Report Title

Design Automation Software for DNA-based Nano-Sensor Architecture

ABSTRACT

This project was developed in response to an RFA seeking innovations to create DNA molecules that self-assemble to support nanomolecular design. While the solicitation emphasized software to solve the challenges arising from the intrinsic chemistry of DNA, which is built from just four nucleotides (GACT), the premise of this project was that the design task could be rendered trivial if standard DNA were augmented extra nucleotides to give an "artificially expanded genetic information system" (AEGIS).

Student Metrics

This section only applies to graduating undergraduates supported by this agreement in this reporting period

The number of undergraduates funded by this agreement who graduated during this period: 0.00

The number of undergraduates funded by this agreement who graduated during this period with a degree in
science, mathematics, engineering, or technology fields:..... 0.00

The number of undergraduates funded by your agreement who graduated during this period and will continue
to pursue a graduate or Ph.D. degree in science, mathematics, engineering, or technology fields:..... 0.00

Number of graduating undergraduates who achieved a 3.5 GPA to 4.0 (4.0 max scale):..... 0.00

Number of graduating undergraduates funded by a DoD funded Center of Excellence grant for
Education, Research and Engineering:..... 0.00

The number of undergraduates funded by your agreement who graduated during this period and intend to
work for the Department of Defense 0.00

The number of undergraduates funded by your agreement who graduated during this period and will receive
scholarships or fellowships for further studies in science, mathematics, engineering or technology fields: 0.00

Date: April 30, 2012

Organization: Firebird Biomolecular Sciences LLC

Rationale

This project was developed in response to an RFA seeking innovations to create DNA molecules that self-assemble to support nanomolecular design. While the solicitation emphasized software to solve the challenges arising from the intrinsic chemistry of DNA, which is built from just four nucleotides (GACT), the premise of this project was that the design task could be rendered trivial if standard DNA were augmented extra nucleotides to give an "artificially expanded genetic information system" (AEGIS). These are shown in Figure 1.

Figure 1. The AEGIS components optimally designed to support nanostructure design (left); compare with the standard versions of the AEGIS components (right). R and "Function" indicate sites for potential functionalization of these structures.

Design of experiments to collect data to support software development

In anticipation of Phase 2, we have turned to experiments that need to be done to support key customers who will wish to use AEGIS DNA. This month we have focused on those who will want to use "ultra long" DNA (UL-DNA) constructs. This has focused on developing a bacterial strain that will be able to manage plasmids containing AEGIS DNA.

To this end, we asked what happens to Z/P containing DNA when introduced into *E. coli*. Here, plasmids containing an insert with targeted Z:P pairs were used to transform DH5 α and BL21-gold host bacteria (the strains are rec A1 recombination deficient, not SOS deficient; and recA+, respectively).

Surprisingly, having Z/P in the plasmid did not lower the transformation efficiency of the construct when compared to a control with an insert lacking Z:P base pairs. Fifty clones were screened for presence of the insert by PCR; only three did not have the insert. This means that the clones had not excised the insert and reformed the plasmid, which generally happens when an insert is toxic. Since these cells were not supplied with dZ:dP nucleoside or the Dm-dNK kinase they must have substituted natural nucleosides for them. Further, since the colony counts and growth rate between control insert and Z:P containing insert were the same, replacement of the Z:P pairs seems to happen quickly.

Sequencing of the insert contained in plasmids purified from these clones showed an interesting pattern of substitution (Table 1). All ZZ:PP dinucleotides were converted to CC:GG dinucleotides. This will be helpful when designing selections to create UL-DNA molecules.

As another rule, P was observed to always be converted to G or A, while Z is always converted to C or T. The rule suggests that the polymerase is matching size

Table 1. Sequencing of converted P:Z inserts from DH5 α and BL21-gold

Data Set	Target Sequence	# of sequences	P:Z to G:C	P:Z to A:T	Z:P to C:G	Z:P to T:A	% converted to G:C	% converted to C:G
1Z	APg/TZC	24	15	9			62.5	
2Z	APPg/TZZC	29	29	0			100	
2ZP	gPg gCCZC/							
	CZCCggPg	30	23	7	16	14	77	53

These results, showing predicable conversion of Z:P pairs, will be a key technology to support customers wishing to use the orthogonality of Z:P pairs to construct UL-DNA.
