John L. Atkins, Research Analyst

E.R.D.E.

N. W. Luft is the author of Explosives Research and Development Establishment Tech. Memo No. 2/M/50. The Thermodynamic functions - $(F^0 - H_8)/T$, S^0 , C_p^0 , $\log K_f^0$ in the temperature range from 300 to 2000°K. are given for the following molecules: - F, F₂, HF, ClF, BrF, IF, BoF, F₂O,

NF₃, PF₃, AsF₃, ClF₃, BF₃.

SiF₄, SF₆.

CF₄, COF₂, C₂F₆.

A series of important equilibrium constants have been calculated.

COMMENT: Fluorine and its derivatives will be of interest to the Rocket and Jet Propulsion Sections of Ordnance Department. The U.S. Naval and Air Attaches, London, have received 5 copies each of this publication. One copy for S&D Board.

Dist. by Orig.: 1 cy to ORDTU; 1 cy to Picatinny Arsenal

I. SUMMARY.

The thermodynamic functions - $(F^0 - H_0^0)/T$, S^0 , C_p^0 , $\log K_f^0$ in the temperature range from 300 to 2000°K. are given for the following molecules:-

F, F₂, HF, ClF, BrF, BF, BeF, F₂O,

NF₃, PF₃, AsF₃, ClF₃, BF₃,

SiF₄, SF₆,

CF₄, COF₂, C₂F₆.

A series of important equilibrium constants have been calculated.

II. NOTATION.

r_0 = nuclear separation, bond length (in the zero vibrational level), ($A = 10^{-8}$ cm.).

B = rotational constant (cm^{-1}).

I = moment of inertia (10^{40} g.cm²).

ω = vibrational frequency (cm^{-1}). In polyatomic molecules the degeneracy is added in brackets.

$x\omega$ = anharmonicity constant (cm^{-1}).

v = vibrational quantum number.

ν = value of electronic term (cm^{-1}).

s = symmetry number.

M = molecular weight.

P_E = statistical weight of electronic state.

μ = dipole moment (Debye Unit = 10^{-18} e.s.u.).

P = (partial) pressure (atm.).

$(F) \equiv -(F^0 - H_0^0)/T$ = free energy function.

S^0 = (virtual) entropy, not containing contributions from nuclear spin (S_N) and isotope mixing (S_{mix}).

C_p^0 = molar heat capacity.

RESTRICTED

RESTRICTED

ΔH = enthalpy of reaction.

ΔH_f° = enthalpy of formation from elements in their standard states.

D = dissociation energy.

K_p = equilibrium constant.

K_f = equilibrium constant of formation.

R = universal gas constant.

T = temperature ($^\circ K.$).

III. INTRODUCTION.

Recently the chemistry of fluorine compounds has become the object of increased interest (1,2,3), mainly because of the possible technical applications of such compounds. The thermodynamic functions of certain fluorine compounds have therefore been calculated and from these, equilibrium data for various reactions of technical interest have been obtained.

Some of these data are taken from the literature. Additional data have been calculated from spectroscopic results by well-known statistical methods (4,5,49).

As the main interest lies in the region below 2000 or even 1500 $^\circ K.$ it has been thought sufficient to use the model of the harmonic oscillator and rigid rotator ('HRR-approximation') in these calculations for molecules in the perfect gas state. Vibrational contributions were calculated from Wilson's tables (cf.4).

IV. SPECTROSCOPIC, MOLECULAR AND THERMOCHEMICAL DATA.

The practical limit to the accuracy of the calculated figures is set by the accuracy of available spectroscopic, molecular and thermochemical data. These data are reviewed in the following sections; thus an estimate of the accuracy of the thermodynamic functions in the appendix is easily possible.

1. Atomic fluorine, F.

Apart from the ground state $^2P_{3/2}$ with $p_{EO} = 4$, the first excited state $^2P_{1/2}$ at $\nu_{E1} = 407 \text{ cm}^{-1}$ is also taken into account. The $^4P_{5/2}$ state has no influence below $T = 4000^\circ K.$

Murphy and Vance (7) represent the free energy function of atomic fluorine by the formula:-

RESTRICTED

$$-(F^{\circ} - H^{\circ}_O)/T = a/T + b \log T + cT + dT^2 + i$$

with $a = -754.75$, $b = 4.6445$, $c = 40.38 \times 10^{-4}$, $d = -74.70 \times 10^{-8}$

$$i = 22.5832.$$

This formula gives satisfactory results up to about 2000°K. which agree closely with the figures of Table I. The contribution $S_N = 1.377$ for nuclear spin $\frac{1}{2}$ is not included in these figures.

