14. ABSTRACT We hypothesize that targeted molecular intervention can preserve vision threatened by battlefield trauma-induced corneal and retinal inflammation, corneal and retina/optic nerve apoptosis, ocular surface dry eye after refractive surgery, and retinal degeneration. We are studying the consequences of trauma-induced (1) corneal inflammation using a gene therapy approach of providing soluble Fas ligand to the cornea to determine if this ligand can suppress corneal inflammation in mice; (2) retinal inflammation by examining if transforming growth factor-beta, thrombospondin, and somatostatin, in subretinal space, can suppress inflammation within retina secondary to autoimmune uveoretinitis and light-induced damage in mice; (3) corneal cell death by apoptosis and promote regeneration by identifying the anti-apoptotic gene with the greatest capacity to suppress corneal cell apoptosis using mice; (4) retinal cell death and regeneration by using mice to determine if systemic treatment with lithium chloride can prevent collateral damage to retinal neurons and promote optic nerve regeneration; (5) dry eye by determining how to minimize dry eye after LASIK refractive surgery by developing new tests to predict pre-disposition to refractive surgery induced dry eye; and (6) retinal injury by generating stem cell polymer composites.

DOD FY03 Interim Report Task #5
May 16, 2007

Introduction

An increasing percentage of battlefield injuries occur to the eye in modern warfare. Even treatable battlefield injuries to the eye can lead to blindness because of collateral damage to adjacent tissues. This blindness results from injury-induced inflammation, cell death, failure to regenerate and repair, and development of scar tissue. Task #5 is one portion of a multidisciplinary project that addressed corneal blindness resulting from abrasions, burns, and penetrating wounds acting on normal corneas or exaggerated in corneas that have undergone refractive surgery, as well as retinal blindness resulting from physical trauma, infection, or laser-induced injury that destroy retinal nerve cells. In task 5 our goal is to prevent the consequences of trauma to the cornea after refractive surgery by developing strategies to diagnose dry eye syndromes. Our specific objective was to determine if there are individuals in whom the goblet cells of the conjunctiva do not respond normally to neural and growth factor stimulation and if this abnormal response predisposes these individuals to developing chronic dry eye after laser refractive surgery. Our three subtasks were to 1: determine if the response of conjunctival goblet cells to nerves and growth factors is reduced in a mouse model of dry eye and if loss of corneal nerves (induced by a corneal wound) alters this response. The loss of corneal nerves by a corneal wound mimics the loss of nerves induced in laser refractive surgery. 2: determine if human goblet cells from normal human controls respond to the growth factor EGF, the β -adrenergic agonist isoproterenol, and the cholinergic agonist carbachol. 3: Determine if patients with reduced goblet cell response will have an increased rate of dry eye symptoms and traumatic complications after laser refractive surgery.

Body

I. Research accomplishments for subtask 1: We have finished our studies on measuring alterations in phosphoprotein levels in conjunctiva of Balb-c mice following stimulation with EGF, carbachol and isoproterenol. We performed corneal wounding (superficial keratectomy) in 12 week-old Balb-c mice in order to mimic laser refractive surgery. Corneal wounding was done in the right eye and left eye was kept unwounded. Mice not wounded in either eye were considered as the controls. The conjunctiva was isolated from both eyes at different time points (2 days, 6 days, 2 weeks and 4 weeks) following wounding and divided into four pieces. Long time points were chosen as our goal is to study chronic dry eye that develops after surgery in a percentage of individuals rather than the acute dry eye that occurs in almost everyone after this surgery. Conjunctival tissue pieces were stimulated with no additions (basal), EGF (10^{-7} M), carbachol (10^{-5} M), and isoproterenol (10^{-5} M) for 5 minutes at 37° C in a water bath. The reaction was stopped in keratinocyte basal medium kept at 4° C. The conjunctival lysates were prepared by homogenizing the tissue in RIPA buffer. BioRad multiplex assay was done to study the levels of various phosphoproteins in the conjunctival lysate samples and to determine alterations in the phosphoprotein levels following corneal wounding. Seven-plex assay kit was used to measure the levels of phosphorylated ERK (p42/p44 mitogen-activated protein kinase), JNK, p38 mitogen activated protein kinase, AKT, I κ B alpha, STAT-3 and P70S6 at the same time in each sample. Phosphoproteins levels were standardized to the amount of total ERK (phosphorylated and non-phosphorylated) in each sample. The data were analyzed using Bioplex manager software and fold increase in phosphoprotein levels was determined over the basal levels. Statistical analysis was done using student T test and P <0.05 was considered as significant.

