1518: /*
1519: Description:
1520:     Handling of the SDMReqReg messages. There are two forms of ReqReg calls, one to
perform an exhaustive search
1521:     of all registered xTEDS as a request of an application, and one to perform a search of only
newly registered
1522:     or unregistered xTEDS. These cases are handled when xTEDref is -1 (exhaustive search) or
the index numbered
1523:     value of the xTEDS from which to begin.
1524:
1525: Input:
1526:     MsgBuf - the message in an array
1527:     MsgSize - the length of the message in bytes
1528:     subref - a pointer to a subscription list node
1529:     xTEDref - an index reference to the xTEDS node, this will be -1 if all xTEDS to be searched
for matches
1530:     if this index is >= 0, search only the xTEDS registered in that slot. In this case,
RequesterIPAddr
1531:     and RequesterPort are the address and port of the subscriber.
1532:     RequesterIPAddr - the ip address in dot notation
1533:     RequesterPort - the port to respond on if SDMReqReg.destination.port == 0 &&
SDMReqReg.reply == SDM_CURRENT
1534:     xTEDSAction - One of REGISTRATION_MODIFICATION,
DEREGISTRATION_MODIFICATION, or UPDATE_MODIFICATION when
1535:     the ReqReg is being performed on a subscription to fill the "type" in a SDMRegInfo, or
MOD_NOT_APPLICABLE otherwise
1536:

16:
17:
18: The xTEDSLibraryList class is a linked list of xTEDSLibrary nodes, used by the DataManager to
represent
19: registered devices and applications in the SDM. xTEDSLibrary nodes are dynamically allocated
when a
20: free position in the list doesn't exists, but are not de-allocated when not used. Instead they are marked
21: as unavailable, which allows the position to be reused.

```
1:
2:
3: The backupDMList class is used to keep track of all registered backup DataManagers. Backup
DataManagers receive
4: all copies of SDMxTEDS and SDMCcancelxTEDS messages. This class helps facilitate sending those
messages out.
5: This list is built when SDMReady messages arrive from the backup DMs as heartbeat messages.

File: sdm/sm/sm.cpp

```
1: //*****
2: //Sensor Manager Module of the SDM
3: //
4: //This source is compilable on both a Linux and a Win32 architecture. Throughout, there are
5: //compile switches as #ifdef ... #endif which conditionally add or remove functionality.
6: //The most notable changes for compilation is the removal of a separate signal handling thread
7: //under Win32, because Windows has far fewer options for process signals than Linux.
8: //*****

1: /*****
2:  *   Perl-Compatible Regular Expressions   *
3: *****/
4:
5: /* This file contains character tables that are used when no external tables
6:  are passed to PCRE by the application that calls it. The tables are used only
7:  for characters whose code values are less than 256.
8:
9:  This is a default version of the tables that assumes ASCII encoding. A program
10:  called dftables (which is distributed with PCRE) can be used to build
11:  alternative versions of this file. This is necessary if you are running in an
12:  EBCDIC environment, or if you want to default to a different encoding, for
13:  example ISO-8859-1. When dftables is run, it creates these tables in the
14:  current locale. If PCRE is configured with --enable-rebuild-chartables, this
15:  happens automatically.
16:
17:  The following #includes are present because without the gcc 4.x may remove the
18:  array definition from the final binary if PCRE is built into a static library
19:  and dead code stripping is activated. This leads to link errors. Pulling in the
20:  header ensures that the array gets flagged as "someone outside this compilation
21:  unit might reference this" and so it will always be supplied to the linker. */

36: // C++ interface to the pcre regular-expression library. RE supports
37: // Perl-style regular expressions (with extensions like \d, \w, \s,
38: // ...).
39: //
```

```

40: // -----
41: // REGEXP SYNTAX:
42: //
43: // This module is part of the pcre library and hence supports its syntax
44: // for regular expressions.
45: //
46: // The syntax is pretty similar to Perl's. For those not familiar
47: // with Perl's regular expressions, here are some examples of the most
48: // commonly used extensions:
49: //
50: // "hello (\w+) world" -- \w matches a "word" character
51: // "version (\d+)"    -- \d matches a digit
52: // "hello \s+world"   -- \s matches any whitespace character
53: // "\b(\w+)\b"        -- \b matches empty string at a word boundary
54: // "(?i)hello"        -- (?i) turns on case-insensitive matching
55: // "/\s*(.*)\s*/"     -- .*? matches . minimum no. of times possible
56: //
57: // -----
58: // MATCHING INTERFACE:
59: //
60: // The "FullMatch" operation checks that supplied text matches a
61: // supplied pattern exactly.
62: //
63: // Example: successful match
64: // pcrecpp::RE re("h.*o");
65: // re.FullMatch("hello");
66: //
67: // Example: unsuccessful match (requires full match):
68: // pcrecpp::RE re("e");
69: // !re.FullMatch("hello");
70: //
71: // Example: creating a temporary RE object:
72: // pcrecpp::RE("h.*o").FullMatch("hello");
73: //
74: // You can pass in a "const char*" or a "string" for "text". The
75: // examples below tend to use a const char*.
76: //
77: // You can, as in the different examples above, store the RE object
78: // explicitly in a variable or use a temporary RE object. The
79: // examples below use one mode or the other arbitrarily. Either
80: // could correctly be used for any of these examples.

```