Equilibrium constants of formation of atomic fluorine according to the equation

have been calculated with the enthalpies of formation $\Delta H^{\circ}_O(F) = +20$ and $+16.2$ k.cals. (see below).

2. Fluorine, F_2 .

The ground state is Σ_g^- , point group $D_{\infty h}$ $P_{EO} = 1$, $s = 2$. Electron diffraction measurements (8) give the nuclear equilibrium distance $r_e(F-F) = 1.435 \pm 0.01$; from this, $r_0 = 1.45$ is assumed; this gives a moment of inertia of $I_0 = 33.16$ in fair agreement with (7).

Apart from less reliable data e.g. Born-Haber cycles for the lattice energy of fluorides according to Meyer-Helmholtz, there has been recent experimental evidence (9) for a low value of the dissociation energy of F_2 viz:-

$$D(F_2) \equiv 2\Delta H^{\circ}_O(F) = +32.4 \text{ k.cals.}$$

from a spectroscopic determination of $D(FCl)$ and a value of $\Delta H^{\circ}(FCl) = -15.0$ k.cals. A second new value $\Delta H^{\circ}(FCl) = -11.6$ k.cals. (ref.20) gives $D_0(F_2) = +39.5$ k.cals.

A low value of this order is supported by various thermochemical arguments, cf. (6), (26). Equilibrium constants K_f° for the formation of atomic fluorine F are given in the appendix with the two values $\Delta H^{\circ}_O(F) = 16.2$ and ~ 20 k.cals., since the previous value $D(F_2) \sim 63$ k.cals. is not supported by direct measurement.

The vibrational frequency of F_2 in the ground state is not known for certain. Together with unknown upper states it may be the main source of error. Gale and Monk (10), who could not detect a limit of convergence in absorption as far as $\lambda 4100\text{\AA}$ (~ 69 k.cals.), made an analysis of F_2 bands between $\lambda 5100\text{\AA}$ and $\lambda 7200\text{\AA}$ in emission. Structure and intensities indicate a ${}^1\Sigma - \Pi$ transition with

$$\nu = 17438.8 + (1104.9\nu' - 2.9\nu'^2) - (1071.5\nu'' - 9.9\nu''^2)$$

$$I'_0 = 34.2; \quad r'_0 = 1.48; \quad I''_0 = 26.0; \quad r''_0 = 1.28$$

/Although

RESTRICTED

Although this system probably involves only upper states and shows perturbation, both vibrational frequencies have been wrongly used at times for the ground state of F_2 (cf. 11).

Murphy and Vance (7) derived an approximate value of ω_0 by means of Badger's rule (12). With the old value $r_e = 1.45$ they obtain $\omega_0 = 856 \text{ cm}^{-1}$, whereas the new $r_e = 1.435$ gives $\omega_0 = 892$ and 1062 cm^{-1} from the rules for rows and columns of the periodic table respectively (cf. 8). From a comparison of the vibrational frequencies for I_2 , Br_2 , Cl_2 (cf. 14, 15) in the ground state $^1\Sigma^+$ and 8 stable upper states:-

$$^3\Pi_u; ^3\Pi_{og}; ^3\Pi_u; ^3\Sigma_u^+; ^3\Pi_g; ^1\Sigma_u^+; \Pi_{21g}; ^1\Pi_g$$

one finds that Π_{21g} is the only upper state in which ω_0 is greater than in the ground state, and $r_e^n (\sim 1/\omega_0)$ smaller. If this is also true for F_2 then Gale and Monk's spectroscopic results indicate that in the ground state of F_2 the vibrational frequency is not smaller than $\omega \sim 1070 \text{ cm}^{-1}$.

Owing to the lack of data this frequency $\omega_0 = 1070$, supported by the above result from Badger's rule, is used in the following calculations.[‡] $\omega \sim 1130$ quoted in (11) would cause only a minor difference.

From any of these values of ω_0 and the low value of $D(F_2)$ a high anharmonicity $x_e \omega_0$ must be expected; this is in agreement with an argument by Walsh (13) on possible repulsion between bonding and other orbitals in molecules made up of small and highly electro-negative atoms. An approximate value for $x_e \omega_0$ can be derived by applying the rule (14).

$$m^{\frac{1}{2}} x_e \omega_e r_e^n = \text{const.} \quad m^{\frac{1}{2}} = \text{reduced mass}$$

in the series of halogens, viz. $x_e \omega_e \sim 20 \text{ cm}^{-1}$. Linear extrapolation of vibrational levels to their convergence limit (45):-

$$D_0 = \frac{\omega_e^2}{4 x_e \omega_e} - \frac{1}{2} \omega_e$$

which gives too large values for I_2 and Br_2 , but only slightly too low for Cl_2 , yields $D_0(F_2) \lesssim 40 \text{ k.eals.}$ in agreement with the values given above.

