns for evaluator #1 have been filled in with non-zero values.

Proceed to enter the weighting values for each evaluator from the printout obtained from the GW-BASIC pro-Figure 3-5. It will only be necessary to enter data for those criteria in which the alternative designs have differing weighting factors. Further, if there are just two alternatives, the values for only one of the alternatives will need to be entered since the other value will be calculated automatically, their sum having to equal unity. Similarly, in the case of three alternatives, only two of the three values need be entered for any criterion. In fact the third column of each evaluator is protected to preclude incorrect values from being entered.

Figure 3-7

If there are more evaluators than one, then, after the data from the first evaluator is entered, shift over to the columns for the second evaluator and enter those data. Continue until the data from all evaluators have been entered. Then again initiate calculation. The program will calculate the average values of all the evaluators' data, which will appear in columns AS, AU and AW, as shown in Figure 3-7. Since only one evaluator was used in this example, the values shown in Figure 3-7 are, of course, the same as those for evaluator #1 in Figure 3-6.

The criteria weighting values are shown in column AY. These values already will have been determined and entered into the spreadsheet form as described in the following Chapter.

If you then move the cursor to the right until columns AY through BE are visible on the screen the information shown in Figure 3-8 will be displayed. Columns BL BC and BE contain the product of the values in column AY and the values in columns AS, AU and AW, respectively, shown in Figure 3-7.

After all of the data has been entered and the Recalculate keys pressed move the cursor so that the values in fields BA80 through BE82 can be seen. These fields, illustrated in Figure 3.9, give the final overall weighted relative producibility factors. The alternative with the largest value in fields BA81 to BE81 will be the most producible alternative. However, as explained in Reference 1, these values are relative only in the qualitative sense, so that the largest value merely identifies the most producible design alternative. The values DO NOT indicate the quantitative relative cost of the alternatives.

Save the filled in worksheet to a file with a title other than WATEFORM so that the WATEFORM file will always be available for evaluating other design variants.

Print out the results for fixture reference and exit from the program.

Chapter 4 - DETERMINING PRODUCIBILITY CRITERIA WEIGHTING FACTORS

GENERAL

The producibility subcriteria weighting factors that were used to multiply each of the design alternative weighting factors in the spreadsheet described in Chapter 3, and shown in the center column of figures in Figure 3-7, are determined by pairwise comparisons using the AHP technique. The values of these producibility weighting factors need be determined only once for each project, since they are dependent primarily on the construction process rather than the mission of the ship. Once determined, they are entered into the spreadsheet WATEFORM and used for the producibility analysis of the alternatives for each design variant studied.

It is also not likely that these values will change significantly for different types of ship. However, should it be found necessary or desirable to do so, the programs described in this chapter would be used to determine new values.

The two programs for determining these factors are written in GW-BASIC, and are run using the GW-BASIC application program. The first of these programs, PRODA is used for recording the evaluations of individuals who are knowledgeable of the relative importance of the various producibility evaluation criteria to be used. The evaluations of the individuals may be obtained through the use of questionnaires and the results recorded in this program by an operator or they may be determined through an individual's direct use of the computer program. Each evaluator's responses are printed out as the program proceeds, providing a permanent record that may be studied separately.

The second program, PRODB, is used to obtain the normalized geometric mean of the values obtained from all of the individuals. This program is more likely to be run by a single operator once, after all the individual responses have been obtained. Again a printed report is generated as this program is run showing each individual's responses for a given criterion and the mean of all of the responses for that criterion.

The line item statements for each of these programs are listed in the Appendix.

RECORDING INDIVIDUAL EVALUATIONS

The first program is in the file named PRODA in subdirectory BASPROG in the PROD directory. After starting the GW-BASIC program at the start-up screen enter (using B: instead of A if appropriate)

```
LOAD"A:\PROD\BASPROG\PRODA",R
```

The initial screen for this program asks for the name of the project, the value to be used for the consistency ratio, the evaluator's name and organization. See Figure 4-1.

The next screen shown in Figure 4-2, lists all of the levels of the criteria/subcriteria tree. At the bottom of the screen, enter the number, listed under the title "Code", of the criteria which you will evaluate. In Figure 4-2, the number 3, corresponding to the criterion "SIMPLICITY", has been entered.