```

81: //
82: // -----
83: // MATCHING WITH SUB-STRING EXTRACTION:
84: //
85: // You can supply extra pointer arguments to extract matched subpieces.
86: //
87: // Example: extracts "ruby" into "s" and 1234 into "i"
88: //   int i;
89: //   string s;
90: //   pcrecpp::RE re("(\\w+):(\\d+)");
91: //   re.FullMatch("ruby:1234", &s, &i);
92: //
93: // Example: does not try to extract any extra sub-patterns
94: //   re.FullMatch("ruby:1234", &s);
95: //
96: // Example: does not try to extract into NULL
97: //   re.FullMatch("ruby:1234", NULL, &i);
98: //
99: // Example: integer overflow causes failure
100: //   !re.FullMatch("ruby:1234567891234", NULL, &i);
101: //
102: // Example: fails because there aren't enough sub-patterns:
103: //   !pcrecpp::RE("(\\w+:\\d+").FullMatch("ruby:1234", &s);
104: //
105: // Example: fails because string cannot be stored in integer
106: //   !pcrecpp::RE("(.*").FullMatch("ruby", &i);
107: //
108: // The provided pointer arguments can be pointers to any scalar numeric
109: // type, or one of
110: //   string      (matched piece is copied to string)
111: //   StringPiece (StringPiece is mutated to point to matched piece)
112: //   T           (where "bool T::ParseFrom(const char*, int)" exists)
113: //   NULL        (the corresponding matched sub-pattern is not copied)
114: //
115: // CAVEAT: An optional sub-pattern that does not exist in the matched
116: // string is assigned the empty string. Therefore, the following will
117: // return false (because the empty string is not a valid number):
118: //   int number;
119: //   pcrecpp::RE::FullMatch("abc", "[a-z]+(\\d+)?", &number);
120: //
121: // -----

```

```

122: // DO_MATCH
123: //
124: // The matching interface supports at most 16 arguments per call.
125: // If you need more, consider using the more general interface
126: // pcrecpp::RE::DoMatch(). See pcrecpp.h for the signature for DoMatch.
127: //
128: // -----
129: // PARTIAL MATCHES
130: //
131: // You can use the "PartialMatch" operation when you want the pattern
132: // to match any substring of the text.
133: //
134: // Example: simple search for a string:
135: //   pcrecpp::RE("ell").PartialMatch("hello");
136: //
137: // Example: find first number in a string:
138: //   int number;
139: //   pcrecpp::RE re("(\\d+)");
140: //   re.PartialMatch("x*100 + 20", &number);
141: //   assert(number == 100);
142: //
143: // -----
144: // UTF-8 AND THE MATCHING INTERFACE:
145: //
146: // By default, pattern and text are plain text, one byte per character.
147: // The UTF8 flag, passed to the constructor, causes both pattern
148: // and string to be treated as UTF-8 text, still a byte stream but
149: // potentially multiple bytes per character. In practice, the text
150: // is likelier to be UTF-8 than the pattern, but the match returned
151: // may depend on the UTF8 flag, so always use it when matching
152: // UTF8 text. E.g., "." will match one byte normally but with UTF8
153: // set may match up to three bytes of a multi-byte character.
154: //
155: // Example:
156: //   pcrecpp::RE_Options options;
157: //   options.set_utf8();
158: //   pcrecpp::RE re(utf8_pattern, options);
159: //   re.FullMatch(utf8_string);
160: //
161: // Example: using the convenience function UTF8():
162: //   pcrecpp::RE re(utf8_pattern, pcrecpp::UTF8());

```

```

163: // re.FullMatch(utf8_string);
164: //
165: // NOTE: The UTF8 option is ignored if pcre was not configured with the
166: // --enable-utf8 flag.
167: //
168: // -----
169: // PASSING MODIFIERS TO THE REGULAR EXPRESSION ENGINE
170: //
171: // PCRE defines some modifiers to change the behavior of the regular
172: // expression engine.
173: // The C++ wrapper defines an auxiliary class, RE_Options, as a vehicle
174: // to pass such modifiers to a RE class.
175: //
176: // Currently, the following modifiers are supported
177: //
178: // modifier      description      Perl corresponding
179: //
180: // PCRE_CASELESS  case insensitive match  /i
181: // PCRE_MULTILINE multiple lines match    /m
182: // PCRE_DOTALL    dot matches newlines    /s
183: // PCRE_DOLLAR_ENDONLY $ matches only at end  N/A
184: // PCRE_EXTRA     strict escape parsing   N/A
185: // PCRE_EXTENDED  ignore whitespaces     /x
186: // PCRE_UTF8      handles UTF8 chars     built-in
187: // PCRE_UNGREEDY  reverses * and *?      N/A
188: // PCRE_NO_AUTO_CAPTURE disables matching parens N/A (*)
189: //
190: // (For a full account on how each modifier works, please check the
191: // PCRE API reference manual).
192: //
193: // (*) Both Perl and PCRE allow non matching parentheses by means of the
194: // "?" modifier within the pattern itself. e.g. (?:ab|cd) does not
195: // capture, while (ab|cd) does.
196: //
197: // For each modifier, there are two member functions whose name is made
198: // out of the modifier in lowercase, without the "PCRE_" prefix. For
199: // instance, PCRE_CASELESS is handled by
200: // bool caseless(),
201: // which returns true if the modifier is set, and
202: // RE_Options & set_caseless(bool),
203: // which sets or unsets the modifier.

```