No anharmonicity nor upper electronic states are taken into account

/although

[‡] Recently (43) a Raman shift $\omega = 892.1 \pm 2 \text{ cm}^{-1}$ has been found in F_2 and accepted as its fundamental frequency. This gives $\omega_0 \sim 920 \text{ cm}^{-1}$ and results in thermodynamic functions which are intermediate between those of ref.(7) and the present values of Table I.

RESTRICTED

although the levels and structures of the first excited states of F_2 may differ from those of the other halogens.

3. Hydrogen fluoride, HF.

The molecular ground state is $^1\Sigma_g^+$. Upper states which must be high are not known. For molecular and spectroscopic data (cf. 15) $\omega_0 = 4050.4$, $x_0\omega_0 = 90.9$; $B_0 = 20.542$ giving $r_0 = 0.917$ and $I_0 = 1.362$.

The thermodynamic functions are those by Murphy and Vance (7) with slight corrections for the new values of the universal constants.

Equilibrium constants K_f^0 have been calculated with the new value (17, 27) $\Delta H_f^0(HF) = -64.5$ k.cals. With the new $D(F_2) = 40$ or 32.4 k.cals. this corresponds to $D(HF) = 136.1$ or 132.3 k.cals. and to the electronegativity differences (24) $X_{HF} = D(HF) - [D(H_2) \cdot D(F_2)]^{1/2} = 72.7$ or 75.3 k.cals. in agreement with the high dipole moment $\mu = 1.91$.

4. Chlorine mono fluoride, ClF.

Wahrhaftig (19) and, more recently, Schmitz and Schumacher (9) have analysed the absorption spectrum. The ground state is Σ_g^+ and a perturbation of the vibrational levels is explained as pre-dissociation (limit ~ 60.8 k.cals.). By comparison with ICl and IBr spectra, Wahrhaftig concludes that the upper state is $^3\Pi_0^+$. The vibrational analysis of (9), (19) is based upon the three most distinct bands at $\sim 21000\text{cm}^{-1}$ and including subsequent diffuse bands, the convergence limit is obtained at 21500cm^{-1} (~ 61.4 k.cals.). The state of the F atoms formed in dissociation has not been established; but if we assume that the F-atoms are excited ($P_{1/2} = 1.1$ k.cals.) the dissociation energy of ClF into normal atoms is $D(FCl) = 60.3$ k.cals.

It might be that the band system actually involves transitions from the $v'' = 1$ ground state level instead of the $v'' = 0$, and this cannot definitely be excluded by applying the Franck-Condon principle to Morse-curves constructed from the known data. In the case of $v'' = 1$ the value of $D_0(\text{ClF})$ would be increased by 2.3 k.cals.; altogether, $D(FCl)$ would not be higher than 64 k.cals. and $D(F_2)$ not higher than 45 k.cals. Compared with the available experimental evidence, Wicke's (58) recent argument in favour of $D(F_2) = 63$ k.cals. is not convincing.² The data for the two states of ClF is:-

$$x \ ^1\Sigma_g^+ : B_0 = 0.518; \alpha_0 = 0.006; \omega_0 = 793.2 (780.4); x_0\omega_0 = 9.9 (4.0);$$

$$r_0 = 1.625; \omega_0 = 783 (776); r_0 = 1.630; I_0 = 54.35$$

$$A \ ^3\Pi_0^+ : B_0 = 0.327; \alpha_0 = 0.014; \omega_0 = 313.5 (316.4); x_0\omega_0 = 2.22 (11.8);$$

$$r_0 = 1.92; \omega_0 = 311 (305); r_0 = 1.93;$$

/Values

X Recent infra red and Raman studies (62) confirm the above frequency of the ground state of ClF and therefore support the value $D(FCl) = 60.3$ k.cals.

RESTRICTED

Values in brackets are from (9). The micro-wave spectrum of FCl (28) agrees excellently with Wahrhaftig's rotational analysis. Wells (56) calculated $r(\text{FCl}) = 1.62$ from Shomaker & Stevenson's (59) law for bond lengths. The dipole moment (28) is $\mu = 0.88$ in agreement with a certain amount of ionic contribution to the bond energy, $x_{\text{FCl}} = D(\text{FCl}) - [D(\text{F}_2) \cdot D(\text{Cl}_2)]^{1/2} = 15$ k.cals.

Thermodynamic data have been calculated by Potter (29) in the HORR approximation up to 2000°K . from Wahrhaftig's data with corrections for the isotopy of Cl. These data are given in the appendix; they do not contain the mixing term for isotopy $S_{\text{mix}} = 1.109$. The Π state has been neglected since, even at 2000°K . it has only a minor influence on the thermodynamic functions. The correction for isotopy is of a bigger order but still small.

