ABSTRACT

On September 11, 2012, the U.S. Consulate in Benghazi, Libya, was attacked, resulting in the death of four United States citizens, including Ambassador Christopher Stevens. Prior to Benghazi, the Marine Corps Embassy Security Group (MCESG) held a total strength of about 1,400 Marines, of which 1,196 were Marine Corps Security Guards (MSGs). In response to the deadly attack, Congress authorized 1,000 new MSGs through the 2013 National Defense Authorization Act, creating additional protection for U.S. diplomatic facilities worldwide. In this thesis I examine the growth requirements needed to support the MCESG's expansion demands to produce MSGs at maximum capacity in the coming three to four years, and I propose an operational, easily adjustable methodology to assist MCESG operation personnel plans for expansion and future force sustainment. The methodology accounts for uncertainty in the decision-making process by incorporating Monte Carlo simulation techniques. I also provide in this thesis an easy to use interface built as a Visual Basic for Applications (VBA) UserForm, meant as a simple and effective tool that can assist planners in standardizing procedures at the operational level. The findings of the thesis indicate that the proposed methodology could yield significant savings in terms of manpower and training requirements for the MCESG.

ACKNOWLEDGMENTS

I would like to thank the faculty and staff of the Naval Postgraduate School's Graduate School of Business and Public Policy for providing me with an invaluable educational experience.

A special thank you to my advisors, Professors Don Summers and Simona Tick, for providing their expertise and guidance when it counted the most. This thesis would not have been possible without your help.

I would also like express a heartfelt thank you to my parents, Buddy and Susan Slack, without whom it would not have been possible for me to have such great opportunities in life.

Finally, and most important, I would like to extend my deepest gratitude to my wife, Jessica Slack, for her support for me and our children, Richard Logan and Evalina Grace Slack, during our time at the Naval Postgraduate School. My appreciation cannot be fully expressed.

GO GAMECOCKS!

ABOUT THE AUTHOR

Richard T. Slack, Major, United States Marine Corps, Student, Graduate School of Business and Public Policy. Major Slack earned a marketing/management degree in 1996 from the University of South Carolina and is a graduate of the United States Marine Corps Command and Staff College. Major Slack is an assault support helicopter pilot, having served as a CH-46E pilot in Iraq and a CH-53D pilot in Afghanistan. Upon graduation from the Defense Systems Analyst program at the Naval Postgraduate School in March 2013, Major Slack will report to the Marine Corps Systems Command, Quantico, VA.

I. INTRODUCTION

A. OVERVIEW

On September 11, 2012, the U.S. Consulate in Benghazi, Libya, was attacked, resulting in the death of four United States citizens, including the U.S. Ambassador, Christopher Stevens. Prior to the attacks, in Benghazi the Marine Corps Embassy Security Group (MCESG) held a total strength of approximately 1,392 Marines, of which 1,196 were Marine Corps Security Guards (MSGs). In the aftermath of this attack, “Congress authorized growth of up to 1,000 Marines for embassy security” (Marine Corps Embassy Security Group [MCESG], 2013) The MCESG expansion will start late in fiscal year (FY) 2013 or early FY 2014 and last through FY 2016. During this time, 53 new Marine Security Guard detachments will be established, and 975 additional MSGs will be trained. Of the 975 new MSGs, 117 will form a new Security Augmentation Unit (SAU) designed to rapidly respond from the MCESG in Quantico, VA. The mission of the SAU will be to augment the physical security shortfalls at designated U.S. diplomatic facilities around the globe.

B. OBJECTIVE

The objective of this thesis is to examine the growth requirements needed to support the MSG expansion demands and to propose an operational and effective decision support methodology to assist MCESG operation personnel plan for expansion and future force sustainment. During this research, I found that MCESG plans to produce MSGs at maximum capacity in the next three to four years. In this study, I analyze the trainee demands required for the expansion of the MCESG and propose a methodology that can assist the MCESG operations personnel plan for the expansion and future force sustainment. The proposed methodology is founded on an Excel based analytical approach, which relies heavily on simulation and is easily interfaced through a Visual Basic for Applications (VBA) UserForm. The model itself can be easily manipulated as operational needs dictate the requirements for expansion or sustainment. Once developed, the VBA UserForm is a simple and effective tool that can assist planners in standardizing procedures at the operational level.

C. ORGANIZATION OF THESIS

In the chapters that follow, I present a review of the MSG's background, a literature review, the data and assumptions used in the thesis, a methodology, and the analysis and findings from the applied methodology. This thesis ends with conclusions that provide a brief overview of the trainee demand findings and with recommendations for future research and implementation.

D. PROBLEM STATEMENT

Following the Benghazi attacks and Congress' authorization for the United States Marine Corps (USMC) to expand the MSG community by nearly half, the Department of State (DoS) and the MCESG have established the growth demands for the MSG expansion. Current research indicates that the MCESG plans on conducting MSG training at maximum capacity to meet these demands. The problem with a maximum capacity production plan is the *potential* for an excess supply of MSGs produced in the coming years. This could in turn have an impact on other USMC communities in the current force reduction.

E. RESEARCH QUESTION

What trainee demands are required to meet the demands for the MSG expansion authorized by Congress?

F. METHODOLOGY

I conducted the analysis for this thesis in three parts. First, I describe the model, then I describe how I simulated the model, and finally, I introduce Visual Basic for Applications (VBA). The development of this methodology was inspired mainly by an Australian Department of Defence study I came across in my research titled *Determining Training Demands for an Expanding Military Organisation*. The work in the Australian study disclosed techniques that helped build a foundation for the mathematical concepts and VBA UserForm described in the following chapters.

II. BACKGROUND

A. OVERVIEW

For almost 70 years, the USMC and the DoS have partnered to provide the global protection of classified U.S. information and diplomatic personnel with MSGs. The official USMC (n.d.-a.) website expounds on the origins of MSGs and the critical role they play in creating a safe environment for U.S. diplomatic posts around the world.

The origins of the modern MSG Program began with the Foreign Service Act of 1946, which stated that the Secretary of Navy is authorized, upon the request of the Secretary of State, to assign enlisted Marines to serve as custodians under the supervision of the senior diplomatic officer at an embassy, legation, or consulate. Using this act, the DoS and U.S. Marine Corps entered into negotiations to establish the governing provisions for assigning MSGs overseas. These negotiations culminated in the first joint memorandum of agreement, signed on December 15, 1948.

Since 1948, the MSG program has grown to over 1,000 Marines and 150 detachments worldwide. Each detachment is staffed with Marines that are designated with the Military Occupational Specialty (MOS) code 8156. The code is divided into two categories: detachment commanders (DetCos) and watchstanders (WSs). DetCos are sourced from staff non-commissioned officers (SNCOs) with either a rank of staff sergeant (E-6), gunnery sergeant (E-7), or master sergeant (E-8). The DetCos are assigned WSs from either the rank/grade of private first class (E-2), lance corporal (E-3), corporal (E-4), or sergeant (E-5).