```

204: //
205: // Moreover, PCRE_EXTRA_MATCH_LIMIT can be accessed through the
206: // set_match_limit() and match_limit() member functions.
207: // Setting match_limit to a non-zero value will limit the execution of
208: // pcre to keep it from doing bad things like blowing the stack or taking
209: // an eternity to return a result. A value of 5000 is good enough to stop
210: // stack blowup in a 2MB thread stack. Setting match_limit to zero will
211: // disable match limiting. Alternately, you can set match_limit_recursion()
212: // which uses PCRE_EXTRA_MATCH_LIMIT_RECURSION to limit how much pcre
213: // recurses. match_limit() caps the number of matches pcre does;
214: // match_limit_recursion() caps the depth of recursion.
215: //
216: // Normally, to pass one or more modifiers to a RE class, you declare
217: // a RE_Options object, set the appropriate options, and pass this
218: // object to a RE constructor. Example:
219: //
220: //   RE_options opt;
221: //   opt.set_caseless(true);
222: //
223: //   if (RE("HELLO", opt).PartialMatch("hello world")) ...
224: //
225: // RE_options has two constructors. The default constructor takes no
226: // arguments and creates a set of flags that are off by default.
227: //
228: // The optional parameter 'option_flags' is to facilitate transfer
229: // of legacy code from C programs. This lets you do
230: //   RE(pattern, RE_Options(PCRE_CASELESS|PCRE_MULTILINE)).PartialMatch(str);
231: //
232: // But new code is better off doing
233: //   RE(pattern,
234: //       RE_Options().set_caseless(true).set_multiline(true)).PartialMatch(str);
235: // (See below)
236: //
237: // If you are going to pass one of the most used modifiers, there are some
238: // convenience functions that return a RE_Options class with the
239: // appropriate modifier already set:
240: // CASELESS(), UTF8(), MULTILINE(), DOTALL(), EXTENDED()
241: //
242: // If you need to set several options at once, and you don't want to go
243: // through the pains of declaring a RE_Options object and setting several
244: // options, there is a parallel method that give you such ability on the

```

```

245: // fly. You can concatenate several set_XXXXXX member functions, since each
246: // of them returns a reference to its class object. e.g.: to pass
247: // PCRE_CASELESS, PCRE_EXTENDED, and PCRE_MULTILINE to a RE with one
248: // statement, you may write
249: //
250: // RE(" ^ xyz \s+ .* blah$", RE_Options()
251: //         .set_caseless(true)
252: //         .set_extended(true)
253: //         .set_multiline(true)).PartialMatch(sometext);
254: //
255: // -----
256: // SCANNING TEXT INCREMENTALLY
257: //
258: // The "Consume" operation may be useful if you want to repeatedly
259: // match regular expressions at the front of a string and skip over
260: // them as they match. This requires use of the "StringPiece" type,
261: // which represents a sub-range of a real string. Like RE, StringPiece
262: // is defined in the pcrecpp namespace.
263: //
264: // Example: read lines of the form "var = value" from a string.
265: // string contents = ...;           // Fill string somehow
266: // pcrecpp::StringPiece input(contents); // Wrap in a StringPiece
267: //
268: // string var;
269: // int value;
270: // pcrecpp::RE re("(\\w+) = (\\d+)\\n");
271: // while (re.Consume(&input, &var, &value)) {
272: //     ...;
273: // }
274: //
275: // Each successful call to "Consume" will set "var/value", and also
276: // advance "input" so it points past the matched text.
277: //
278: // The "FindAndConsume" operation is similar to "Consume" but does not
279: // anchor your match at the beginning of the string. For example, you
280: // could extract all words from a string by repeatedly calling
281: // pcrecpp::RE("(\\w+)").FindAndConsume(&input, &word)
282: //
283: // -----
284: // PARSING HEX/OCTAL/C-RADIX NUMBERS
285: //

```