Equilibrium constants K_f have been calculated with the two values

$$\Delta H_f^{\circ}(\text{FCl})_{\text{sc}} = -11.6 \text{ and } -15.0 \text{ k.cals.} = \Delta H_f^{\circ}(\text{FCl})$$

according to (20) and (9) respectively, since a decision between these two values is not possible at the moment. Perhaps a comparison of the two theoretical temperatures in the reaction $\text{Cl}_2 + \text{F}_2 \rightarrow 2\text{ClF}$, corresponding to the alternative values $\Delta H_f^{\circ}(\text{FCl})$, with an experimentally determined one, could settle the dispute. A third value $\Delta H_f^{\circ} = -13.9$ k.cals. is obtained by the combination of $\Delta H_f(\text{NaF}) = -138.2$ and $\Delta H_f(\text{NaCl}) = -99.8$ k.cals. (55) with the enthalpy change $\Delta H = -24.5$ k.cals. (9) for the reaction

At the time of this investigation Ward and Hussey (57) published thermodynamic functions of FCl from 2000 up to 5000°K . calculated with $\omega_0 = 773$, $I_0 = 54.35$ by the HORR approximation, and, including the Π state ($P_{\text{El}} = 6$). Their equilibrium constants are based on $\Delta H_f^{\circ}(\text{FCl}) = -15.0$ k.cals.

5. Bromine fluoride, BrF.

Vibrational analysis (25) gives $\omega_0 = 665$ and $X_0\omega_0 = 3$ for the $^1\Sigma^+$ ground state. As a rotational analysis has not been made, the value $r_0 = 1.85$ is used, calculated from bond radii (24) * which gives a moment of inertia $I_0 = 87.23$.

The thermodynamic functions in the appendix do not include upper states, correction for the anharmonicity of vibration or the effect of isotope mixing. The error thus incurred is probably not serious.

/The

* A recent micro-wave analysis (63) gives $r_e = 1.759$ and $I_e = 78.355$ for Br^{79}F . This corresponds to $I_0 = 79.0$ and requires a reduction of the values for S and (F) in Table I by 0.199 units.

RESTRICTED

The energy of dissociation is $D(\text{BrF}) = 50.3$ or 59.9 k.cals. (25) depending on whether F or Br is the excited one of the dissociation product. If we discard the second value, then, according to the value of $D(\text{F}_2)$ chosen, we obtain $\Delta H_f^\circ(\text{BrF}) = -7.6$ or -11.4 k.cals. The first value, corresponding to $D(\text{F}_2) = 40$ k.cals. has been used in calculating the equilibrium constants of formation.

6. Boron mono-fluoride, BF.

The ground state is $^1\Sigma$ (44) in contrast to the earlier assignment $^3\Pi$ (15), therefore $P_{EO} = 1$, $S = 1$.

$r_o(\text{B-F}) = 1.30$ is used (50), whereas $r_o(\text{B-F})$ is equal to 1.29 in BF_3 and $= 1.32$ in BF in the hypothetical $^3\Pi$ state; thus $I_o = 19.34$.

Bibliography (44) gives also $\omega_o = 1400$, instead of the previous value of 1314 and $\omega_o X_o = 12$. The first excited state is at 51083 cm^{-1} (~ 147 k.cals.) so that it need not be taken into account below 4000 K .

The previous value (45) of the bond energy $D(\text{BF}) \sim 105$ k.cals. is probably incorrect. Linear Birge-Sponer extrapolation gives ~ 140 k.cals. which is also the order of the average dissociation energy of BF bonds in BF_3 . The enthalpy of formation is

$$\Delta H_f^\circ(\text{BF}) = \Delta H_f^\circ(\text{F}) + \Delta H_f^\circ(\text{B}_{\text{gas}}) - D(\text{BF}) \sim 115 - D(\text{BF}) \sim -25 \text{ k.cals.}$$

whereas (18) gives -18 k.cals.; the former value is used in the calculation of equilibrium constants. The values of the thermodynamic functions of BF are given in the Appendix; they do not include the mixing term $S_{\text{mix}} = 0.989$ and the influence of isotopy on I and ω is omitted since this data is not of high accuracy. The thermodynamic functions of BF, which are put forward by Ward and Hussey (57) for the temperature ranges $300-2000^\circ\text{K}$. and $2000 - 5000^\circ\text{K}$. respectively are incorrect since they imply a $^3\Pi$ ground state.