A. Results from non-wounded control mice:

Table 1 summarizes the results from 12 week-old control (n=7) mice. We found:

1. Significant increase in phosphorylated ERK following stimulation with EGF and carbachol.
2. Significant increase in phosphorylated AKT following stimulation with EGF and carbachol.

3. Significant increase in STAT-3 following stimulation with isoproterenol.
4. Decrease in the levels of P70S6 were seen following stimulation with isoproterenol, although it was not statistically significant.

B. Results from the wounded (right) eye 2 days following corneal wounding :

Table 2 summarizes the results in the wounded eye 2 days after superficial keratectomy performed in 12 weeks old Balb-c mice (n=5). We found:

1. Significant increase in phosphorylated ERK following stimulation with EGF and carbachol.
2. Significant increase in phosphorylated JNK following stimulation with EGF and carbachol.
3. Significant increase in phosphorylated P38 MAPK following stimulation with EGF.

C. Results from the unwounded (left) eye 2 days following corneal wounding :

Table 3 summarizes the results in the unwounded eye 2 days after superficial keratectomy performed in 12 weeks old Balb-c mice (n=5). We found:

1. Significant increase in levels of phosphorylated ERK following stimulation with EGF.
2. Significant increase in phosphorylated JNK following stimulation with carbachol.
3. Significant increase in phosphorylated P38 MAPK following stimulation with EGF and carbachol.
4. Significant increase in phosphorylated AKT following stimulation with isoproterenol.
5. Significant increase in phosphorylated I κ B alpha, STAT-3 and P70S6 following stimulation with carbachol.

D. Results from the wounded (right) eye 6 days following corneal wounding

Table 4 summarizes the results in the wounded eye 6 days after superficial keratectomy performed in 12-week old Balb-c mice (n=3). We found:

1. Significant decrease in phosphorylated p38MAPK following stimulation with EGF.
2. Significant decrease in phosphorylated AKT following stimulation with EGF.

E. Results from the unwounded (right) eye 6 days following corneal wounding

Table 5 summarizes the results in the wounded eye 6 days after superficial keratectomy performed in 12-week old Balb-c mice (n=3). We found:

1. Significant increase in phosphorylated pERK following stimulation with EGF and carbachol.

F. Results from the wounded (right) eye 2 weeks following corneal wounding

Table 6 summarizes the results in the wounded eye 2 weeks after superficial keratectomy performed in 12-week old Balb-c mice (n=6). We found:

1. Significant increase in phosphorylated pERK following stimulation with EGF.
2. Significant increase in phosphorylated pJNK following stimulation with EGF.
2. Significant increase in phosphorylated pAKT following stimulation with carbachol.

G. Results from the unwounded (right) eye 2 weeks following corneal wounding

Table 7 summarizes the results in the unwounded eye 6 days after superficial keratectomy performed in 12-week old Balb-c mice (n=6). We found:

1. Significant decrease in phosphorylated p38MAPK following stimulation with carbachol.

H. Results from the wounded (right) eye 4 weeks following corneal wounding

Table 8 summarizes the results in the wounded eye 4 weeks after superficial keratectomy performed in 12-week old Balb-c mice (n=6). We found:

1. Significant increase in phosphorylated pERK following stimulation with EGF.

I. Results from the unwounded (left) eye 4 weeks following corneal wounding

Table 9 summarizes the results in the unwounded eye 4 weeks after superficial keratectomy performed in 12-week old Balb-c mice (n=6). We found:

1. Significant increase in phosphorylated pERK following stimulation with EGF.

J. Summary of completed experiments

Table 10 summarizes the number of completed experiments

We have done:

1. Seven stimulation experiments on unwounded mice and analyzed all seven with multiplex.
2. Five stimulation experiments on mice 2 days after wounding and analyzed all five with multiplex.
3. Four stimulation experiments on mice 6 days after wounding and analyzed three with multiplex. Samples from one mouse were unable to be analyzed.
4. Six stimulation experiments on mice 2 weeks after wounding and analyzed six with multiplex.
5. Six stimulation experiments on mice 4 weeks after wounding and analyzed six with multiplex.

K. Future experiments for subtask 1

Experiments for subtask 1 are completed, but we will perform additional statistical analysis to determine if there are differences in the response of phosphoproteins between control and wounded eyes with time and between unwounded and wounded eyes at each time point. With the completion of this statistical analysis we will be able to conclude whether or not corneal wounding cutting the corneal nerves causes chronic changes in the responsiveness of the conjunctiva to neurotransmitters and growth factors.

II. Research Accomplishments for Subtask 2: As Dr. Dimitri Azar our initial collaborator moved from Massachusetts Eye and Ear Infirmary, we revised our IRB protocol to remove him as the doctor to whom adverse events would be reported and replaced him with Dr. Reza Dana. Impression cytology samples were removed from ___ volunteers. Four samples were obtained from one eye. In the first patients we developed the method for collecting cells from the nitrocellulose membrane and found that placing the membrane in a glass centrifuge tube and centrifuging resulted in the best yield of cells and the most responsive cells as determined by western blotting analysis. Unfortunately not enough protein was recovered in each sample to perform the multiplex analysis. We thus decided to combine samples resulting in two final samples. These samples will be stimulated by no additions and carbachol. Unfortunately we will not be able to study the effect of EGF and isoproterenol. This is all right as carbachol works via EGF and isoproterenol did not stimulate any phosphoprotein activity in the mouse model. We will next collect samples from a small number of subjects, combine the cells, and analyze by multiplex. If this is successful we will be able to start subtask 3.

III. Research Accomplishments for Subtask 3: As Dr. Dimitri Azar our initial collaborator moved from Massachusetts Eye and Ear Infirmary, we enlisted COL Kraig S. Bower and LTC Charles Coe from Walter Reed Army Medical Center as new collaborators. Our IRB documents have been approved and I have met with these individuals to plan the details of the clinical study. The study will commence as soon as the final results from specific aim 2 have been obtained.

KEY RESEARCH ACCOMPLISHMENTS

- Developed a method for measuring multiple second messengers in a single conjunctival sample using bioplex technology.
- EGF and cholinergic agonists cause changes in phosphoproteins ERK and AKT in control, unwounded, mouse conjunctiva, but β -adrenergic agonists alter STAT-3 and perhaps P79S6.

- Two days after wounding the wounded and unwounded conjunctiva respond differently from each other and differently from the control unwounded mice.
- Six days after wounding conjunctival response is lost.
- Two and four weeks after wounding, conjunctival response begins to return.
- Conjunctival cells responsive to carbachol can be collected by impression cytology from human subjects.

•

REPORTABLE OUTCOMES

Konomi K., Azar D., Dartt D.A. Alteration in Signaling Pathways in Mouse Conjunctiva after Corneal Wounding Mimicking Nerve Loss in LASIK Surgery, Invest. Ophthalmol. Vis. Sci. 2006 47: E-Abstract 4600.

CONCLUSIONS

We conclude that in the normal mouse conjunctiva, the epithelial cells differentially respond to growth factors, cholinergic and beta-adrenergic agonists. Corneal wounding that mimics laser refractive surgery changes this response. Human conjunctival cells can be collected by impression cytology for studying conjunctival function.
