LONG-TERM GOALS

My long-term goals are to develop a physical understanding of the processes which lead to mixing in the ocean, with the aim of using this understanding to develop parameterizations of mixing suitable for global and regional models, and applying such models to societally relevant problems. A particular focus is the mixing induced by tidal flow over topography, and mixing induced by breaking nonlinear internal waves.

OBJECTIVES

The scientific objectives of this study are to explore internal waves generated by tidal flow through straits in the region close to the sill. Our geographic focus will be the Luzon Straits. A particular scientific focus will be nonlinear overturning and breaking within the straits leading to mixing and modification of the wave field. One possibility which we will examine is whether transient internal hydraulic jumps are possible in the Luzon Straits, whether these jumps are released to propagate toward the topography as internal bores when the flow relaxes, and whether the bores lead to local mixing. We will explore the details of the Luzon Strait topography to identify locations particularly conducive to local overturning processes. We will examine how local mixing modifies the character of the internal waves that propagate away from the topography, for example their vertical and horizontal scales. We will also examine the sensitivity of the nonlinear wave response to the local stratification near the sill, and the ambient geostrophic currents. To summarize, our goals are to (a) examine the dependence of nonlinear features and local breaking at the generation site on topographic shape and stratification; (b) evaluate the impact of topographic shape and stratification on the lengthscales and amplitude of the internal wave response to tidal forcing; (c) examine the impact of seasonal variations in stratification and geostrophic currents on the lengthscales and amplitude of the internal tides.

APPROACH

We will employ the nonhydrostatic MITgcm in both 2- and 3-dimensions to carry out simulations of increasing complexity, focusing the resolution on the regions close to the sill where overturning is most likely to occur. The MITgcm is well-suited for this study, having been used for numerous study of nonlinear internal tides (e.g. Legg and Klymak, 2008). Typical resolutions near the sill will be

$O(100\text{m})$ in the horizontal and $O(10\text{km})$ in the vertical, although higher resolutions may be used if needed to capture the features of interest. We will use local computing resources for initial calculations, and apply for Navy supercomputing resources for larger calculations. Initial simulations will focus on providing guidance for the main field program to take place in 2011. The goal will be to identify the locations where mixing is important, and hence where observations would be most interesting. Following the field program, simulations will be carried out to help in interpretation of the observations, with increasing complexity, beginning with 2D simulations with horizontally uniform stratification, and proceeding to 3D simulations with complex realistic topography and ambient stratification. We will collaborate closely with Jody Klymak, and a postdoctoral researcher based at Princeton will carry out much of this work. We will also communicate closely with observationalists involved in the Luzon Straits field experiment.

WORK COMPLETED

Since funding was only awarded this spring, and Legg is only receiving one month's salary per year for this project, progress to date is limited to setting up the MITgcm to carry out initial calculations. Applications for the postdoctoral appointment, due to begin in year 2, are currently being reviewed.

RESULTS

Nothing to report at present.

IMPACT/APPLICATIONS

Nothing to report at present.

RELATED PROJECTS

This work is a component of the Internal Waves in Straits Experiment. We expect to work closely with other IWSE researchers, particularly Jody Klymak. The work is also related to a recently proposed NSF climate process team on internal-wave driven mixing (PI Jen MacKinnon), with which Legg is collaborating.