7. Beryllium-monofluoride, BeF.

Molecular data (11,15,52): $^2\Sigma$, $C_{\infty v}$, $P_{EO} = 1$, $S = 1$, $r_o(\text{BeF}) = 1.35$, $\omega_o = 1256.5$, $I_o = 18.70$.

$H_f^\circ(\text{BeF})$ is not known, $D(\text{BeF})$ is very uncertain. Linear Birge-Sponer extrapolation of vibrational data gives $D(\text{BeF}) = 102$, whereas Herzberg (15) records ~ 125 k.cals. From thermochemical data and average bond energies in BeF_2 the value $D(\text{BeF}) \sim 145$ k.cals. is obtained as an upper limit. It may be that the first bond in BeF_2 is stronger than the second one (cf. 54) so that Herzberg's figure would be of the right order. In view of this uncertainty no values of K_f° have been calculated.

8. Fluorine monoxide, F₂O.

The thermodynamic functions given in Appendix are those calculated by Potter (29) with the molecular data:-

RESTRICTED

$${}^1\Sigma, C_{2v}, P_{EO} = 1, S = 2, \omega_0 = 833, 492, 1110 \text{ cm}^{-1}, r_0(\text{F-O}) \\ = 1.41 \pm 0.05 \text{ \AA}, \text{ angle } \overset{\text{A}}{\text{FOF}} = 100 \pm 5^\circ, I_A = I_B + I_C = 88.95, \\ I_B = 73.59, I_C = 15.35.$$

Probably the value $r(\text{O-F}) = 1.41$ is too high (57); the lower limit would result in values of $\langle F \rangle$ and S which are smaller by 0.216 than those given in the Appendix.

Equilibrium constants of formation have been calculated with the enthalpy of formation $\Delta H_f^\circ(\text{OF}_2) = +6.08 \text{ k.cals.}$ which is the most probable mean value (29).

9. Tri-fluorides of the 5th group of the periodic table, XF_3 .

The ground state is ${}^1\Sigma$; point group C_{3v} (pyramidal), $P_{EO} = 1, S = 3$. Spectroscopic and molecular data (in general cf. 11,22,23):

Molecule	Bond Lengths	Angle FXF	Moments of Inertia	Vibrational Frequencies
NF_3	1.34	110	152.0, 79.6, 79.6	420(2), 505(1), 908(1)
PF_3	1.52	104	176, 107, 107	486(2), 531(1), 840(2), 890(1)
AsF_3	1.712 (1.72)	100	216.9, 142.8, 142.8, (220), (145), (145)	274(2), 341(1), 644(2), 707(1)
SbF_3	(1.95)	(105)		(620)
BiF_3	(2.1)	(110)		(550)

Thermodynamic functions for NF_3 have been calculated with $r(\text{N-F}) = 1.34$ (26). The distances $r(\text{F-N}) = 1.37$ or 1.45 (ref.57) would increase the values of $\langle F \rangle$ and S by 0.12 or 0.57 respectively. $\Delta H_{298.15}^\circ(\text{NF}_3) = -27.2 \text{ k.cals.}$ from (18) gives $\Delta H_f^\circ(\text{NF}_3) = -26.0 \text{ k.cals.}$ with the present data. Earlier data for PF_3 are by Stevenson and Yost (30) and our slight differences are due to the use of revised physical constants. $\Delta H_f^\circ(\text{PF}_3) = -227 \text{ k.cals.}$ from a comparison of bond energies. AsF_3 is 100% ionic FAsF_2 (31). Thermodynamic functions of AsF_3 at 298.16°K. are given in (18) which agree with our own data. $\Delta H_{298.16}^\circ = -218.3$ (18) gives $\Delta H_f^\circ(\text{AsF}_3) = -217 \text{ k.cals.}$ This value and $r(\text{AsF}) = 1.712$ (31) have been used in the calculations. The data for SbF_3 and BiF_3 are not adequate for thermodynamic calculations. $\Delta H_f^\circ(\text{SbF}_3) \sim -205 \text{ k.cals.}$

/10.

RESTRICTED

10. Hexa-fluorides of the 6th group.

The ground state is $^1\Sigma$, point group O_h , $P_{EO} = 1$, $S = 24$;
 $I_A = I_B = I_C = I$. Molecular data (11,22,23,52).

