

Report Documentation Page				Form Approved OMB No. 0704-0188	
Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

LONG-TERM GOALS

We seek to develop radiation parameterizations for dynamical models that are computationally efficient and work seamlessly across models at all time and space scales, especially from regional models to global models.

OBJECTIVES

We intend to build radiation codes for use in the Navy's limited area model (COAMPS) and global model (NOGAPS/NAVGEM). The codes will be scale-aware, computationally efficient across a range of computer architectures, and operate continuously rather than at discrete time steps.

APPROACH

We are building on two algorithms developed by the PI: Monte Carlo Spectral integration (Pincus and Stevens, 2009) for time continuity and the Monte Carlo Independent Pixel Approximation (Pincus et al., 2003) for sampling sub-grid-scale variability in cloud optical properties.

WORK COMPLETED

We have nearly completed initial development of these codes, which are highly modular. Gas optics come from the state-of-the-art RRTMG radiation parameterization. Cloud optics use lookup tables developed at the Max Planck Institute for Meteorology (Hamburg) though other parameterizations are possible. We have written vectorized longwave (emission/absorption) and shortwave (multiple scattering) solvers and higher-level drivers. We have developed a general method for encapsulating the spectral sampling strategy used by MCSI, including the possibility of using one or more "teams" of spectral points to limit the maximum error realized. We are exploring methods for more accurate and efficient diagnosis of cloud radiative effects.

RESULTS

We are still in the software development and optimization phase.

IMPACT/APPLICATIONS

Once we have reasonably efficient baseline codes we will move to introduce them into Navy forecasting models.