Enter the Project or Ship Type Identifier : TEST

The data to be entered will be rejected if the data is found to be excessively inconsistent. The limit currently set for the consistency factor is .2 . To modify this limit, enter Y now. Any other entry will leave the limit at .2 : Y

Enter your choice for the consistency factor limit : .25

Enter Evaluator's Name : A PERSON

Enter Evaluator's Organization: A COMPANY

Figure 4-1

***** Enter Criterion Code from List *****

Code	Label	Number of Sub-Criteria

Enter Criterion Code to be Evaluated: 3

Figure 4-2

Here are the SIMPLICITY SubCriteria:

- (1) SHAPE OF PIECES
- (2) ACCESSIBILITY
- (3) NUMBER OF PIECES

FOR COMPARISON OF
 (1) SHAPE OF PIECES WITH (2) ACCESSIBILITY
 WHICH HAS GREATER EFFECT ON MINIMIZING MANHOURS/COST? (1 OR 2) : 2
 BY WHAT FACTOR? Must Be 1 (Equal) or Greater. 3
 WANT TO CHANGE EITHER VALUE? (Y/<N>): N

FOR COMPARISON OF
 (1) SHAPE OF PIECES WITH (3) NUMBER OF PIECES
 WHICH HAS GREATER EFFECT ON MINIMIZING MANHOURS/COST? (1 OR 3) :
 BY WHAT FACTOR? Must Be 1 (Equal) or Greater. 2
 WANT TO CHANGE EITHER VALUE? (Y/<N>):

FOR COMPARISON OF
 (2) ACCESSIBILITY WITH (3) NUMBER OF PIECES
 WHICH HAS GREATER EFFECT ON MINIMIZING MANHOURS/COST? (2 OR 3) : 2
 BY WHAT FACTOR? Must Be 1 (Equal) or Greater. 5
 WANT TO CHANGE EITHER VALUE? (Y/<N>):

ARE ALL THE ENTRIES CORRECT? (<Y>/N):

Figure 4-3

Upon entering the choice of Code, you will be presented with another screen, which first identifies the subcriteria that must be reevaluated, as shown in Figure 4-3, and asks for an evaluation of the first pair of those. The program leads you through the evaluation of each pair of the subcriteria. As each question is answered, another question is asked or an opportunity for verification is given. The program leads you through the steps necessary to identify which one, of each pair of subcriteria, is considered to have the greater influence in minimizing construction man-hours/cost and then to identify the factor by which that subcriterion is superior to the other.

A superiority factor of 1 indicates that the two elements are equal from a producibility standpoint, whereas a factor of 2 indicates that the superior element is twice as good as the other.

After all of the subcriteria of the selected Criterion Code have been compared with each of the others, the program computes a consistency ratio, as shown in Figure 4-4. When only two subcriteria are involved, the value of this ratio will always be zero. However, when more than two are compared, the ratio probably will be other than zero. For instance, in the case of the data presented in Figure 4-3, the consistency ratio is greater than zero. This is because the superiority factor of (2) Accessibility, compared to (3) Number of Pieces, should be 6 (instead of 5) in order to be perfectly consistent with the factors used in the two preceding comparisons.

If the value of the ratio is acceptable, i.e., is less than the level identified at the start of the program, the data will be recorded in a file in the A:\PROD\DATA subdirectory. Otherwise you will be given the option either to enter revised data for the same subcriteria until the data consistency is adequate or to start again on another set of subcriteria.

```

FOR COMPARISON OF
(2) ACCESSIBILITY WITH (3) NUMBER OF PIECES
WHICH HAS GREATER EFFECT ON MINIMIZING MANHOURS/COST? ( 2 OR 3 ) : 2
BY WHAT FACTOR? Must Be 1 (Equal) or Greater.
WANT TO CHANGE EITHER VALUE? (Y/<N>): N
ARE ALL THE ENTRIES CORRECT? (<Y>/N): Y
JUDGEMNTS ARE:
For SIMPLICITY Subciteria:
(1) SHAPE OF PIECES = 0.2297
(2) ACCESSIBILITY = 0.6483
(3) NUMBER OF PIECES = 0.1220
consistency Ratio = 0.0032
LambdaMax= 3.0037

Producing Data File
Another Evaluation for the Same Person? (<Y>/N): N
Start a new person? (<Y>/N): N
Now exiting this program and closing the output data file.
OK

```

Figure 4-4

The results of each evaluation are presented on the screen, as indicated in Figure 4-4. Data will be sent to the printer buffer as it is entered and calculated. A hard copy will be printed as a full sheet is filled or upon completion of data entry. Figure 4-5 illustrates the format of the printed reports.

After entering each set of responses you will be asked whether you want to enter data for another set of subcriteria. The default response is yes and this response will cause Figure 4.2 to reappear. A negative response will allow you to choose to enter data for another evaluator or to quit the program. In Figure 4-4, both questions have been answered "No", in response to which the program will generate the printout of Figure 4-5 and end processing.