Molecule	Bond Length	Moments of Inertia	Vibrational Frequencies	$-\Delta H_f^\circ_{298.16}$	$S^\circ_{298.16}$
SF_6	1.57	305	363(3), 617(3), 525(3), 645(2), 775(1), 965(3)	262	69.6
SeF_6	1.68	349	245(3), 461(3), 405(3), 662(2), 708(1), 787(3)	246	75.1
TeF_6	1.83	415	165(3), 370(3), 313(3), 674(2), 701(1), 752(3)	315	80.8

Meyey and Buell (51) have calculated the thermodynamic functions of SF_6 between 600 and 5000°K.: their data is fitted by:

$$C_p^\circ = 37.41 + 0.0876 \times 10^{-3} T - 18.78 \times 10^{-5} \times T^2$$

For the formation of SF_6 from $S_2(g)$ and $F_2(g)$ they give:

$$\Delta F^\circ = -271.800 - 11.33 \times T \times \ln T + 1.678 \times 10^{-3} T^2 + 9.39 \times 10^5 \times T^{-1} + 171.2 \times T$$

$$\Delta H^\circ = -271.100 - 11.33 \times T - 1.678 \times 10^{-3} \times T^2 + 18.78 \times 10^5 \times T^{-1}$$

Schumb (41) gives some thermochemical properties of SF_6 at low temperatures. In the above table the $-\Delta H_f^\circ$'s and S° 's at 298.16°K. are taken from (18). The value of $S^\circ_{298.16}$ for SF_6 compares well with the figure given in the Appendix (cf. 53 for experimental values). The value $C_p^\circ(SF_6) = 21.57$ at 298.16 as given in (18) is too low and the C_p° values from (51) agree very well with the present calculations.

11. Boron trifluoride, BF_3 .

Ground state $^1\Sigma$, point group D_{3h} (plane symmetrical), $P_{EO} = 1$, $S = 6$.
 $r(B-F) = 1.29$, $FBF = 120^\circ$, $I_A = 158$, $I_B = I_C = I_A/2 = 78.9$, vibrational frequencies (22,23) $\omega = 886, 700, 1450(2), 480(2)$. The thermodynamic functions (F) and S are taken from (42), the mixing term for isotopy is not included. According to (18), $\Delta H_f^\circ_{298.16}(BF_3) = -265.4$ which gives $\Delta H_f^\circ(BF_3) = -267.0$ k.cals. and an average dissociation energy of BF bonds of 140 k.cals. Instead of K_f° the equilibrium constants K_p for the reaction $BF_3 \rightarrow BF + F_2$ have been calculated with $\Delta H = +242$ k.cals. Bibliography (57) evaluated K_p 's for the reaction $BF_3 \rightarrow BF + 2F$ with $\Delta H = +355.0$ k.cals. whereas our new ΔH_f values lead to $\Delta H = +282$ k.cals.

/12.

12. Chlorine trifluoride, ClF₃.

The molecular ground state is assumed to be $^1\Sigma$ with $P_{EO} = 1$. Recently (21) the infra-red and Raman-spectra of ClF₃ have been investigated but no analysis was made in view of the complex character of the bands due partly to molecular association in the liquid phase (9, 21). Another spectroscopic investigation (32) gives the following information:-

$$\omega_1 = 508; \omega_{2,4} = 750, \omega_{3,5} = 316; \omega_4 = 428; \text{mean moment of inertia}$$

$$\bar{I} = 130 \text{ with an estimated error of about } 10\%.$$

These frequencies were used in calculating the thermodynamic functions of ClF₃. A pyramidal C_{3v} structure was assumed in agreement with the appearance of 4 Raman active frequencies and the existence of the dimer - possibly F₂Cl-ClF₃ (with contributions from F₃Cl-ClF₃) in agreement with the low heat of polymerisation (33). The angle FClF was assumed $\sim 110^\circ$ and $r_0(\text{Cl-F}) = 1.63$ i.e. the same as in ClF, although this leads to the rather high moments of inertia $I_A = 225, I_B = I_C = 122.5, \bar{I} = 150$.

The following values have been quoted for the heat of formation of ClF₃ at 298.16°K: -42.0 ± 1.5 (33), -37.1 (32), -28.4 k.cals. (27). The mean value $\Delta H_f^\circ(\text{ClF}_3) = -36$ k.cals. was used for calculating equilibrium constants.

13. Silicon tetra-fluoride, SiF₄.

The ground state is $^1\Sigma$; point group T_d, $P_{EO} = 1, S = 12$. Tetrahedral

angles FSiF = $109^\circ 28'$ and nuclear distances $r_0(\text{Si-F}) = 1.54$ (39) give the moments of inertia $I_A = I_B = I_C = (8/3)(M_F/N) = 199.5$ (N = Avogadro number). The vibrational frequencies (22, 23) are:- $\omega = 800, 260(2), 1022(3), 420(3)$. Earlier values (18, 40) of S at 298.16°K. are somewhat higher than our value. It is not known whether these earlier values include the mixing term $S_{\text{mix}} = 0.304$, which is not contained in the figures given in the Appendix. In calculating the equilibrium constants $\Delta H_f^\circ(\text{SiF}_4) = -373$ k.cals. has been used (cf. $\Delta H_f^\circ_{298.16} = -370$ k.cals in (18)).

