This report is published in the interest of scientific and technical information exchange, and its publication does not constitute the Government's approval or disapproval of its ideas or findings.

Approved for public release; distribution is unlimited

REPORT DOCUMENTATION PAGE				Form Approved OMB No. 0704-0188	
Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing this collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.

Introduction

This document conveys the source code for the System Data Model (SDM, formerly “Satellite Data Model”), which was developed from 2004-2009 (through a variety of contract and in-house efforts) as part of the Air Force Research Laboratory (AFRL) Space Plug-and-play Architecture (SPA) research program. The software was developed as a middleware to explore plug-and-play concepts and to develop a better understanding of how to make join and discovery mechanisms operate in embedded systems.

This document only presents the source code of SDM in its entirety as a retired work to the public domain for study and follow-on research activities. The theory and operation of SDM will not be explained here, for a better understanding of SDM and SPA, the reader is referred to the bibliography following the Appendix.

The source code in its entirety is presented in the sole Appendix. AFRL does not endorse, warranty, or otherwise restrict the use of this code.

APPENDIX

File: sdm/app/test/README

1: SDM/app/test folder

2:

3: This folder and its subfolders contain ongoing test applications for the SDM system.

4: Documentation about these tests is mostly non-existent. This folder will be provided

5: with releases for those who may be interested.

6:

7: The SDM/app/test/ folder contains generic tests for the SDM system.

8:

9: The SDM/app/test/ClassTests/ folder contains tests for SDM classes.

10:

11: The SDM/app/test/DMTests/ folder contains tests specific to the Data Manager.

12:

13:

14:

15: Most of these applications should be started similarly to how the Process Manager would

16: start-up applications. That is, with the same command-line string.

17: \$./APPNAME TM-Address DM-Address SDM-PID

18: For example:

19: \$./SearchTest 127.0.0.1 127.0.0.1 56

9:  README:
10:
11:  This source file contains functions to build an xTEDS tree as the parser encounters the text.
12:  The functions are, in general, separated into new_*, link_*, merge_*, delete_*, and add_*
13:  names.
14:
15:  The new_* functions are used to allocate a structure type and initialize all pointer members to
16:  NULL. Also other member types should be initialized to some start value. Note that all new_*
17:  functions dynamically allocate the structure, and should be deleted using the corresponding
18:  delete_* function.
19:
20:  The link_* functions are used to link items of a list. Many of the structure types have members
21:  called "next" which refers to a link list. The link functions are used to link the instances.
22:
23:  The merge_* functions are used to add attributes and arbitrarily ordered elements to the structure.
24:  Notice that on many of the members of a structure, within these functions, there is a "else if"
25:  clause that prevents a memory leak that occurs if some attribute is specified in the xTEDS multiple
26:  times. This cannot be caught by the parser, and the funtions will simply throw away the most recent
27:  addition.
28:
29:  The delete_* functions free the dynamically allocated memory allocated by the new_* functions. If
30:  the structure member is a linked list, the delete function should recursively delete the list.
31:
32:  The add_* functions are used to simply add a pointer to a list member of a structure.