COMBINED WEIGHTING FACTORS

After all of the data from each of the individual evaluators has been entered into PRODA the mean values for each of the criteria levels can be determined through the use of PRODB. Enter

```
LOAD" A:\PROD\BASPROG\PRODB",R
```

After entering the name of the project, you will be presented with the list of criteria, Figure 4-6, which is the same as shown in Figure 4-2 except for the instruction at the bottom of the screen.

To obtain the weighting factors for a single level of the criteria tree, enter the number of the criterion of interest. To obtain the values for all of the levels of the project's criteria tree, enter 99 as the Code.

PRODUCIBILITY CRITERIA Weighting Evaluation for TEST Project
Consistency Ratio Limit = 0.2500

Evaluation by A PERSON of A COMPANY

For SIMPLICITY Subcriteria Weights,

There were 5 Evaluators. The Geometric Means of their responses are:

(1) SHAPE OF PIECES	Value =	0.2013
(2) ACCESSIBILITY	Value =	0.4512
(3) NUMBER OF PIECES	Value =	0.3475

The Geometric Mean of Lambda Max Total = 3.0230

Evaluate more Criteria for the same Project? (<Y>/N): N
Want To Evaluate Criteria for another Project? (Y/<N>): N
Ok

Figure 4-7

Figure 4-7 illustrates the result of having entered the value 3, to obtain the SIMPLICITY subcriteria weighting factors. The screen shows the number of evaluators for the selected criterion in addition to the final normalized geometric mean values of those evaluators' data.

When the value of 99 is entered, the screen will not show any results except a message that the values are being printed.

A printout will be provided, showing the names of each evaluator and their input data as well as the mean values, as shown in Figure 4-8.

When you have finished, enter SYSTEM to leave GW-BASIC.

PREPARING WATEFORM

The next step is to enter the weighting factors for each of the subcriteria, as generated from the PRODB program into the appropriate columns of the spreadsheet WATEFORM.XXX found in the PROD\SPRDPROG subdirectory. The rightmost columns of this form contain the formulas necessary to calculate the final values that ultimately are applied to the individual design alternative weighting values. These columns must be "unprotected" before new values can be entered into the cells. Figure 4-9 is a printout of the values that are provided in the form located on the disk provided with the manual. These values were determined by using the steps described in this chapter during the project described in Reference 1. A more complete description of the development and application of these values can be found in that document.

PRODUCIBILITY CRITERIA Weighting Factors for the TEST Project

Individuals' Weights for: SIMPLICITY SubCriteria are:

SOMEONE of COMPANY A	WEIGHT
(1) SHAPE OF PIECES	0.1684
(2) ACCESSIBILITY	0.4639
(3) NUMBER OF PIECES	0.3677
Consistency Ratio =	0.0891
Lambda Max =	3.1034

SOMEONEELSE of COMPANY B	WEIGHT
(1) SHAPE OF PIECES	0.1634
(2) ACCESSIBILITY	0.2970
(3) NUMBER OF PIECES	0.5396

Chapter 5 - DECISION MAKING AHP PROGRAMS

GENERAL

These programs are identical in concept to those used for evaluating the producibility of various design alternatives, except that producibility is only one of the criteria used for making the ultimate choice of which alternative is the best overall choice to be used in the design.

DECA, DECB and DECC are three programs written for GWBASIC, having the identical function and many virtually identical screens as PRODA, PRODB and PRODC, respectively. The primary difference is in the tree of criteria that is evaluated.

A significant consideration% however, is that the weighting factors for the elements of the decision making tree will vary considerably for different ship classes, rather than being essentially the same as in the case of producibility criteria weighting factors. They may in fact vary for different design stages of a single ship class. Thus, DECA and DECB will need to be run for each design stage of each project, with the results from DECB installed in the WATEFORM spreadsheet that is finally used to compare the various alternatives of each design variant studied in that design stage.

All of these programs are installed in the directory DEC. The BASIC programs are installed in subdirectory DEC\BASPROG, data from DECA is stored in DEC\DATA and the spreadsheet program used to average the information from each evaluator's use of DECC is WATEFORM stored in DEC\SRPRDPROG.

The BASIC statements used in DECA DECB and DECC are listed in the Appendix.

DECISION MAKING

Programs DECA and DECB need be accomplished only once for each ship type and design stage. They are the preliminaries to actually using program DECC for comparing the relative merits of with respect to any or all of the decision making subcriteria.

The process for using DECC is identical to that described in Chapter 3 for using PRODC.

The output from DECC is then entered into the spreadsheet WATEFORM found in the DEC\SRPRDPROG subdirectory. The results will be found at the bottom of columns BE to BG, in the same way as shown in Figure 3-7 for the Producibility Evaluation..