```

286: // By default, if you pass a pointer to a numeric value, the
287: // corresponding text is interpreted as a base-10 number. You can
288: // instead wrap the pointer with a call to one of the operators Hex(),
289: // Octal(), or CRadix() to interpret the text in another base. The
290: // CRadix operator interprets C-style "0" (base-8) and "0x" (base-16)
291: // prefixes, but defaults to base-10.
292: //
293: // Example:
294: // int a, b, c, d;
295: // pcrecpp::RE re("(.*)(.*)"(.*)");
296: // re.FullMatch("100 40 0100 0x40",
297: //             pcrecpp::Octal(&a), pcrecpp::Hex(&b),
298: //             pcrecpp::CRadix(&c), pcrecpp::CRadix(&d));
299: // will leave 64 in a, b, c, and d.
300: //
301: // -----
302: // REPLACING PARTS OF STRINGS
303: //
304: // You can replace the first match of "pattern" in "str" with
305: // "rewrite". Within "rewrite", backslash-escaped digits ( \1 to \9)
306: // can be used to insert text matching corresponding parenthesized
307: // group from the pattern. \0 in "rewrite" refers to the entire
308: // matching text. E.g.,
309: //
310: // string s = "yabba dabba doo";
311: // pcrecpp::RE("b+").Replace("d", &s);
312: //
313: // will leave "s" containing "yada dabba doo". The result is true if
314: // the pattern matches and a replacement occurs, or false otherwise.
315: //
316: // GlobalReplace() is like Replace(), except that it replaces all
317: // occurrences of the pattern in the string with the rewrite.
318: // Replacements are not subject to re-matching. E.g.,
319: //
320: // string s = "yabba dabba doo";
321: // pcrecpp::RE("b+").GlobalReplace("d", &s);
322: //
323: // will leave "s" containing "yada dada doo". It returns the number
324: // of replacements made.
325: //
326: // Extract() is like Replace(), except that if the pattern matches,

```

```

327: // "rewrite" is copied into "out" (an additional argument) with
328: // substitutions. The non-matching portions of "text" are ignored.
329: // Returns true iff a match occurred and the extraction happened
330: // successfully. If no match occurs, the string is left unaffected.
331:
332:
333: #include <string>

202: /*****
203: *****/
204:         RECURSION IN THE match() FUNCTION
205:
206: The match() function is highly recursive, though not every recursive call
207: increases the recursive depth. Nevertheless, some regular expressions can cause
208: it to recurse to a great depth. I was writing for Unix, so I just let it call
209: itself recursively. This uses the stack for saving everything that has to be
210: saved for a recursive call. On Unix, the stack can be large, and this works
211: fine.
212:
213: It turns out that on some non-Unix-like systems there are problems with
214: programs that use a lot of stack. (This despite the fact that every last chip
215: has oodles of memory these days, and techniques for extending the stack have
216: been known for decades.) So...
217:
218: There is a fudge, triggered by defining NO_RECURSE, which avoids recursive
219: calls by keeping local variables that need to be preserved in blocks of memory
220: obtained from malloc() instead instead of on the stack. Macros are used to
221: achieve this so that the actual code doesn't look very different to what it
222: always used to.
223:
224: The original heap-recursive code used longjmp(). However, it seems that this
225: can be very slow on some operating systems. Following a suggestion from Stan
226: Switzer, the use of longjmp() has been abolished, at the cost of having to
227: provide a unique number for each call to RMATCH. There is no way of generating
228: a sequence of numbers at compile time in C. I have given them names, to make
229: them stand out more clearly.
230:
231: Crude tests on x86 Linux show a small speedup of around 5-8%. However, on
232: FreeBSD, avoiding longjmp() more than halves the time taken to run the standard
233: tests. Furthermore, not using longjmp() means that local dynamic variables
234: don't have indeterminate values; this has meant that the frame size can be
235: reduced because the result can be "passed back" by straight setting of the
236: variable instead of being passed in the frame.

1791: *           Check for POSIX class syntax          *
1792: *****/
1793:
1794: /* This function is called when the sequence "[" or "[". or "["= is
1795: encountered in a character class. It checks whether this is followed by a
1796: sequence of characters terminated by a matching "]" or ".]" or "=]". If we

```

1797: reach an unescaped ']' without the special preceding character, return FALSE.

1798:

1799: Originally, this function only recognized a sequence of letters between the

1800: terminators, but it seems that Perl recognizes any sequence of characters,

1801: though of course unknown POSIX names are subsequently rejected. Perl gives an

1802: "Unknown POSIX class" error for [:f\oo:] for example, where previously PCRE

1803: didn't consider this to be a POSIX class. Likewise for [:1234:].

1804:

1805: The problem in trying to be exactly like Perl is in the handling of escapes. We

1806: have to be sure that [abc[:x\]pqr] is **not** treated as containing a POSIX

1807: class, but [abc[:x\]pqr:] is (so that an error can be generated). The code

1808: below handles the special case of \], but does not try to do any other escape

1809: processing. This makes it different from Perl for cases such as [:l\lower:]

1810: where Perl recognizes it as the POSIX class "lower" but PCRE does not recognize

1811: "l\lower". This is a lesser evil than not diagnosing bad classes when Perl does,

1812: I think.

1875:  *      Adjust OP_RECURSE items in repeated group      *
1876: *****/
1877:
1878: /* OP_RECURSE items contain an offset from the start of the regex to the group

```

1879: that is referenced. This means that groups can be replicated for fixed
1880: repetition simply by copying (because the recursion is allowed to refer to
1881: earlier groups that are outside the current group). However, when a group is
1882: optional (i.e. the minimum quantifier is zero), OP_BRAZERO or OP_SKIPZERO is
1883: inserted before it, after it has been compiled. This means that any OP_RECURSE
1884: items within it that refer to the group itself or any contained groups have to
1885: have their offsets adjusted. That one of the jobs of this function. Before it
1886: is called, the partially compiled regex must be temporarily terminated with
1887: OP_END.