The DoS assigns classified regional threat levels predicated the decision to staff MSGs at diplomatic facilities abroad. The regular size of an MSG detachment consists of one detachment commander and five WSs. Dependent on the threat level, a larger detachment may be posted at the mission. Larger MSG detachments are organized with two DetCos and 25 WSs. Subsequently, if the threat level is classified below a certain threshold, detachments may not be assigned to U.S. embassies or consulates. Table 1 shows the detachment size based on threat levels.

Table 1. MSG Detachment Size

Detachment Size	1/5	2/25
Threat level	Normal	High
Detachment Commanders	1	2
Watchstanders	5	25

Congress' call to expand the MSG program after the recent deadly consulate attacks will almost double its footprint. In a period of increased global security threats, this expansion is necessary to sustain the MSG mission. The following quote from the USMC (n.d.-b.) website explains the mission of the MSG:

The primary mission of the Marine Security Guard (MSG) is to provide internal security at designated U.S. diplomatic and consular facilities in order to prevent the compromise of classified material vital to the national security of the United States. The secondary mission of the MSG is to provide protection for U.S. citizens and U.S government property located within designated U.S. diplomatic and consular premises during exigent circumstances (urgent temporary circumstances which require immediate aid or action).

MCESG Headquarters (HQ), commanded by a Marine colonel, has added a new compound aboard Marine Corps Base Quantico in northern Virginia. In close proximity to the FBI Training Academy and Laboratory, the compound is opening in three phases with barracks, training facilities, and administrative buildings with a small-scale mock replica of a U.S. embassy. Construction should be complete in 2014. The MCESG commanding officer "is responsible to the deputy commandant (DC), Plans, Policies, and Operations (PP&O), Headquarters, U.S. Marine Corps [HQMC]" (USMC, n.d.-a). Among the duties of the colonel is the recruitment and training of new trainees. The following quote from the USMC (n.d.-b.) website explains in detail the responsibilities of the MCESG's commanding officer:

The commanding officer of the MCESG reports to the Commandant of the Marine Corps (CMC), exercising command, less operational supervision, of Marines assigned to MSG detachments. MCESG Headquarters is responsible for the screening, training, assignment, administration, logistical support of Marine Corps-unique items, and discipline of Marines assigned to the MCESG. The commanding officer, MCESG, also commands those Marines assigned to Headquarters, MCESG, and MCESG regional headquarters, and is the director, MSG School. MSG

School provides suitability screening and formal training for selected Marines to perform duties as MSGs at Foreign Service missions.

The MCESG organization is composed of nine regional HQs, each commanded by a Marine lieutenant colonel.

MCESG Region Commands report to the commanding officer of the MCESG and exercise command, less operational supervision, of Marines assigned to the MSG detachments in their respective regions. The MCESG Region Headquarters ensure the continued training, operational readiness, personnel administration, and logistical support, as well as the morale, welfare, and discipline of Marines assigned for duty to MSG detachments at designated U.S. diplomatic missions in order to support the Department of State in the protection of classified material at foreign posts. (USMC, n.d.-b)

As of February 2013, there are 152 active MSG detachments located in nine regions. Table 2 presents the nine active MCESG regional commands and the number of detachments they command.

Table 2. Regional HQs of the MCESG (February 2013)

Region	Headquarters Location	Area of Responsibility	Detachments
1	Frankfurt, Germany	Eastern Europe and Eurasia	17
2	Abu Dhabi, United Arab Emirates	India and Middle East	18
3	Bangkok, Thailand	East Asia and Pacific	18
4	Fort Lauderdale, Florida	South America	13
5	Frankfurt, Germany	Western Europe and Scandinavia	18
6	Pretoria, South Africa	East Africa	18
7	Frankfurt, Germany	North Africa and West Africa	18
8	Frankfurt, Germany	Central Europe	18
9	Fort Lauderdale, Florida	North America and Caribbean	14

The current manning of the MSG program, as of the 2nd quarter of FY 2013, has an end strength of 1,392 Marines. The organizational structure includes the following:

1. MCESG HQ is staffed by 127 Marines, which includes 14 Marines with the 8156 MOS. The 8156 MOS is a designation for Marines who have graduated from the MCESG's MSG training program for the purpose of serving at U.S. embassies and consulates.
2. Nine regional HQs currently manned with 83 non-MSG Marines.

3. There are 154 detachments (including two inactive) being supported by 1,196 MSGs. This breaks down into 156 detachment commanders (E-6, E-7, & E-8 ranks) and 1,026 watchstanders (WSs; E-2, E-3, E-4, & E-5 ranks).

Figure 1 displays the locations of the 152 MSG detachments established in 37 countries and nine regions.

Marine Corps Embassy Security Group Organization

Currently 152 detachments; 137 countries; 18 time zones; 9 regions
Location of detachment is determined by Department of State

1

Figure 1. Map of MCESG Organization
(MCESG, 2013)

B. POLICY CHANGE

The government revisited the value added to security by the presence of MSG detachments abroad after a U.S. consulate, without MSGs, was targeted and destroyed by terrorists. The following quote explains the attacks in more detail:

A series of terrorist attacks in Benghazi, Libya, on September 11–12, 2012, involving arson, small-arms and machine-gun fire, and use of rocket-propelled grenades (RPGs), grenades and mortars, focused on two U.S. facilities in Benghazi, as well as U.S. personnel en route between the two facilities. In addition, the attacks severely wounded two U.S. personnel, injured three Libyan contract guards and resulted in the destruction and abandonment of both facilities—the U.S. Special Mission compound (SMC) and Annex. (Department of State [DoS], 2013, p. 1)

The Benghazi attacks proved to be the catalyst for a policy change, which led to Congress authorizing an increase in the size of the MSG program over the next few years. This increase in strength will be vital to improving the stability and security of diplomatic missions overseas. After the attack, the DoS (2013) convened an Accountability Review Board (ARB) whose report stated that

the Benghazi attacks took place against a backdrop of significantly increased demands on U.S. diplomats to be present in the world’s most dangerous places in order to advance American interests and connect with populations beyond capitals, and beyond the host governments’ reach. (p. 2)

Upon review, “key recommendations were made in the following six areas: overarching security considerations; staffing high risk, high threat posts; training and awareness; security and fire safety equipment; intelligence and threat analysis; and personnel accountability” (DoS, 2013, p. 7). The focus of this thesis is on key recommendation 11, found under the overarching security considerations, which states the following:

11. The Board supports the State Department’s initiative to request additional Marines and expand the Marine Security Guard (MSG) Program as well as corresponding requirements for staffing and funding. The Board also recommends that the State Department and DoD [Department of Defense] identify additional flexible MSG structures and request further resources for the Department and DoD to provide more capabilities and capacities at higher risk posts. (DoS, 2013, p. 10)

The DoS has requested Congress to redirect about \$1.4 billion in appropriated funding for operations in Iraq towards these new ARB recommendations. Over \$550 million of this amount has been slated for the Marine Security Guard expansion.