14. Carbon tetra-fluoride, CF₄.

The ground state is $^1\Sigma$, point group T_d, $P_{EO} = 1, S = 12$. No upper states need be considered because of the absence of absorption in the near ultra-violet.

Tetrahedral angles FCF = $109^\circ 28'$ and bond distances $r(\text{C-F}) = 1.36$ give the moments of inertia $I_A = I_B = I_C = 154.8$. The vibrational frequencies (22, 23) are:- $\omega = 904, 437(2), 1265(3), 630(3)$ (cf. 34 for force constants). The C-F bonds are mainly covalent but there is some resonance

with FCF₃ (24). The enthalpy of formation has been amended from -164 (11, 18) to $\Delta H_f^\circ(\text{CF}_4) = -231 \pm 3$ k.cals. (27) and this value has been used as ΔH_f° in calculating the equilibrium constants. The entropy figure at

/300°K.

RESTRICTED

300°K. agrees well with that given in (18).

15. Carbon-oxyfluoride, COF₂.

The most probable structure is ¹Z; point group C_{2v}, with P_{EO} = 1 and S = 2 as in COCl₂ and COBr₂. FCF = 115° r_o(C-O) = 1.27 and r_o(C-F) = 1.38 have been assumed and these give I_A = 75.89, I_B = 85.47, I_C = I_A + I_B = 161.45. It may well be that r(C-F) is as small as ~1.32 or even smaller, as is suggested by comparing r(C-X) in the series COX₂, (X = Cl, Br) with the normal bond length r(C-X). As this procedure is open to criticism the average r(C-F) = 1.38 has been preferred.

Recently (35) infra-red and Raman bands of COF₂ have been communicated but no analysis was made. The following six frequencies have been used in the calculations, ω = 580, 626, 775, 965, 1249, 1941 cm⁻¹. The enthalpy of formation was taken as ΔH_f^o(COF₂) = -150 k.cals. in good agreement with the experimental value of (27). This corresponds roughly to the same value D(C-O) ~ 158 k.cals. in COF₂ and COCl₂ calculated from average bond energies.

16. Hexafluoroethane, C₂F₆.

The structure is either staggered D_{3d} or eclipsed D_{3h} both having the symmetry number S = 6.

The vibrational frequencies and their assignment are (36) ω₁ = 1420, ω₂ = 809, ω₃ = 349, ω₅ = 1117, ω₆ = 714, ω₇ = 1250(2), ω₈ = 523(2), ω₉ = 216(2), ω₁₀ = 1237(2), ω₁₁ = 620(2), ω₁₂ = 380(2): (force constants cf. 34). The torsional frequency ω₄ is not known, since it is inactive in both infra-red and Raman spectrum.

Unfortunately the bond distances are not known with accuracy. The normal distances r(C-C) = 1.54 and r(C-F) = 1.36 (24) have been found to give vibrational frequencies for the Urey-Bradley field which agree well with the experimental ones (46). This method, however, does not include the interaction of the two CF₃ groups. According to (47) the distances r(C-C) = 1.45 (37) and r(C-F) = 1.35 are not in very good agreement with magnetic measurements on the solid crystal. An even smaller r(C-F) (48) would however improve this situation.

Tetrahedral angles FCF = 109° 28' have been assumed, r(C-F) = 1.35, r(C-C) = 1.45 in agreement with (37), giving I_A = 306.7, I_B = I_C = 435.5. The normal values of r(C-C) = 1.54, r(C-F) = 1.36 would give (36), I_A = 311.2, I_B = I_C = 462.4, whereas a Gerhard & Dennison extrapolation of measurements on the Q, P and R branches give I_A = 98, I_B = I_C = 401 which are obviously too low.

The contribution from the internal movement about the C-C axis depends on whether this movement is a torsional oscillation or a free or hindered internal rotation. Since no spectroscopic nor calorimetric measurements are available we can only estimate this contribution. It will be assumed that there is an internal rotation restricted by a potential barrier of estimated height V ~ 3500 cal. The reduced moment of inertia in internal rotation is I_r = I_A/4 ~ 76.7 and the symmetry number S = 3, corresponding to 3 equivalent positions of the two CF₃ groups relative to each other. With n = 3 equal and equidistant maxima, the potential V ~ 3.5 k.cals. corresponds to the torsional frequency ω_r = (n/2π)(V/2I_r)² ~ 75 cm⁻¹. In the

/following

RESTRICTED

following table (cf. Appendix 3, Sec. VIII) the contributions from this frequency (ν) are compared with those for free (f) and restricted (r) internal rotation, the latter increments being calculated from Pitzer's tables (cf. 51) with $V = 3500$, and $10^{-36} \times n^2/I_r V = 0.335$.