1888:

1889: This function has been extended with the possibility of forward references for
1890: recursions and subroutine calls. It must also check the list of such references
1891: for the group we are dealing with. If it finds that one of the recursions in
1892: the current group is on this list, it adjusts the offset in the list, not the
1893: value in the reference (which is a group number).

1894:

1895: Arguments:

1896: group points to the start of the group

1897: adjust the amount by which the group is to be moved

1898: utf8 TRUE in UTF-8 mode

1899: cd contains pointers to tables etc.

1900: save_hwm the hwm forward reference pointer at the start of the group

4911:     group with option changes, so the options change at this level. If this
4912:     item is right at the start of the pattern, the options can be
4913:     abstracted and made external in the pre-compile phase, and ignored in
4914:     the compile phase. This can be helpful when matching -- for instance in
4915:     caseless checking of required bytes.
4916:
4917:     If the code pointer is not (cd->start_code + 1 + LINK_SIZE), we are
4918:     definitely *not* at the start of the pattern because something has been
4919:     compiled. In the pre-compile phase, however, the code pointer can have
4920:     that value after the start, because it gets reset as code is discarded
4921:     during the pre-compile. However, this can happen only at top level - if
4922:     we are within parentheses, the starting BRA will still be present. At
4923:     any parenthesis level, the length value can be used to test if anything
4924:     has been compiled at that level. Thus, a test for both these conditions
4925:     is necessary to ensure we correctly detect the start of the pattern in
4926:     both phases.
4927:
4928:     If we are not at the pattern start, compile code to change the ims
4929:     options if this setting actually changes any of them, and reset the
4930:     greedy defaults and the case value for firstbyte and reqbyte. */

5691: /*****
5692: *      Check for anchored expression      *
5693: *****/
5694:
5695: /* Try to find out if this is an anchored regular expression. Consider each
5696: alternative branch. If they all start with OP_SOD or OP_CIRC, or with a bracket
5697: all of whose alternatives start with OP_SOD or OP_CIRC (recurse ad lib), then
5698: it's anchored. However, if this is a multiline pattern, then only OP_SOD
5699: counts, since OP_CIRC can match in the middle.
5700:
5701: We can also consider a regex to be anchored if OP_SOM starts all its branches.
5702: This is the code for \G, which means "match at start of match position, taking
5703: into account the match offset".
5704:
5705: A branch is also implicitly anchored if it starts with .* and DOTALL is set,
5706: because that will try the rest of the pattern at all possible matching points,
5707: so there is no point trying again.... er ....
5708:
5709: .... except when the .* appears inside capturing parentheses, and there is a
5710: subsequent back reference to those parentheses. We haven't enough information
5711: to catch that case precisely.
5712:
5713: At first, the best we could do was to detect when .* was in capturing brackets
5714: and the highest back reference was greater than or equal to that level.
5715: However, by keeping a bitmap of the first 31 back references, we can catch some
5716: of the more common cases more precisely.
5717:
5718: Arguments:
5719: code      points to start of expression (the bracket)
5720: options   points to the options setting
5721: bracket_map a bitmap of which brackets we are inside while testing; this
5722:             handles up to substring 31; after that we just have to take
5723:             the less precise approach
5724: backref_map the back reference bitmap

84:  *      Create bitmap of starting bytes      *
85:  *****/
86:
87: /* This function scans a compiled unanchored expression recursively and
88: attempts to build a bitmap of the set of possible starting bytes. As time goes
89: by, we may be able to get more clever at doing this. The SSB_CONTINUE return is
90: useful for parenthesized groups in patterns such as (a*)b where the group
91: provides some optional starting bytes but scanning must continue at the outer
92: level to find at least one mandatory byte. At the outermost level, this
93: function fails unless the result is SSB_DONE.
94:
95: Arguments:
96:   code      points to an expression
97:   start_bits points to a 32-byte table, initialized to 0
98:   caseless  the current state of the caseless flag
99:   utf8      TRUE if in UTF-8 mode
100:   cd        the block with char table pointers
101:
102: Returns:    SSB_FAIL    => Failed to find any starting bytes
103:             SSB_DONE    => Found mandatory starting bytes
104:             SSB_CONTINUE => Found optional starting bytes

72:

73: #include <ctype.h>

74: #include <limits.h>

75: #include <setjmp.h>

76: #include <stdarg.h>

```

77: #include <stddef.h>
78: #include <stdio.h>
79: #include <stdlib.h>
80: #include <string.h>
81:
82: /* When compiling a DLL for Windows, the exported symbols have to be declared
83: using some MS magic. I found some useful information on this web page:
84: http://msdn2.microsoft.com/en-us/library/y4h7bcy6\(VS.80\).aspx. According to the
85: information there, using __declspec(dllexport) without "extern" we have a
86: definition; with "extern" we have a declaration. The settings here override the
87: setting in pcre.h (which is included below); it defines only PCRE_EXP_DECL,
88: which is all that is needed for applications (they just import the symbols). We
89: use:
90:
91: PCRE_EXP_DECL    for declarations
92: PCRE_EXP_DEFN    for definitions of exported functions
93: PCRE_EXP_DATA_DEFN for definitions of exported variables
94:
95: The reason for the two DEFN macros is that in non-Windows environments, one
96: does not want to have "extern" before variable definitions because it leads to
97: compiler warnings. So we distinguish between functions and variables. In
98: Windows, the two should always be the same.
99:
100: The reason for wrapping this in #ifndef PCRE_EXP_DECL is so that pcretest,
101: which is an application, but needs to import this file in order to "peek" at
102: internals, can #include pcre.h first to get an application's-eye view.
103:
104: In principle, people compiling for non-Windows, non-Unix-like (i.e. uncommon,
105: special-purpose environments) might want to stick other stuff in front of
106: exported symbols. That's why, in the non-Windows case, we set PCRE_EXP_DEFN and
107: PCRE_EXP_DATA_DEFN only if they are not already set. */

53:  *      Validate a UTF-8 string      *
54:  *****/
55:
56: /* This function is called (optionally) at the start of compile or match, to
57: validate that a supposed UTF-8 string is actually valid. The early check means
58: that subsequent code can assume it is dealing with a valid string. The check
59: can be turned off for maximum performance, but the consequences of supplying
60: an invalid string are then undefined.
61:
62: Originally, this function checked according to RFC 2279, allowing for values in
63: the range 0 to 0x7fffffff, up to 6 bytes long, but ensuring that they were in
64: the canonical format. Once somebody had pointed out RFC 3629 to me (it
65: obsoletes 2279), additional restrictions were applied. The values are now
66: limited to be between 0 and 0x0010ffff, no more than 4 bytes long, and the
67: subrange 0xd000 to 0xdfff is excluded.
68:
69: Arguments:
70:  string    points to the string
71:  length    length of string, or -1 if the string is zero-terminated
72:
73: Returns:   < 0  if the string is a valid UTF-8 string
74:            >= 0 otherwise; the value is the offset of the bad byte
75: */

```
1: /* config.h. Generated from config.h.in by configure. */
2: /* config.h.in. Generated from configure.ac by autoheader. */
3:
4:
5: /* On Unix-like systems config.h.in is converted by "configure" into config.h.
6: Some other environments also support the use of "configure". PCRE is written in
7: Standard C, but there are a few non-standard things it can cope with, allowing
8: it to run on SunOS4 and other "close to standard" systems.
9:
10: If you are going to build PCRE "by hand" on a system without "configure" you
11: should copy the distributed config.h.generic to config.h, and then set up the
12: macro definitions the way you need them. You must then add -DHAVE_CONFIG_H to
13: all of your compile commands, so that config.h is included at the start of
14: every source.
15:
16: Alternatively, you can avoid editing by using -D on the compiler command line
17: to set the macro values. In this case, you do not have to set -DHAVE_CONFIG_H.
18:
19: PCRE uses memmove() if HAVE_MEMMOVE is set to 1; otherwise it uses bcopy() if
20: HAVE_BCOPY is set to 1. If your system has neither bcopy() nor memmove(), set
21: them both to 0; an emulation function will be used. */

43: /* There are three implementations of cancel cleanup.
44:  * Note that pthread.h is included in both application
45:  * compilation units and also internally for the library.
46:  * The code here and within the library aims to work
47:  * for all reasonable combinations of environments.
48:  *
49:  * The three implementations are:
50:  *
51:  * WIN32 SEH
52:  * C
53:  * C++
54:  *
55:  * Please note that exiting a push/pop block via
56:  * "return", "exit", "break", or "continue" will
57:  * lead to different behaviour amongst applications
58:  * depending upon whether the library was built
59:  * using SEH, C++, or C. For example, a library built
60:  * with SEH will call the cleanup routine, while both
61:  * C++ and C built versions will not.
62:  */
63:
64: /*
65:  * Define defaults for cleanup code.
66:  * Note: Unless the build explicitly defines one of the following, then
67:  * we default to standard C style cleanup. This style uses setjmp/longjmp
68:  * in the cancelation and thread exit implementations and therefore won't
69:  * do stack unwinding if linked to applications that have it (e.g.
70:  * C++ apps). This is currently consistent with most/all commercial Unix
71:  * POSIX threads implementations.

120:  * -----

```

121: *
122: *
123: * Module: pthread.h
124: *
125: * Purpose:
126: * Provides an implementation of PThreads based upon the
127: * standard:
128: *
129: * POSIX 1003.1-2001
130: * and
131: * The Single Unix Specification version 3
132: *
133: * (these two are equivalent)
134: *
135: * in order to enhance code portability between Windows,
136: * various commercial Unix implementations, and Linux.
137: *
138: * See the ANNOUNCE file for a full list of conforming
139: * routines and defined constants, and a list of missing
140: * routines and constants not defined in this implementation.
141: *
142: * Authors:
143: * There have been many contributors to this library.
144: * The initial implementation was contributed by
145: * John Bosson, and several others have provided major
146: * sections or revisions of parts of the implementation.
147: * Often significant effort has been contributed to
148: * find and fix important bugs and other problems to
149: * improve the reliability of the library, which sometimes
150: * is not reflected in the amount of code which changed as
151: * result.
152: * As much as possible, the contributors are acknowledged
153: * in the ChangeLog file in the source code distribution
154: * where their changes are noted in detail.
155: *
156: * Contributors are listed in the CONTRIBUTORS file.
157: *
158: * As usual, all bouquets go to the contributors, and all
159: * brickbats go to the project maintainer.
160: *
161: * Maintainer:

```

162: *   The code base for this project is coordinated and
163: *   eventually pre-tested, packaged, and made available by
164: *
165: *       Ross Johnson <rpj@callisto.canberra.edu.au>
166: *
167: * QA Testers:
168: *   Ultimately, the library is tested in the real world by
169: *   a host of competent and demanding scientists and
170: *   engineers who report bugs and/or provide solutions
171: *   which are then fixed or incorporated into subsequent
172: *   versions of the library. Each time a bug is fixed, a
173: *   test case is written to prove the fix and ensure
174: *   that later changes to the code don't reintroduce the
175: *   same error. The number of test cases is slowly growing
176: *   and therefore so is the code reliability.
177: *
178: * Compliance:
179: *   See the file ANNOUNCE for the list of implemented
180: *   and not-implemented routines and defined options.
181: *   Of course, these are all defined in this file as well.
182: *
183: * Web site:
184: *   The source code and other information about this library
185: *   are available from
186: *
187: *       http://sources.redhat.com/pthreads-win32/
188: *

332: *
333: * POSIX 1003.1-2001 Options
334: * =====
335: *
336: * Options are normally set in <unistd.h>, which is not provided
337: * with pthreads-win32.
338: *
339: * For conformance with the Single Unix Specification (version 3), all of the
340: * options below are defined, and have a value of either -1 (not supported)
341: * or 200112L (supported).
342: *
343: * These options can neither be left undefined nor have a value of 0, because
344: * either indicates that sysconf(), which is not implemented, may be used at
345: * runtime to check the status of the option.
346: *
347: * _POSIX_THREADS (== 200112L)
348: *          If == 200112L, you can use threads
349: *
350: * _POSIX_THREAD_ATTR_STACKSIZE (== 200112L)
351: *          If == 200112L, you can control the size of a thread's
352: *          stack
353: *          pthread_attr_getstacksize
354: *          pthread_attr_setstacksize
355: *
356: * _POSIX_THREAD_ATTR_STACKADDR (== -1)
357: *          If == 200112L, you can allocate and control a thread's
358: *          stack. If not supported, the following functions
359: *          will return ENOSYS, indicating they are not
360: *          supported:
361: *          pthread_attr_getstackaddr
362: *          pthread_attr_setstackaddr
363: *
364: * _POSIX_THREAD_PRIORITY_SCHEDULING (== -1)
365: *          If == 200112L, you can use realtime scheduling.
366: *          This option indicates that the behaviour of some

```

367: * implemented functions conforms to the additional TPS
 368: * requirements in the standard. E.g. rwlocks favour
 369: * writers over readers when threads have equal priority.
 370: *
 371: * `_POSIX_THREAD_PRIO_INHERIT` (== -1)
 372: * If == 200112L, you can create priority inheritance
 373: * mutexes.
 374: * `pthread_mutexattr_getprotocol` +
 375: * `pthread_mutexattr_setprotocol` +
 376: *
 377: * `_POSIX_THREAD_PRIO_PROTECT` (== -1)
 378: * If == 200112L, you can create priority ceiling mutexes
 379: * Indicates the availability of:
 380: * `pthread_mutex_getprioceiling`
 381: * `pthread_mutex_setprioceiling`
 382: * `pthread_mutexattr_getprioceiling`
 383: * `pthread_mutexattr_getprotocol` +
 384: * `pthread_mutexattr_setprioceiling`
 385: * `pthread_mutexattr_setprotocol` +
 386: *
 387: * `_POSIX_THREAD_PROCESS_SHARED` (== -1)
 388: * If set, you can create mutexes and condition
 389: * variables that can be shared with another
 390: * process. If set, indicates the availability
 391: * of:
 392: * `pthread_mutexattr_getpshared`
 393: * `pthread_mutexattr_setpshared`
 394: * `pthread_condattr_getpshared`
 395: * `pthread_condattr_setpshared`
 396: *
 397: * `_POSIX_THREAD_SAFE_FUNCTIONS` (== 200112L)
 398: * If == 200112L you can use the special `*_r` library
 399: * functions that provide thread-safe behaviour
 400: *
 401: * `_POSIX_READER_WRITER_LOCKS` (== 200112L)
 402: * If == 200112L, you can use read/write locks
 403: *
 404: * `_POSIX_SPIN_LOCKS` (== 200112L)
 405: * If == 200112L, you can use spin locks
 406: *
 407: * `_POSIX_BARRIERS` (== 200112L)

```

408: *           If == 200112L, you can use barriers
409: *
410: *   + These functions provide both 'inherit' and/or
411: *     'protect' protocol, based upon these macro
412: *     settings.
413: *