C. MARINE CORPS EMBASSY GROUP EXPANSION

In the aftermath of the Benghazi attacks, “Congress authorized growth of up to 1,000 Marines for embassy security” (MCESG, 2013). The USMC’s expansion planning has been completed and has identified FY 2016 target growth and end strength requirements. The expansion plan for the MCESG will create 53 new detachments and 975 new MSG billet identification codes (BICs). It was discovered that the MCESG plans on conducting MSG production at maximum capacity to meet the growth demands. If the MSG training demand exceeds the organizational demands required, an excess supply of trained MSGs could emerge. It is the purpose of this thesis to analyze the train demand through a model that can be applied to the organizational demands of the MCESG.

D. SUMMARY

The purpose of this chapter is to give the reader the requisite knowledge to understand the convergence of the MCESG mission and relevant current events leading up to policy change, which forms the basis for the research in this thesis. In Chapter III, I review the literature that I discovered in the course of this research.

THIS PAGE INTENTIONALLY LEFT BLANK

III. LITERATURE REVIEW

A. OVERVIEW

The purpose of this literature review is to seek out the methods and techniques available for application to an organized approach in determining training demands.

B. TRAINING DEMANDS

Study by Wang, Vozzo, and Galanis (2005)

In a 2005 study, Jun Wang, Armando Vozzo, and George Galanis of the Australian Defence Science and Technology Organisation analyzed the calculation of training demand for an expanding military force. The study was aptly named *Calculating the Training Demand in an Expanding Military Organisation: An Analytical Solution*. Wang, Vozzo, and Galanis (2005) study outlined two analytical methods calculating the instructor training demands in an expanding military force. The impetus for this work was a “circular reference” error discovered in the spreadsheet formulas used to calculate the training demands in expanding organizations. The authors addressed training demands in two parts: steady state demand and expansion demand. Expansion demand is further addressed in two aspects: the *suck-up* training effect and the dynamic training effect. The suck-up effect causes shortages during periods of expansion when lower ranks are sourced to fill the increased number of higher ranks. Wang, Vozzo, and Galanis (2005) also observed that during expansion, an increased demand for instructors from combat units reduces the combat force while increasing the training demand. This increased demand is presented as the *dynamic* training effect.

Wang, Vozzo, and Galanis (2005) concluded that the dynamic training effect is the result of one of many training policies and may not be the optimal solution. They recommended further research to determine the training demands for their organization.

This study presents iterative and recursive views for addressing the instructor expansion problem. Although in this thesis I do not address instructor-staffing concerns, the logic presented in the Wang, Vozzo, and Galanis (2005) study helps formulate a foundation for identifying the training demands in Chapter IV.

Study by Yan, Chen, and Chen (2007)

This 2007 study by Shangyao Yan of Taiwan's National Central University, Chia-Hung Chen of Taiwan's Shu-Te University, and Miawjane Chen of Taiwan's National United University was conducted under the sponsorship of the National Science Council of Taiwan. The study developed "two stochastic models used for air cargo terminal manpower supply planning in long-term operations. These two long-term stochastic-demand planning models accounted for stochastic disturbances, which are usually representative of actual demand forecasts" (Yan et al., 2007, p. 1). Yan et al. (2007) based their stochastic models on two deterministic models, which were designed for long-term demand planning. It is the premise of Yan et al. that stochastic models are better planning tools due to the reflection of actual manpower demand fluctuations. In the following passage by Yan et al. (2007), random models are considered better than certain models when considering demand:

A planned terminal manpower supply plan is the basis for the real future operations. Real operations must fulfill the planning objectives by implementing the planned terminal manpower supply plan. Thus, the inter-relationship between the planned terminal manpower supply plan and the real operations must be kept in mind when dealing with real problems with stochastic manpower demands. When these real stochastic manpower demands are not considered, then deterministic demand models, based on the average (or projected) demand, will tend to use resources too tightly, resulting in an overly optimistic "optimal" terminal manpower supply plan. (Yan et al., 2007, p. 1)

The analysis and results of this study led the researchers to conclude that their premise was in fact true: Stochastic models were superior to deterministic models by 0.32%, on average. The stochastic-demand models are efficient for both terminal manpower supply planning and shift setting in long-term operations (Yan et al., 2007, p. 274).

Although the MCESG's growth demands are deterministic, overall FY training demands remain stochastic. The methods presented in this study provide a reference for the development of long-term planning operations.

Study by Wang, Egudo, and Galanis (2007)

In this 2007 study, *Determining Training Demand for an Expanding Military Organisation*, Jun Wang, Richard Egudo, and George Galanis of the Australian Defence

Science and Technology Organisation analyzed the “disadvantages of a training plan whereby instructors don’t return to the combat force after the expansion training period” (Wang, Egudo, & Galanis, 2007). Wang, Egudo, and Galanis (2007) conducted their study under the sponsorship of the Land Operations Division of the Defence Science and Technology Organisation. This main focus of Wang, Egudo, and Galanis’s (2007) study was to analyze the effects of surplus instructors on training demands once an expansion period of training has been completed. Surplus instructors create gaps, which need to be filled in the operating forces because these surplus instructors are at the training command. Wang, Egudo, and Galanis (2007) conducted an analysis of two plans: the “pay-back-instructor” plan and the “instructor-returning” plan. In this study, Wang, Egudo, and Galanis (2007) used two separate applications to determine training demand; one of these applications was an Excel-based analytical tool, and the other was a mixed-integer optimization model.

After analyzing the results, the authors concluded that the instructor-returning plan has greater returns than the pay-back-instructor plan. They determined that the instructor-returning plan reduced the training demand and reduced the cost of the workforce (Wang, Egudo, & Galanis, 2007).

Although I do not address instructors in this thesis, Wang, Egudo, and Galanis’s (2007) study presents an analytical approach, which provides insight for the planning and development of training demands through the framework of an analytical spreadsheet.

C. SUMMARY

In this chapter, I reviewed available literature about analytical approaches addressing training demands. In Chapter IV, I detail the data procured for use in the methodology and analytical approach.

THIS PAGE INTENTIONALLY LEFT BLANK

IV. METHODOLOGY

A. OVERVIEW

In this thesis I examine trainee demands required to support the expansion of the MCESG after the Benghazi attacks. During my research, I found that the current plan for expansion includes producing MSGs at maximum capacity. While the need and urgency to supply these MSGs to the nine regions is understandable, a maximum production plan could produce excess MSGs during a time of tight fiscal constraints.

The MCESG will, as always, provide the required number of MSGs to U.S. embassies and consulates. However, it is the premise of this thesis that a more precise production plan can be administered to fulfill the deterministic MSG growth demands for diplomatic posts. This thesis uses a methodology based on an analytic approach simulation and presented through the use of VBA. The techniques presented in this chapter may help planners in standardizing and formalizing procedures for determining trainee demands. The methodology used in this thesis is described in the following section.