As an approximation the problem is treated as an equilibrium between the oscillating staggered D_{3d} form, which also occurs in the similar C_2Cl_6 molecule (38), and the form having restricted internal rotation, viz:-

$$C_2F_6(D_{3d}, \text{osc.}) \rightleftharpoons C_2F_6(\text{rot.}); K \equiv [C_2F_6(\text{rot.})] / [C_2F_6(\text{osc.})] \equiv X/(1-X);$$

$$X \equiv [C_2F_6(\text{rot.})] = K/(K + 1) \text{ and}$$

$$R \ln K = (F)r - (F)\nu - \Delta H^\circ/T; \Delta H^\circ = V/2 - w_r/2 = 1650 \text{ cal.}$$

The corresponding values of K and X are listed in the last column of Table 3. The thermodynamic functions of C_2F_6 in the Appendix have been obtained by combining the functions of the two forms according to their molar fractions. In view of the general uncertainty of the other data this procedure was thought satisfactory, although, strictly speaking in the transitional region one ought to calculate (F) etc. from the partition function with eigen values of E_r from the wave-equation (Mathieu equation).

The old value of $\Delta H_f(C_2F_6) = 240$ k.cals. (18) is definitely wrong. With the new $\Delta H_f^\circ(CF_4) = -231$ k.cals. the approximate value $\Delta H_f^\circ(C_2F_6) = -315$ k.cals. was derived by using average bond energies $D(C-F) = 107$, and $D(C-C) = 67$ k.cals. according to the shorter bond in C_2F_6 .

V. DISCUSSION OF RESULTS.

1. The equilibrium constants K_f° of formation of F and HF replace earlier erroneous data (60). F_2 and HF are more dissociated at high temperature than previously assumed. Above $1500-2000^\circ K$. fluorine should behave as a monatomic gas.

2. The final reaction temperature of the process

which was used (20) to determine $\Delta H_f^\circ(ClF)$, is 1660 or $2080^\circ K$. depending on whether $\Delta H_f^\circ(ClF) = -11.6$ or -15.0 k.cals. respectively. At the higher temperature dissociation of ClF into atoms amounts to ~ 2 per cent at 1 atm. pressure.

3. Apart from dissociation, the formation of ClF_3 may have influenced Wicke's (20) measurement of $\Delta H_f^\circ(ClF)$ to an even larger extent, especially if $-\Delta H_f^\circ(ClF_3)$ is larger than $+36$ k.cals., the figure accepted. From this it appears that $-\Delta H_f^\circ(ClF) = +11.6$ may be slightly too low.

4. At temperatures below $800-900^\circ K$. the formation of NF_3 is thermodynamically possible. Apparently kinetic conditions are unfavourable, an obstacle, however which might be overcome as in the synthesis of ammonia.

/5.

RESTRICTED

5. CF_4 and COF_2 are formed easily from F_2 and either C (solid) or CO. Under comparable conditions CF_4 is the major product.

6. The equilibrium constants for the reactions:-

are given in the Appendix; these equilibria correspond to the water-gas equilibrium in the oxidation of hydrocarbons.

7. Both the equilibria

and

behave rather differently from the corresponding reaction

8. The equilibrium constants for the reaction

show that this reaction occurs to a very small extent in comparison with the hydrocarbons.

9. The special behaviour of most of the equilibria under (6) and (7) together with those of the reactions

might explain some of the peculiarities of the combustion of organic fluorine compounds. As a practical result it can be concluded that the lower per-fluorinated paraffins are reasonably stable to dry oxygen up to fairly high temperatures but may react with H_2 or H_2O .

AD#:

Date of Search: 13 February 2007

Record Summary:

Title: Thermodynamic functions of fluorine and some of its compounds
Covering dates 1950 July
Availability Open Document, Open Description, Normal Closure before FOI
Act: 30 years
Former reference (Department) ERDE 2/M/50
Held by The National Archives, Kew

This document is now available at the National Archives, Kew, Surrey, United Kingdom.

DTIC has checked the National Archives Catalogue website (<http://www.nationalarchives.gov.uk>) and found the document is available and releasable to the public.

Access to UK public records is governed by statute, namely the Public Records Act, 1958, and the Public Records Act, 1967.
The document has been released under the 30 year rule.
(The vast majority of records selected for permanent preservation are made available to the public when they are 30 years old. This is commonly referred to as the 30 year rule and was established by the Public Records Act of 1967).

This document may be treated as **UNLIMITED**.