462:  * These limits are normally set in <limits.h>, which is not provided with
463:  * pthreads-win32.
464:  *
465:  * PTHREAD_DESTRUCTOR_ITERATIONS
466:  *      Maximum number of attempts to destroy
467:  *      a thread's thread-specific data on
468:  *      termination (must be at least 4)
469:  *
470:  * PTHREAD_KEYS_MAX
471:  *      Maximum number of thread-specific data keys
472:  *      available per process (must be at least 128)
473:  *
474:  * PTHREAD_STACK_MIN
475:  *      Minimum supported stack size for a thread
476:  *
477:  * PTHREAD_THREADS_MAX
478:  *      Maximum number of threads supported per
479:  *      process (must be at least 64).
480:  *
481:  * SEM_NSEMS_MAX
482:  *      The maximum number of semaphores a process can have.
483:  *      (must be at least 256)
484:  *
485:  * SEM_VALUE_MAX
486:  *      The maximum value a semaphore can have.
487:  *      (must be at least 32767)
488:  *
489:  */

141:
142: If the caller did not specify anything,
143: the default is REQUIRE_ORDER if the environment variable
144: POSIXLY_CORRECT is defined, PERMUTE otherwise.
145:
146: REQUIRE_ORDER means don't recognize them as options;
147: stop option processing when the first non-option is seen.
148: This is what Unix does.
149: This mode of operation is selected by either setting the environment
150: variable POSIXLY_CORRECT, or using `+' as the first character
151: of the list of option characters.
152:
153: PERMUTE is the default. We permute the contents of ARGV as we scan,
154: so that eventually all the non-options are at the end. This allows options
155: to be given in any order, even with programs that were not written to
156: expect this.
157:
158: RETURN_IN_ORDER is an option available to programs that were written
159: to expect options and other ARGV-elements in any order and that care about
160: the ordering of the two. We describe each non-option ARGV-element
161: as if it were the argument of an option with character code 1.

```

```

162: Using '-' as the first character of the list of option characters
163: selects this mode of operation.
164:
165: The special argument '--' forces an end of option-scanning regardless
166: of the value of 'ordering'. In the case of RETURN_IN_ORDER, only

239:   my_bcopy ((char *) temp,
240:             (char *) &argv[first_nonopt + optind - last_nonopt],
241:             nonopts_size);
242:
243:   /* Update records for the slots the non-options now occupy. */

```

```

244:
245: first_nonopt += (optind - last_nonopt);
246: last_nonopt = optind;
247: }
248:
249: /* Scan elements of ARGV (whose length is ARGC) for option characters
250:    given in OPTSTRING.
251:
252:    If an element of ARGV starts with '-', and is not exactly "-" or "--",
253:    then it is an option element.  The characters of this element
254:    (aside from the initial '-') are option characters.  If `getopt'
255:    is called repeatedly, it returns successively each of the option characters
256:    from each of the option elements.
257:
258:    If `getopt' finds another option character, it returns that character,
259:    updating `optind' and `nextchar' so that the next call to `getopt' can
260:    resume the scan with the following option character or ARGV-element.
261:
262:    If there are no more option characters, `getopt' returns `EOF'.
263:    Then `optind' is the index in ARGV of the first ARGV-element
264:    that is not an option.  (The ARGV-elements have been permuted
265:    so that those that are not options now come last.)
266:
267:    OPTSTRING is a string containing the legitimate option characters.
268:    If an option character is seen that is not listed in OPTSTRING,
269:    return '?' after printing an error message.  If you set `opterr' to
270:    zero, the error message is suppressed but we still return '?'.
271:
272:    If a char in OPTSTRING is followed by a colon, that means it wants an arg,
273:    so the following text in the same ARGV-element, or the text of the following
274:    ARGV-element, is returned in `optarg'.  Two colons mean an option that
275:    wants an optional arg; if there is text in the current ARGV-element,
276:    it is returned in `optarg', otherwise `optarg' is set to zero.
277:
278:    If OPTSTRING starts with `-' or `+', it requests different methods of
279:    handling the non-option ARGV-elements.
280:    See the comments about RETURN_IN_ORDER and REQUIRE_ORDER, above.
281:
282:    Long-named options begin with `--' instead of `-'.
```

283: Their names may be abbreviated as long as the abbreviation is unique
 284: or is an exact match for some defined option. If they have an

```

285: argument, it follows the option name in the same ARGV-element, separated
286: from the option name by a '=', or else the in next ARGV-element.
287: When `getopt' finds a long-named option, it returns 0 if that option's
288: `flag' field is nonzero, the value of the option's `val' field
289: if the `flag' field is zero.
290:
291: The elements of ARGV aren't really const, because we permute them.
292: But we pretend they're const in the prototype to be compatible
293: with other systems.
294:
295: LONGOPTS is a vector of `struct option' terminated by an
296: element containing a name which is zero.
297:
298: LONGIND returns the index in LONGOPT of the long-named option found.
299: It is only valid when a long-named option has been found by the most
300: recent call.
301:
302: If LONG_ONLY is nonzero, '-' as well as '--' can introduce
303: long-named options. */

List of Abbreviations, Acronym, and Symbols

Acronym/ Abbreviation	Description
SDM	System Data Model (formerly Satellite Data Model)
SPA	Space Plug-and-play Architecture