B. MODEL SIMULATIONS

1. Background

Military organizations have used different forms of simulation for thousands of years, but it was not until mid-20th century that its use became common in business and industry. Today, much more advanced simulation techniques are used in the military and business thanks to the advent of the modern computer. The goal of simulation is “to try to duplicate the features, appearance, and characteristics of a real system” (Nagraj, Barry, & Stair, 2007). Simulations imitate real-world systems mathematically in order to assist solving real-world problems and shaping the decision-making process.

According to Nagraj et al. (2007), there are seven steps to the process of simulation. Figure 2 depicts the process of simulation.

Figure 2. Process of Simulation
(Nagraj et al., 2007)

Due to many of its advantages, simulation has been used extensively in industry as a modeling technique since circa the mid-20th century. The advantages of simulation are as follows:

1. Simulation is relatively straightforward and flexible.
2. Simulation can be used to analyze large and complex real-world situations that cannot be solved by using conventional decision models.
3. Simulation allows what-if types of questions.
4. Simulation does not interfere with the real-world system.
5. Simulation allows researchers to study the interactive effects of individual components or variables to determine which ones are important.
6. Simulation makes “time compression” possible.
7. Simulation allows for the inclusion of real-world complications that most decision models cannot permit. (Nagraj et al., 2007)

The advantages of simulation make it an attractive technique; however, the user should also be aware of the disadvantages such as the following:

1. Good simulation models can be very expensive.
2. Simulation does not generate optimal solutions to problems.
3. Managers must generate all the conditions and constraints for solutions that they want to examine.
4. Each simulation model is unique. (Nagraj et al., 2007)

A relatively modern simulation technique is the Monte Carlo simulation. It was developed during World War II to solve complex problems, which were too cumbersome

to calculate manually. Specifically, Monte Carlo simulation was created to deal with the unpredictable nature of the neutrons being tested for nuclear weapons. Thus, the Monte Carlo simulation technique has become a valuable tool for dealing with problems of chance, randomness, and probability. Probabilistic problems are encountered every day in business operations and decision-making. Some examples of these random-natured problems that simulation can address are as follows:

- product demand,
- lead time for orders to arrive,
- time between machine breakdowns,
- time between arrivals as a service facility,
- service time,
- time to complete a project activity,
- number of employees absent from work on a given day, and
- stock market performance. (Nagraj et al., 2007)

Above, Nagraj et al. (2007) indicated that the number one advantage of using Monte Carlo simulations is the flexibility and ease with which they can be run. This is captured in the following three steps:

1. Establish a probability distribution for each variable in the model that is subject to chance.
2. Using random numbers, simulate values from the probability distribution for each variable in the first step.
3. Repeat the process for a series of replications (also called runs, or trials). (Nagraj et al., 2007)

As mentioned previously, the Monte Carlo simulation technique was developed to handle complex problems of chance, which are too difficult to calculate by hand. Because of these qualities, computers are a natural tool that is used to conduct simulation. There are several categories of software packages that can be used for simulation, such as general-purpose programming languages and special-purpose simulation languages. General-purpose programming languages, such as Visual Basic or C++, offer the seasoned programmer a diverse range of options for developing simulations. Special-purpose simulation languages, such as Visual SLAM or GPSS/H, have more advantages over the general-purpose programming languages, but they require even more skill and programmer experience. For the novice or non-programmers who require a simulation capability, Microsoft's Excel software is the easiest program to build, generate random numbers, and run simple simulations. It is because of the "built-in ability to generate

random numbers and use them to select values from several probability distributions makes spreadsheets excellent tools for conducting simple simulations. Spreadsheets are also very powerful for quickly tabulating results and presenting them using graphs” (Nagraj et al., 2007).

In this section, I discuss generating random numbers using Excel’s more common features and probability distributions. Excel has a built-in random number generator feature, which is very simple to use. It requires activation of the Analysis Toolpak add-in, which provides the data analysis tools needed for statistical analysis. Among the analytical tools available, there is a random number generation feature that offers seven distributions. These seven distributions are uniform, normal, Bernoulli, binomial, Poisson, patterned, and discrete and are defined as follows:

- **Uniform:** Every random number has an equal chance of being selected. The user specifies the upper and lower limits.
- **Normal:** The random numbers correspond to a normal distribution. The user specifies the mean and standard deviation of the distribution.
- **Bernoulli:** The random numbers are either 0 or 1, determined by the probability of success that the user specifies.
- **Binomial:** This option returns random numbers based on a Bernoulli distribution over a specific number of trials, given a probability of success that the user specifies.
- **Poisson:** This option generates values in a Poisson distribution. A Poisson distribution is characterized by discrete events that occur in an interval, where the probability of a single occurrence is proportional to the size of the interval.
- **Patterned:** This option doesn’t generate random numbers. Rather, it repeats a series of numbers in steps that the user specifies.
- **Discrete:** This option enables the user to specify the probability that specific values are chosen. It requires a two-column input range: the first column holds the values, and the second column must equal 100%. (Walkenbach, 2010)

Equations can also be manually entered in workbook cells to replicate the same features. The basic format for generating random numbers is: =*RAND()*. When this format has been successfully entered into a cell, the formula generates a random number between 0 and 99 every time the keyboard F9 button is toggled.

The more common distributions used are the uniform, discrete, and normal probability distributions. They are formatted as follows in Excel:

Continuous uniform distribution = $a + (b - a) * RAND()$

Discrete uniform distribution = $INT(a + (b - a + 1) * RAND())$

Normal distribution = $NORMINV(RAND(), \mu, \sigma)$

Normal distribution with integers

= $ROUND(NORMINV(RAND(), \mu, \sigma), 0)$

= $ROUND(NORMINV(RAND(), \mu, \sigma), 0)$

C. VISUAL BASIC FOR APPLICATIONS (VBA)

VBA is Microsoft Excel's programming language, which is used to develop applications based on business models, often in the form of Excel spreadsheets. In the book *VBA for Modelers*, Christian Albright (2012) stated that the “application will take this information, build the appropriate model, optimize if necessary, and eventually present the back end to the user—a nontechnical report of the results, possibly with accompanying charts.” Applications can do this by using Excel spreadsheet models and transforming them into decision support systems (DSSs). DSSs “vary from very simple to very complex, but they usually provide some type of user-friendly interface so that a manager can experiment with various inputs or decision variables to see their effect on important output variables such as profit or cost” (Albright, 2012). To assist developers, Albright presented 10 guidelines for the development of readable and maintainable programs. They are as follows:

- Decide clearly what you want the application to accomplish.
- Communicate clearly to the user what the application does and how it works.
- Provide plenty of comments.
- Use meaningful names for variables, subs, and other programming elements.
- Use a modular approach with multiple short subs instead of one long one.
- Borrow from other programs that you or others have developed.
- Decide how to obtain the required input data.
- Decide what can be done at design time rather than at run time.
- Decide how to report the results.
- Add appropriate finishing touches. (Albright, 2012)

In Appendix D, there are examples of both DetCo and WS VBA UserForms for the model used in this thesis.

D. SUMMARY

Simulation is a straightforward and flexible technique that can give the user a method to replicate real-world problems with relative ease. The ability to conduct what-if type scenarios can increase the situational awareness of planners in developing courses of action in response to these scenarios. Although the MCESEG has always met and will continue to meet the needs of U.S. diplomatic facilities, simulation can assist operations personnel in determining training demands with more efficiency and confidence. I conduct and discuss simulations and results analysis in the next chapter.

V. DATA AND ASSUMPTIONS

A. OVERVIEW

In this chapter, I describe the data and assumptions used in the analysis. The data for this thesis were sourced from the DoS and the MCESG. The administrative data that were collected encompass all current and projected growth numbers required to sustain the expansion of the MCESG Program. This data was used to analyze the training demands for the FY production of DetCo and WS MSGs.

The numbers in Table 3 are the growth targets for MCESG and indicate an annual growth of 4%, 10%, 8%, and 8%; and 15%, 15%, 18%, and 13%, respectively, for the DetCo and WS population. Table 3 presents the expansion goals for the DetCo and WS MSG communities.

Table 3. MCESG Expansion Growth Targets

FY Growth	FY 13	FY 14	FY 15	FY 16	FY 17
Detachment commander	7	17	15	15	0
Watchstander	159	173	251	205	0

B. MCESG EXPANSION DATA

In the aftermath of the Benghazi attack, “Congress authorized growth of up to 1,000 Marines for embassy security” (MCESG, 2013, slide 2). This expansion of the MSG program has been developed in a four-phase approach. This authorized increase (expansion) was intended to accomplish the following four goals:

- open additional detachments identified and prioritized by Diplomatic Security (DS);
- increase tables of organization (T/Os) of existing detachments (the threat at each location dictates the number for each);
- create an MSG security augmentation unit in Quantico; and
- provide adequate administration and support to the increased operational structure (MCESG, 2013, slide 5).

1. Current Manning. Of the current total 1,392 Marines in the MCESG, it is the 8156 MOS (MSGs) comprised of DetCo and the WS that have been gapped in previous years. This gap is a result of the DoS and MCESG adjusting the official HQMC T/O for operations prior to the Benghazi, Libya, attack of September 11, 2012. This gap

reflects a shortfall of 263 MSGs. The current end strength for the 8156 MOS is 1,196 MSGs, which includes 14 MSGs posted in individual augment (IA) BICs at the MCESG HQs in Quantico, VA.

2. HQMC Approved T/O. The HQMC T/O end strength identifies a 1,655 Marine requirement to support the MCESG. This manning number reflects the increase of 263 MSGs to cover existing personnel gaps. DetCos comprise 10 of these gaps and WSs comprise 253 gaps. Once these gaps have been filled, the increase will bring the DetCos' end strength from 156 to 166 and raise the WSs' end strength from 1,026 to 1,279 MSGs. Under the existing HQMC T/O, the total number of detachments, regional HQ personnel, and MCESG HQ personnel remains unchanged.

3. Expansion T/O. The expansion plan calls for end strength of 2,432 Marines. The additional 712 MSGs breakdown into 16 new IA BICs at MCESG HQ, 45 new DetCo BICs, 534 new WS BICs, and 117 new SAU BICs.

The MSG program expansion plan will increase MSG end strength from 1,459 MSGs to 2,171 MSGs, raising the total MSG organizational manning levels from 1,655 to a target goal of 2,432 Marines. This increase reflects an overall growth of 777 Marines, 712 of which are the growth target for MSGs. The 712 MSG growths will be decomposed into 45 new DetCos and 534 new WSs.

4. Security Augmentation Unit. Following the Benghazi attacks, an intelligence assessment called for the capability to respond to emergency needs of U.S. embassies and consulates, which has led to the formation of the SAU. The mission of the SAU is described in the following quote from the MCESG (2013):

[The] primary mission: augment MSG detachments during periods of increased indications and warnings of an impending threat in the protection of U.S. citizens and property within U.S. diplomatic and consular premises. Be prepared to temporarily provide internal security at overseas U.S. diplomatic facilities that do not have MSG detachments. (slide 8)

The SAU T/O consists of a total of 122 Marines. There will be 117 MSGs, consisting of "nine detachment commanders and 108 watchstanders organized in nine security augmentation squads (SAS)" (MCESG, 2013, slide 12). Additionally, there will

be five Marines, including one officer and four enlisted Marines, providing supervision and support.

5. Additional Detachments. After an evaluation of the current level of 154 detachments (two inactive), “the Dept of State (DoS) identified 50 locations where Dets are needed” (MCESG, 2013, slide 2). The MCESG planning documents actually identify 53 new detachments, bringing the total number of detachments to 207. Of the 53 new detachments, only 38 have been identified as of this writing.

6. Support Personnel. The expansion plan calls for 65 new support personnel, including 38 new MCESG HQs Marines, 22 new regional HQs Marines, and five new SAU Marines. These 65 new support personnel bring the 712 new MSGs to a combined growth of 777 Marines for the MCESG organization. Figure 2 portrays the expansion goals of the MCESG.

Figure 3 succinctly presents the aforementioned data about the MCESG’s current manning, the official USMC T/O, and the desired end strength for the expansion T/O.

Figure 3. MCESG Expansion Plan
(MCESG, 2013)

C. MARINE SECURITY GUARD LIFE CYCLE

Upon graduation, the new MSGs are typically assigned to tour of duty of three years, rotating their assignments annually during the tour. During this three-year period, unforeseen events can prematurely shorten a tour of duty for some MSGs. These MSGs fall into two categories: goods of service (GoS) and Release for Cause (RfC). MSGs departing a tour of duty early in the GoS category leave because of circumstances outside their control, such as health issues. MSGs departing a tour of duty early in the RfC category leave for reasons such as non-judicial punishment (NJP). The sum of dropped MSGs categorized, like GoS and RfC, annually equates to the total MSG program drops for a given FY. I use the total program drops to determine the loss rate based on the average MSG strength during a given FY. Marines who complete a successful three-year tour of duty execute a PCS transfer out of MSG duty for their next USMC assignment

Figure 4 depicts the MSG life cycle.

Figure 4. Marine Security Guard Life Cycle Process

D. MARINE SECURITY GUARD CLASS DATA

The actual class data from FY 2006 until the second quarter of 2013 are located in Appendix A. This data was used to establish averages and probability distribution that is discussed further in Section D of Chapter VI.

E. MARINE SECURITY GUARD PRODUCTION CAPACITY

The MCESG convenes five MSG classes annually in Quantico, VA. Each class is constrained by lodging and class size to a maximum capacity of 240 students. The maximum capacity for DetCo students is 25 students per class or 125 students per year. The maximum capacity for WS students is 215 students per class or 1,075 students per year. Combined, the MCESG has a total production capacity of 1,200 MSGs per year who will be assigned to supply one of nine global MSG regions.

F. ASSUMPTIONS

I have made several assumptions about the data used in the model after communicating with subject-matter experts at MCESG. My first assumption is in regards to the loss rate for annual program drops, for which historical data is limited. The only data point that could be obtained were program drops for FY 2012, which indicated about 5%. Therefore, I assume 5% to be about average in the model but can account for a wider range of loss rates in the simulations. It would be logical to assume that because of the ongoing current reductions in military personnel, the limitations in training facilities, the attrition rate, and potential instructor staff shortfalls that no more than five seven week-long classes will convene annually. However, based on the urgency of the DoS Accountability Review Board after Benghazi and the new facilities under construction at Quantico, VA, it is a valid assumption that classes will steadily fill to maximum capacity in FY 2014. Finally, I assume that the end strength for both DetCos and WS have been steady-state prior to the Benghazi attacks. The assumptions for the model are as follows:

1. A 5% loss rate for annual program drops. Limited data was available for actual loss rates for the MSGs prior to FY 2012.
2. MCESG will not convene more than five classes annually.
3. MCESG will be able to recruit and fill each class at maximum capacity.

4. Maximum capacity training will begin in FY 2014.
5. Prior to FY 2013, DetCo MSG strength was 156; prior to FY 2013, WS MSG strength was 1026.
6. An MSG production drawdown or sustainment plan does not currently exist.

G. SUMMARY

This chapter is provided to familiarize the reader with the available data for the expansion plan for the MCESG. Chapter VI details the results and analysis of the model and simulation.

VI. RESULTS AND ANALYSIS

A. OVERVIEW

The MCESG is expanding its operations to meet worldwide security threats at U.S. diplomatic facilities. Since the attack at the U.S. consulate in Benghazi, Libya, Congress authorized the MCESG to expand its MSG end strength. As mentioned in Chapter IV, prior planning between the DoS and MCESG has identified the annual growth requirements (deterministic demand/parameters) needed to support this expansion. It is the purpose of this chapter to present a methodology that could be used to assist the MCESG in identifying the appropriate target trainee demand at the MSG schoolhouse. The target trainee demand is the requirement needed at the MSG schoolhouse to meet the annual growth demands after attrition and annual program drops. MCESG has two trainee demands: DetCos and WSs.

My research revealed that the MSG production plan for expansion entails producing MSGs at maximum capacity over the next four years, FYs 2013 through 2016. Additionally, it was determined that the MCESG does not have a standardized system to assist in the trainee demand planning for the expansion demands. In this chapter, I present a methodology to analyze the MSG production requirements in an effort to determine whether the maximum capacity production plan is the best strategy for the expansion. I present the analysis in the next chapter.

The logic behind the methodology of this model is based on a combination of the Wang, Egudo, and Galanis (2007) study and the financial accounting inventory equation. I also use future value formulas to project the PCS transfers in a given period based on historical data. The inventory equation is given as follows:

Beginning Inventory + Additions – Withdrawals = Ending Inventory (Stickney, 2010).

In this chapter, I use a three-part methodology: first, I describe the model; next, I describe how I simulated the model; and finally, I describe VBA.

B. THE MODEL FRAMEWORK

The goal of this model is to determine the target number of trainees (trainee demand) required to meet the MCESG's expansion demands. The outputs of the model include an annual target number of trainees, tr_t , for a three-year period; an annual expected number of annual graduates, g_e , for a three-year period; and an average number of trainees, a_t , and graduates, a_g , per class over a three-year period. The MCESG training cycle consists of five classes per annum. For the purposes of this model, Years 1, 2, and 3 are synonymous with FYs 2013, 2014, and 2015.

1. Model Limitations

The model application was limited to a three-year outlook in order to use actual graduate data available from prior years (PYs). MSG graduates are assigned to duty on three-year orders; therefore, I assume MSGs will execute PCS orders three years after graduation. However, for the analysis chapter, I use PCS estimation to project through expansion and into sustainment.

2. Parameters

The model in this thesis has two parameters and three variables. The parameters for this model are the expansion targets established by the MCESG. They are identified in this model as start strength, s_s , and target strength, s_t . Table 4 depicts the expansion target parameters required for FYs 2013, FY 2014, and FY 2015.

Table 4. MCESG Expansion Target Parameters

Position	Strength Type	FY 2013	FY 2014	FY 2015
DetCo	Starting Strength = s_s	$156 = s_{s1}$	$163 = s_{s2}$	$180 = s_{s3}$
	Target Strength = s_t	$163 = s_{t1}$	$180 = s_{t2}$	$195 = s_{t3}$
WS	Starting Strength = s_s	$1026 = s_{s1}$	$1185 = s_{s2}$	$1358 = s_{s3}$
	Target Strength = s_t	$1185 = s_{t1}$	$1358 = s_{t2}$	$1609 = s_{t3}$

The start strength, s_s , and the target strength, s_t , are used to determine the target demand and growth rate for the expansion period. Target demand is denoted by Δ and is calculated by the formula $\Delta = s_s - s_t$. The growth rate is denoted by r_Δ and is calculated by the formula $r_\Delta = \frac{\Delta}{s_s}$. Target demands and growth rates are calculated for Year 1, Year 2, and Year 3. Table 6 depicts the future planning output of Model 1 input parameters.

3. Historical Data

Prior year (PY) data is used for calculations of averages and loss rates in the model. The data available for use in the calculations are PY MSG graduates numbers, annual start strength, and annual end strength. PY data for the GoS and RfC categories were only available for FY 2012. This data indicated that 5% of the MSGs were dropped from the program that year. Therefore, I assume 5% to be the average loss rate, l_r , for the model.

a. Program Drops

Marines in the GoS category generally leave the MSG program prior to fulfilling their obligation due to circumstances outside their control (e.g., health issues). GoS is denoted by gos in the formulas. Marines in the RfC category generally leave the MSG program due to disciplinary actions, such as NJP. RfC is denoted by rfc in the formulas. The sum of gos and rfc are averaged to determine the annual MSG program drops. The average MSG program drops are denoted by d_a . The formula for the average program drops is

$$d_a = \left(\frac{gos_1 + rfc_1 + gos_2 + rfc_2 + gos_3 + rfc_3}{3} \right)$$

The average program drops, d_a , and the average annual MSG strength are used to calculate the loss rate. Loss rates are used to project the number of MSGs serving at diplomatic facilities that are dropped from the program annually. Loss rates are not the same as attrition rates, which would be used for Marines in training at the MSG Schoolhouse. This model uses graduation rates instead of attrition rates.

b. Annual Strength

Starting strength and ending strength data from the three PYs are used to calculate an average annual strength. The average strength is denoted by s_a and is calculated with the average drops, d_a , to determine the average historic loss rate. The loss rate, l_r , formula is $l_r = (\frac{d_a}{s_a})$. Once l_r has been determined the Year 1, 2, and 3 growth rates, r_{Δ} , are applied to estimate a year specific loss rate. Table 5 presents the loss rate formulas for Years 1, 2, and 3.

Table 5. Loss Rate Formulas

Average	l_r
Year 1	$l_{r_1} = l_r * r_{\Delta_1}$
Year 2	$l_{r_2} = l_{r_1} * r_{\Delta_2}$
Year 3	$l_{r_3} = l_{r_2} * r_{\Delta_3}$

c. PCS Transfers

Loss rates, l_r , are applied to actual graduates numbers, g_a , in PYs to accounting for average annual drops and project the expected number of PCS transfers. PCS transfers are denoted by t_e . Table 6 shows the formulas used to determine the expected transfers.

Table 6. Expected PCS Transfer Formulas

Year 1	$t_{e_1} = (g_a * (1 - l_r)^2) * (1 - l_{r_1})$
Year 2	$t_{e_2} = (g_a * (1 - l_r) * (1 - l_{r_1}) * (1 - l_{r_2}))$
Year 3	$t_{e_3} = (g_a * (1 - l_r) * (1 - l_{r_2}) * (1 - l_{r_3}))$

d. Required Graduates

Average program drops, d_a , and expected PCS transfers, t_e , are the two variables needed to determine the required graduates, or g_r . The sum of d_a and t_e equate

to the total number of personnel lost annually. The personnel lost from the program annually are denoted by l_p . The starting strength, s_s , is reduced by the l_p , calculating the new strength, denoted by s_n . The new strength is deducted from the target strength to project the required number of graduates needed to meet the expansion demand. Required graduates are annotated in an output report in Excel for Years 1, 2, and 3. Table 7 depicts the sequence for calculation of the required graduates.

Table 7. Required Graduate Formulas

Step 1	$g_r = s_t - (s_s - (t_e + d_a))$
Step 2	$g_r = s_t - (s_s - l_p)$
Step 3	$g_r = s_t - s_n$

e. Target Trainees

The required graduates, g_r , are divided by the selected graduation rate to project the required trainee demand needed to produce the required graduates needed to meet the expansion demand. The formula for required trainees is $tr_r = \frac{g_r}{r_g}$. Target trainees are annotated in an output report in Excel for Years 1, 2, and 3. Finally, an average spread of required graduates and target trainees is also annotated in an output report in Excel for Years 1, 2, and 3.

f. Notation

The following is a summary of the notation used in the model.

Δ = target demand (growth)

r_Δ = growth rate

s_s = expected start strength

s_n = new strength

s_e = ending strength

s_t = target strength

d_a = average drops

d_e = expected drops

s_a = average strength (3 year)

t_e = expected transfers

g_a = actual graduates

g_e = expected graduates

l_r = loss rate

n = years

r_g = graduation rate

tr_t = target trainees

a_t = trainee average

a_g = graduate average

l_p = lost personnel

C. THE SIMULATIONS FRAMEWORK

The model was simulated in 48 scenarios addressing both the DetCo and WS trainee demands. Of those scenarios, 24 were developed for each functional position and spread across four FYs, 2013–2016. Each FY scenario had six unique sub-scenarios developed for simulation. Figure 5 depicts the 24 scenarios simulated for DetCo and WS.

Figure 5. Diagram of Model Scenarios

Each model was constructed with two parameters and three variables. The scenarios' variables consisted of random graduation rates, set PCS transfers, and set program drops.

a. Parameters

The two parameters for this model are the starting strength and target strength. MCESG generated these growth parameters; therefore, I viewed them as constant in the model. The model parameters were displayed previously in Table 4.

b. Variables

This model has three variables: the expected PCS transfers, t_e , the program drops, d_a , and the graduation rates, r_g . The PCS transfers and program drops

are adjusted for each scenario with a new loss rate. The graduation rates are simulated throughout all scenarios.

PCS transfers should roughly equal the number of graduates from three years prior due to assignment on three-year orders. The loss rate, l_r , is applied to the population of FY graduates using a future value formula to estimate how many PCS transfers can be expected in a given period. This is done to account for graduates lost from the MSG program over the course of three years. The model uses actual FY 2010, FY 2011, and FY 2012 graduate numbers to estimate the number of expected PCS transfers in FYs 2013, 2014, and, 2015. The FY 2013 data is not currently available; therefore, the FYs 2006–2012 graduate averages are used to project the FY 2016 PCS transfers.

A loss rate is defined as the proportion of MSGs that leave the program prematurely due to health or legal issues. Limited data was available for actual loss rates for the MSGs prior to FY 2012. In FY 2012, 54 of 1,182 MSGs were program drops; therefore, I assume that the average annual loss rate is 5%. The 48 scenarios were conducted using 2%, 4%, 5%, 6%, 8%, and 10% loss rates.

Graduation rates are applied to the number of graduates calculated in the model to determine the number of trainees required to meet demand. Data were available from FY 2006 to the second quarter of 2013. During that period, 37 classes were completed, providing a solid base for simulating the graduation rates. Graduation rates were simulated in all 48 scenarios. Figure 6 depicts the flow of the simulations.

Figure 6. Diagram of Model Simulation Flow

D. VBA IMPLEMENTATION

The analytical method disclosed in Section B of this chapter is implemented in Excel through a VBA UserForm.

When the user opens the Excel document, they are presented with two worksheets, “Data” and “Calculations.” On the Data worksheet the user encounters two tables for input of data for both positions of the 8156 MOS. Each table has five categories for the user to input and maintain historic and future planning data: GoS, RfC, beginning strength, ending strength and graduates from PYs.

Above these Data worksheet tables is an “Interface” button, which produces a VBA UserForm when clicked. At the top of the UserForm, the planner has the option of selecting either the DetCo or WS position. The UserForm is automatically populated with the appropriate data from the Data worksheet once it appears or a new position is selected. Once the user has verified all the data, the “Execute” button should be clicked and a Results box appears with the requested results. To restart the UserForm for a new calculation, click “Ok” on the Results box and the UserForm reappears. The Data worksheet is displayed in Appendix D.

In the Calculations worksheet is the actual model, which also holds all the input and output data as well as the formulas used in the model's calculations. The Calculations worksheet is displayed in Appendix D.

E. INTERPRETATION OF THE RESULTS

1. Graduation Rates

First, I present the results of the graduation rate analysis that was done as a foundation in the model's development. Operating on the premise that the MCESG will be able to fill each class to maximum capacity, I analyzed the graduation rates, which were a key variable. Using the data from FY 2006 until the second quarter of 2013, I determined a computation of the graduation rates statistical averages to be 74% for DetCos students and 78% for WS students. Using these averages in the actual model, I created a what-if analysis chart based on the range of historic graduation rates. This chart gives the user an overview at a glance of the number of Marines required to begin MSG training in order to satisfy expansion demands. Enclosed in Appendix A are the graduation rate discrete probability distributions used in the simulations and the graduation rate descriptive statistics. The what-if analysis chart is located in Appendix B.

2. Maximum Capacity Production Simulation

A simulation was conducted for both DetCo and WS maximum capacity classes. This simulation was done to identify the expected production results of the maximum capacity plan for analysis against the model's results. The maximum capacity simulation of 125 DetCo trainees yielded an average of 92 DetCo MSGs per annum. The subsequent maximum capacity simulation of 25 DetCo trainees yielded an average of 18 DetCo MSGs produced per class. Conducting the same maximum capacity simulation for 1,075 WS trainees yielded an average of 834 WS MSGs per annum. Follow-on simulation of 215 WS trainees yielded an average of 168 DetCos produced per class. Table 8 displays the results of these simulations.

Table 8. Simulated Maximum Capacity Production Results

Maximum Capacity Data						
Position	DetCo			Watchstanders		
	Year 1	Year 2	Year 3	Year 1	Year 2	Year 3

Required graduates per class	15	18	18	131	168	168

3. Model Analysis

The model was first executed with the actual average graduation rates that assumed average loss rate, and the actual graduation data for PCS transfers. The model can be found in Appendix D. Table 9 displays the results of the model.

Table 9. Model Results

Output Data						
Position	DetCo			Watchstanders		
	Year 1	Year 2	Year 3	Year 1	Year 2	Year 3
Target trainees	83	95	92	739	579	820

Target trainees per class	17	19	18	148	116	164
Required graduates per class	12	14	14	115	90	128

4. Simulated Scenario Analysis

The model was next simulated in 48 different scenarios. Each scenario included simulated graduation rates and a different loss rate. Six scenarios were executed for each FY. The loss rate scenarios were 2%, 4%, 5%, 6%, 8%, and 10%, with 5% assumed to be the average loss rate. All of the loss rate scenarios results are depicted in graph format in Appendix E. Table 10 presents the numerical results of the 48 simulated scenarios.

Table 10. Simulated Scenario Results

The analysis of the maximum capacity training plan compared to the model output for FYs 2013 through 2016 shows an average three-year surplus of 29% and 44% for DetCo and WS MSGs, respectively. On average, this equates to a surplus of 26 DetCo and 286 WS MSGs trained annually between FYs 2013 through 2016. Table 11 displays the annual surplus percentages for each position.

Table 11. Surplus of Maximum Capacity Production Plan

Training Demand Analysis: Max vs Model

Delta	15	30	33	108	496	255
Max capacity trainee surplus	18%	32%	36%	15%	86%	31%

Further analysis of the maximum capacity plan against the high and low loss rate scenarios for FYs 2013 through 2016 was conducted. The maximum capacity plan still held surpluses against both of the simulated scenarios. On average, the maximum capacity plan had a surplus of 11% and 28% over the 10% loss rate scenario. Table 12

shows the surplus percentages for the simulated high and low scenarios versus the maximum capacity plan.

Table 12. Maximum Capacity vs. Simulated Maximum and Minimum Loss Rate Scenarios

Training Demand Analysis: Max vs Simulation								
	DetCo				Watchstanders			
	FY 13	FY 14	FY 15	FY 16	FY 13	FY 14	FY 15	FY 16
Max capacity trainees	98	125	125	125	847	1075	1075	1075
2%	89	102	99	104	766	571	835	753
Delta	9	23	26	21	81	504	240	322
Max capacity trainee surplus	10%	23%	26%	20%	11%	88%	29%	43%
Max capacity trainees	98	125	125	125	847	1075	1075	1075
10%	95	108	110	115	792	655	920	869
Delta	3	17	15	10	55	420	155	206
Max capacity trainee surplus	3%	16%	14%	9%	7%	64%	17%	24%

Of particular interest in the findings are the projected WS surplus rates for FY 2014. The surplus rates range from a high of 88% to a low of 64%, which is an outlier in the surplus data. My research concludes that this is due to the fact that the actual WS graduates in FY 2011 numbered 253 MSGs. The average number of WS graduates for the class from FY 2006 through the second quarter of 2013 is 359 MSGs, which means the FY 2011 class of WSs was 42% less than the average. The descriptive statistics for the average graduate rates can be found in Appendix A.

F. SUMMARY

In this chapter, I reviewed the model, results, and analysis of this thesis. Based on the analysis of the results, the model presents a potential planning tool that could assist decision-makers in determining the trainee demands of expansion and sustainment in the future.

THIS PAGE INTENTIONALLY LEFT BLANK

CONCLUSION AND RECOMMENDATIONS

G. SUMMARY

On September 11, 2012, the U.S. Consulate in Benghazi, Libya, was attacked, resulting in the death of four United States citizens, including the U.S. Ambassador, Chris Stevens. Prior to the attacks in Benghazi, the MCESG held a total strength of approximately 1,392 Marines, of which 1,196 were MSGs. In the aftermath of this attack, “Congress authorized growth of up to 1,000 Marines for embassy security” (MCESG, 2013). During my research, I discovered through subject-matter experts that the MCESG plans to produce MSGs at maximum capacity in the coming years. In this thesis, I analyzed the trainee demands required for the expansion of the MCESG and proposed an effective methodology that can assist the MCESG operations personnel plan for the expansion and future force sustainment. The proposed methodology is founded on a recent study from an Australian team (Wang, Egudo, & Galanis, 2007) that has been adapted to fit the decision environment faced by the MCESG operation personnel team. The model has also been adjusted to account for uncertainty in decision-making by incorporating Monte Carlo simulations to increase the efficiency of the decision-making process. In addition, I presented in this thesis an operational UserForm interface of the model that is easy to use and adjust to account for changing operational needs for expansion or sustainment.

H. MODEL EVOLUTION

The development of the methodology is based on a recent Australian Department of Defence study titled, *Determining Training Demands for an Expanding Military Organisation* (Wang, Egudo, & Galanis, 2007). The model in the Australian study used techniques that helped build a foundation for the mathematical concepts in this model and inspired the VBA UserForm developed for this thesis. I built upon the model used specifically for the MCESG operations personnel to determine trainee demands for the current expansion. Assumptions were made in the thesis model where information was lacking. However, the model stands as a proof of concept that development of such a

DSS can be useful at the MCESG and other training commands without such tools. The model developed in this thesis can be improved upon with

- additional data points to minimize assumptions,
- expanded UserForm capabilities to include graphs or charts,
- expanded model capabilities to assist in determining instructor demands in the training command, and
- expanded model capabilities to project trainee demands for classes; this model averages the annual outputs among the five classes and could be refined to better serve the planning purposes of the MCESG.

I. MODEL FINDINGS

The findings of this thesis indicate that the proposed methodology could yield significant savings in terms of manpower and training requirements for the MCESG. During simulation, it was determined that the surplus of DetCos could range from 3% to 26%, dependent on a high or low loss rate. It was also determined that the surplus of WSs could range from 7% to 88%, dependent on a high or low loss rate. When the model was run using the average loss rate, 5%, and the average graduation rates, it was calculated that the maximum production capacity trainee plan could yield a surplus of approximately 86% more WSs in FY 2014 alone. Based on these findings, it appears that the methodology used in this thesis could be of use for operational planners in the future. This model's results should be considered supplemental and advisory in nature to the MCESG's planning efforts.
